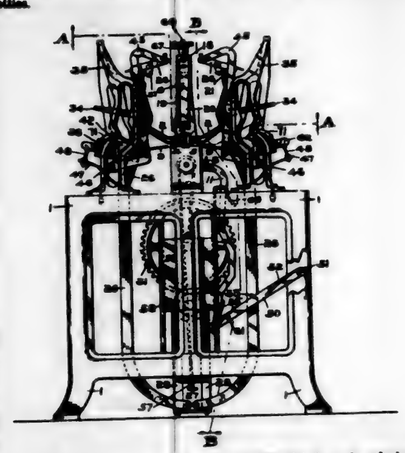
3. In a labeling-machine, a label-support, means over the label-support for stopping the upward movement of the bottle, label-carriers for elevating the labels from the support to the under side of the bottle, brushes for affixing the labels that follow said label-carriers in their upward movement, a label-holder for centrally engaging the labels lengthwise of the bottle, and means for moving the same upward between the label-carriers and brushes against the labels on the under side of the bottles.



4. In a labeling-machine, means for holding labels against the bottle or the like while being affixed made to conform substantially to the shape of the bottle lengthwise and mounted so as to rock and adjust itself to different shapes of bottles.

5. In a labeling-machine, means for holding labels against the bottle or the like while being affixed that is made to conform substantially to the shape of the bottle lengthwise, a bar or support to which said label-holder is centrally pivoted so as to rock, and a spring to limit the rocking movement thereof.

6. In a labeling-machine, means for holding labels against the bottle or the like while being affixed consisting of a bar lengthwise of the bottle, a support on which said bar is pivotally mounted so as to rock, and cushions connected with said bar and extending beyond the same and made to conform substantially to the form of the bottle lengthwise.

7. In a labeling-machine, means for holding labels against the bottle or the like while being affixed which consists of a channeled bar, and pieces of resilient material pivoted in the channel thereof near their center so they will rock and which are made to conform substantially to the bottle lengthwise.

8. In a labeling-machine, the label-holder apparatus consisting of the bar 8 with the channel 75 therein, the bar 11 to which the bar 8 is centrally pivoted, the spring 12 mounted on the pin 74 in the bar 11 and acting against the bar 8 to limit its rocking movement, the resilient blocks 13 and 14 centrally pivoted in the channel 75 of the bar 8, and the springs 76 in said channel and acting against said blocks to limit their rocking movement, substantially as shown and described.

9. In a labeling-machine, the label-holder 8, the bar 11 on which the same is mounted, the bar 50 pivoted at one end of the framework of the machine and at its other end to said bar 11, a spring for elevating said bar 50, a spring tending to force the upper end of the bar 11 and the label-holder inward, and means for limiting the inward movement thereof.

10. In a labeling-machine, oppositely-located pairs of brushes made to conform to the neck and body of the bottle for affixing the labels to the different parts of the bottle or the like, and independent means for mounting and controlling the movement of the oppositely-located brushes.

11. In a labeling-machine, the combination of the brushes 9, the rods 16 to which the same are secured, the bars 45 to which said rods are secured, means for actuating said bars 45, and the standards 35 with a guideway therein for guiding and controlling the lateral movement of said rods and brushes, substantially as set forth.

12. In a labeling-machine, brushes for affixing labels to the bottle or the like, the rods 16 on which they are mounted, the bars 45 to which said rods are secured, the vertically-movable bars 26 to which said bars 45 are pivoted at their upper ends, the standards 35 provided with the guideways therein and rollers 46 on said bars 45 that run in said guideways, substantially as shown and described.

13. In a labeling-machine, a label-carrier plate, the pivotally-mounted bar 21 with its lower end inturned and hinged to said label-carrying plate, arms 23 rigidly connected with the label-carrying plate and extending about the inturned end of the bar 21, and a set-screw 22 in the arm 23 that acts against the bar 21, substantially as set forth.

14. In a labeling-machine, a pair of label-carrying plates, a paste-pad under each plate, a paste-applying apparatus, means for vertically moving the label-carriers, a bell-crank pivoted to said vertically-moving means that when actuated moves the paste-plates into engagement with the paste-applying apparatus, a stationary means to engage and cause the actuation of said bell-crank, and a spring for moving the label-carrying plates inward when the bell-crank is released.

15. In a labeling-machine, the paste-box 38, the cross-rod 41, the hooks 40 connected with the paste-box, the extension 62, the support 47, and the adjustable plate 48 combined, substantially as shown and described.

16. In a labeling-machine, a label-support, and means for holding the labels on said support that leaves the side edges of said labels exposed and free to be engaged on their upper edges.

17. In a labeling-machine, means for affixing the labels, the bars 26 for supporting said means, the cross-head 27 to which said bars are pivoted, means for reciprocating the cross-head 27, the weight 56, a stationary pulley, and a cable running over said pulley from the cross-head to the weight to support and elevate the latter.

705,883. GENEALOGICAL CHAIN RECORD. FATTIE W. GEE, New York, N. Y. Filed Apr. 1, 1901. Renewed Dec. 19, 1901. Serial No. 86,535. (No model.)

Claim.—1. A genealogical chain record having as record devices for each individual of the family, a series of record elements adapted for receiving inscriptions, said elements being loosely coupled together in multiple and each element having about its margin a plurality of holes to receive the coupling devices.

2. A genealogical chain record having as record devices for each individual of a family, a series of flat or disk-like record elements adapted for receiving inscriptions and open chain-links loosely coupling together said record elements, the elements having a plurality of holes in their margins to receive said open links.

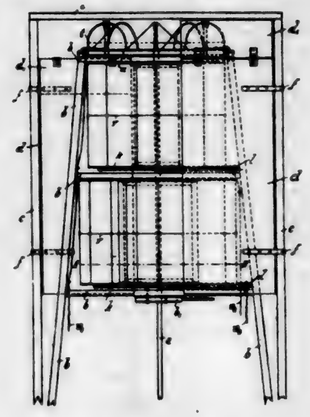
3. A genealogical chain record composed of disk-like or flat elements coupled loosely together and adapted to receive inscriptions, each of said elements having three coupling-apertures, and means for coupling said elements together.

705,884. AIR-MOTOR. ERASH GLOWACKI, Miskolcz, Austria-Hungary. Filed Aug. 2, 1901. Serial No. 70,696. (No model.)

Claim.—1. In a wind-motor, the combination of a staging, a motor provided with cells and adjusting-plates pivoted to the staging for protecting portions of the motor from the wind, said plates being provided with adjustable flaps, substantially as described.

2. A drum for a wind-motor consisting of an axle, a frame thereon provided with a bar *h* extending therefrom, another bar *k* pivoted on the axle, means for connecting the bars to each other, ribs *p* pivotally connected to the frame, and supporting material to form cells, a cord *r* connecting the cells to each other, and means on the bar *k* cooperating with the ribs to cause two of the ribs to follow the motion of the bar when the bars are moved apart and toward each other, substantially as described.

3. A drum for a wind-motor consisting of an axle, a frame thereon provided with a bar *h* extending therefrom, another bar *k* pivoted on the axle and having segmental portions provided with slots *i*, means for connecting the bars *k* and *h* to each other, ribs *p* pivotally connected to the frame, and supporting material to form cells, pins *s* on two of the ribs, engaging the slots *i*, and means connecting the cells to each other in such manner that when the bars *k* and *h* are moved apart to cause the pins *s* to move in the slots *i*, the cells will be folded up, substantially as described.



4. In a wind-motor, the combination with a staging, of an axle having bearings thereon, and a drum consisting of a frame *g* on the axle provided with a bar *h* and another bar *k* pivoted on the axle, said bar *k* being segmental at the sides and having curved slots *i*, a folding heel-piece *l* on the end of the bar *k* having an eye adapted to engage a pin *m* attached to the bar *h*, a rim *n* on the frame *g*, ribs *p* pivoted to said rim at top and bottom and inclosed in stretched cloth to form cells, pins *s* on two ribs engaging the slots *i* in the bar *k* and a cord *r* running around the cells in rings to draw them together when the bars *k* and *h* are moved apart to cause the pins *s* to move in the slots *i*, substantially as described.

5. In a wind-motor, the combination with a staging, of an axle having bearings thereon and a disk *u* on the axle provided with cells formed by upright ribs *t* with cloth stretched thereon and on the disk *u*, cords *v* connecting the cells on each half of the disk and another cord *x* fastened to one disk and passing over rollers to a catch for raising and lowering the cells, substantially as described.

6. In a wind-motor, the combination with a staging, of an axle having bearings thereon and a disk *u* on the axle provided with funnel-shaped cells formed by curved upright steel ribs *t* and cloth stretched on said ribs and on the disk *u*, cords *v* laterally connecting the cells on both halves of the disk arranged to raise the disks when one of them is raised and another cord *x* fixed to one cell and passing over rollers to a spring-catch *w* held by a pin *y*, substantially as described.

7. In a wind-motor, the combination with a staging, of an axle having bearings thereon, and a drum consisting of a frame *g* on the axle provided with a bar *h* and another bar *k* pivoted on the axle, said bar *k* being segmental at the sides and having curved slots *i*, a folding heel-piece *l* on the end of the bar *k* having an eye adapted to engage a pin *m* attached to the bar *h*, a rim *n* on the frame *g*, ribs *p* pivoted to said rim at top and bottom and inclosed in stretched cloth to form cells, pins *s* on two ribs engaging the slots *i* in the bar *k*, a cord *r* running around the cells in rings to draw them together when the bars *k* and *h* are moved apart to cause the pins *s* to move in the slots *i*, and means for releasing said heel-piece while the drum is rotating, substantially as described.

8. In a wind-motor, the combination with a staging, of an axle having bearings thereon and a disk *u* on the axle provided with cells formed by upright ribs *t* with cloth stretched thereon and on the disk *u*, cords *v* connecting the cells on each half of the disk, another cord *x* fastened to one disk and passing over rollers to a catch for raising and lowering the cells, and means for releasing said catch while the disk is rotating, substantially as described.

9. In a wind-motor, the combination with a staging, of an axle having bearings thereon and a disk *u* on the axle provided with funnel-shaped cells formed by curved upright steel ribs *t* and cloth stretched on said ribs and on the disk *u*, cords *v* laterally connecting the cells on both halves of the disk arranged to raise the disks when one of them is raised, another cord *x* fixed to one cell and passing over rollers to a spring-catch *w* held

by a pin *y*, and means for releasing said catch *w* while the disk is rotating, substantially as described.

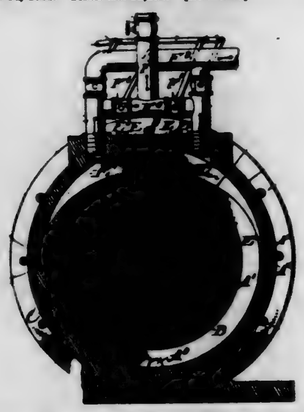
10. In a wind-motor, the combination with a staging, of a vertical axle having bearings thereon, drums on the axle provided with cells, a disk on the axle provided with upright cells and adjusting-plates pivoted on the frame for protecting portions of the drums from the wind, said plates being provided with adjustable flaps, substantially as described.

11. In a wind-motor, the combination with a staging, of a vertical axle having bearings thereon, drums on the axle provided with foldable cells, a disk on the axle provided with vertical foldable cells and adjusting-plates pivoted on the frame for protecting portions of the drums from the wind, substantially as described.

12. In a wind-motor, the combination with a staging, of a vertical axle having bearings thereon, drums on the axle provided with foldable cells, a disk on the axle provided with vertical foldable cells, and adjusting-plates pivoted on the frame for protecting portions of the drums from the wind, said plates being provided with hinged flaps for protecting portions of the disks and their cells from the wind, substantially as described.

13. In a wind-motor, the combination with a staging, of a vertical axle having bearings thereon, drums on the axle provided with foldable cells and means for maintaining said cells in an unfolded position, a disk on the axle above the drums provided with vertical foldable cells, and means for maintaining said cells unfolded, and means for folding either or both sets of cells while the drums and disks are rotating, substantially as described.

705,885. **ROTARY ENGINE.** FRANK G. GROVE, Leroy, Va. Filed Mar. 14, 1902. Serial No. 98,327. (No model.)



Claim.—1. In a rotary engine, a cylinder and piston-holder, a piston therein, an abutment at the upper portion of said cylinder, apertured cam-blocks at opposite sides of said abutment, and a by-pass extending from the aperture in said cam around the end thereof substantially as specified.

2. In a rotary engine, a cylinder and piston-holder, a piston therein, an abutment at the upper portion of said cylinder, cam-blocks at opposite sides of said abutment having apertures therethrough, by-passes extending from said apertures around the lower ends of said cam-blocks, conducting-pipes communicating with each of said cams, a steam-pipe communicating with said conducting-pipes and provided with cocks which are alternately opened and closed, and an exhaust-pipe communicating with said conducting-pipes and provided with valves which are alternately opened and closed, substantially as specified.

3. In a rotary engine, a cylinder and piston-holder, a piston therein, an abutment at the upper portion of said cylinder, cam-blocks at opposite sides of said abutment having apertures therethrough, conducting-pipes communicating with each of said cams, a steam-pipe communicating with said conducting-pipes and provided with cocks which are alternately opened and closed, an exhaust-pipe communicating with said conducting-pipes and provided with valves which are alternately opened and closed, levers extending from said cocks, a reversing-bar connecting said levers, and L-shaped packings disposed within an annular recess on the opposite ends of said piston-holder to bear against the piston-heads, substantially as specified.

4. A piston for a rotary engine, comprising opposite sections each having at one end a thickened portion provided with a recess and at the opposite end a tongue to fit the recess in the corresponding section and provided with a spring-recess between its ends, and a coiled spring of sufficient diameter to extend within the recess of each section, substantially as specified.

5. In a rotary engine, a casing having at opposite sides a seat, apertured cam-blocks adapted to rest at their lower ends upon said seats and having their upper ends secured to said casing, a by-pass extending from the aperture in said block around said seat, a cylindrical piston-holder, and pistons carried by said holder and normally projected therefrom under spring tension, substantially as specified.

6. In a rotary engine, a casing having at opposite sides a seat, apertured cam-blocks adapted to rest at their lower ends upon said seats and having their upper ends secured to said casing, a by-pass extending from the aperture in said block around said seat, a cylindrical piston-holder, pistons carried by said holder and normally projected therefrom under spring tension, an abutment between upper ends of said cam-blocks and comprising longitudinally-movable sections normally projected in opposite directions to each other, substantially as specified.

7. In a rotary engine, a casing having at opposite sides a seat, apertured cam-blocks adapted to rest at their lower ends upon said seats and having their upper ends secured to said casing, a by-pass extending from the aperture in said block around said seat, a cylindrical piston-holder, pistons carried by said holder and normally projected therefrom under spring tension, an abutment between upper ends of said cam-blocks and comprising longitudinally-movable sections normally projected in opposite directions to each other, segmental L-shaped packings disposed within similar recesses provided in the ends of said piston-holder, and means for admitting motive power to the aperture in one of said cams and exhausting from the opposite one, substantially as specified.

8. In a rotary engine, a cylinder having an apertured cam portion within its upper segment, feed and exhaust connections communicating with the said cam portion, an abutment between said connections, by-pass channels extending from the apertures at the opposite ends of the cam portion and around the ends thereof, a piston-holder provided with a transverse slot, a piston comprising separate members located within said slot, a spring between said members for projecting the ends thereof beyond said slot, and a spring beneath extending between the base of said slot and piston, substantially as specified.

705,886. **FASTENING DEVICE.** RAY W. GROVE, Lewistown, Mont. Filed Apr. 21, 1902. Serial No. 103,847. (No model.)

Claim.—1. A fastening device comprising two keepers and a bar, the ends of which are insertible into said keepers, said keepers being provided with means for holding said ends of said bar therein, said means consisting at one end of a laterally-movable spring-finger connected with the keepers and a plurality of notches or recesses formed in the side of the bar and in connection with which the spring-finger operates, substantially as shown and described.

2. The herein-described fastening device comprising two keepers, a bar, the ends of which are insertible into said keepers, one end of said bar being provided with a notch or recess and the keeper with a spring-finger adapted to enter the same at the other end of the bar being provided with a plurality of notches or recesses and the keeper with a laterally-movable spring-finger adapted to enter the same, substantially as shown and described.

705,887. **POWDER-PUFF.** MARIE L. GUHAER, Guymard, N. Y. Filed Mar. 12, 1901. Serial No. 50,833. (No model.)

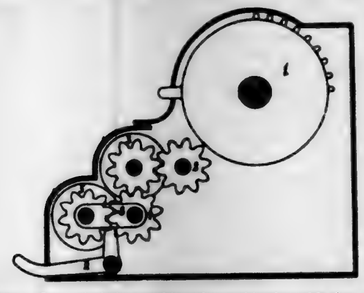
Claim.—1. In a combined powder-receptacle and powder-puff, a flexible bag having a permeable base, a neck portion comprising a hollow stem and substantially parallel plates between which the upper edge of said bag is adapted to be received and clamped, and a stopper adapted to close said stem and serve as a handle, substantially as described.

2. In a combined powder-receptacle and powder-puff, a flexible bag having a permeable base, and a neck portion comprising an exteriorly-screw-threaded stem, a plate rigidly supported thereby and a second plate substantially parallel therewith adapted in connection with said screw-threads to engage the upper edge of said bag and clamp it against said first-mentioned plate, substantially as described.

3. In a combined powder receptacle and pad, a flexible bag having a permeable base, a removable neck portion comprising an interiorly and exteriorly screw-threaded hollow stem, a plate rigidly attached thereto

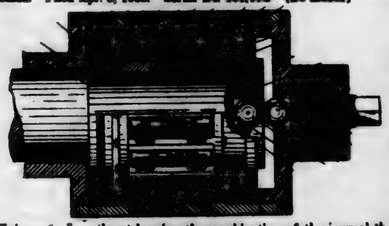
whereby the mouth of said bag is distended and pressure is exerted on the contents of said bag, a second plate substantially parallel therewith adapted in connection with said exterior threads to engage the edges of the mouth of said bag and clamp it against said first-mentioned plate and a screw-threaded stopper adapted in connection with said interior screw-threads to close said stem and also serve as a handle, substantially as described.

705,888. **CALCULATING-MACHINE.** OSKAR HAHAN, Friedenau-Berlin, Germany, assignor to Ernst Schmeler, Berlin, Germany. Filed Mar. 26, 1902. Serial No. 100,633. (No model.)



Claim.—In a calculating-machine, the combination with the registering-drum having a gear connected therewith and a second gear meshing with said first-named gear for driving the drum, of a second registering-drum having a gear connected therewith, a link pivoted at the axis of said second drum, an idler-gear journaled in the free end of said link and meshing with said last-named gear, and a bell-crank lever having one arm adapted to bear on the under side of said link and its other arm adapted to serve as an operating-handle, substantially as described.

705,889. **THRUST-BEARING.** ALBERT E. HENDERSON, Toronto, Canada. Filed Apr. 8, 1902. Serial No. 101,644. (No model.)



Claim.—1. In a thrust-bearing the combination of the journal the journal-box, antifriction thrust-balls interposed between the end of the journal and journal-box, a peripheral flange for the journal, an annular flange for the journal-box opposed to the peripheral flange, and auxiliary thrust-balls interposed between the annular and peripheral flanges, substantially as specified.

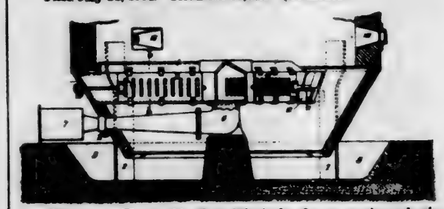
2. In a thrust-bearing the combination of the journal, having in its end a centrally-located ball-chamber, a journal-box having an end cap fitted with a longitudinal bore registering with the ball-chamber of the journal, contacting thrust-balls contained in the ball-chamber and bore respectively, and an adjusting-screw fitted into the bore to adjust the thrust-balls to each other, substantially as specified.

3. In a thrust-bearing the combination of the journal, having in its end a centrally-located ball-chamber, a journal-box having an end cap fitted with a longitudinal bore registering with the ball-chamber of the journal, contacting thrust-balls contained in the ball-chamber and bore respectively, an adjusting-screw fitted into the bore to adjust the thrust-balls to each other, and resilient cushions contacting the balls in the ball-chamber and adjusting-screw, substantially as specified.

4. In a thrust-bearing the combination of the journal, having in its end a centrally-located ball-chamber, a journal-box having an end cap fitted with a longitudinal bore registering with the ball-chamber of the journal, contacting thrust-balls contained in the ball-chamber and bore respectively, an adjusting-screw fitted into the bore to adjust the thrust-balls to each other, resilient cushions in the ball-chamber and adjusting-screw and contacting the balls, a radial flange for the journal opposed to an annular flange for the journal-box and auxiliary thrust-balls interposed between the annular and radial flanges, substantially as specified.

5. In a thrust-bearing, the combination of a journal having a recess in its outer end, said recess having a greater diameter than depth, a journal-plate opposed to the end of the journal provided with a bore in alinement with said recess, an adjustable screw mounted in said bore to provide a recess in the inner end of the plate of lesser depth than the diameter of the bore, and balls mounted in the recesses projecting respectively beyond the outer faces of the journal and the journal-plate, said balls contacting to receive the end thrust.

705,840. **GAS-PRODUCER.** JAMES A. HERRICK, Jonkintown, Pa. Filed July 26, 1901. Serial No. 69,840. (No model.)



Claim.—1. The combination of the body of a gas-producer, having an ash-hopper at the base of the same, with a twyer-box structure projecting into the ash-hopper from the sides of the same, said twyer-box structure being located above the bottom of the hopper so as to provide a sealing-body of ashes in the hopper below the twyer-box structure, the laterally-extending portions of the twyer-box structure having openings therein for the escape of air into the mass of ashes surrounding the same, and the bottom of the hopper being some distance above the ash-supporting bed or platform whereby access to the body of ashes at all points between said ash-supporting bed and the bottom of the hopper is permitted, substantially as specified.

2. The combination of the body of a gas-producer having an ash-hopper at the bottom, a sealing-pit into which said ash-hopper projects and which extends entirely around said hopper, and a twyer-box structure projecting laterally into the producer and located above the top of the sealing-pit whereby the latter is accessible at all points for the removal of ashes, substantially as specified.

3. The combination of the body of a gas-producer having an ash-hopper at the bottom with a twyer-box structure projecting laterally into said hopper from the sides of the same, said twyer-box structure having openings both in its sides and bottom for the escape of air, and the bottom of said structure being above the bottom of the ash-hopper, substantially as specified.

4. The combination of the body of a gas-producer with a series of twyer-boxes projecting laterally into said producer from the sides of the same, the laterally-extending portions of said twyer-boxes having openings through which the air can escape and an air-injector communicating with said twyer-boxes where they meet at the center of the producer, substantially as specified.

5. The combination of a gas-producer, with a twyer-box structure located in the lower portion of the producer and having sides with openings through which the air can escape, damper-plates movable on said sides of the twyer-boxes so as to vary the area of the escape-openings therein, and means for introducing air under pressure into said twyer-boxes, substantially as specified.

6. A gas-producer having in the lower portion of the same a twyer-box structure having laterally-extending portions with air-escape openings therein, in combination with means for introducing air under pressure into said twyer-box structure, and refractory blocks mounted alongside of the laterally-extending portions of the twyer-box structure, and removable in order to permit access to the sides of said twyer-boxes for cleaning purposes, substantially as specified.

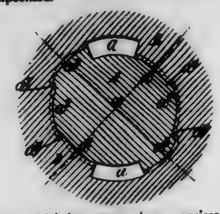
705,841. **BREECH BLOCK AND CHAMBER FOR ORDNANCE.** CARL HOLMSTRÖM, Glasgow, Scotland. Filed Jan. 3, 1902. Serial No. 88,867. (No model.)

Claim.—1. A breech-block which in cross-section comprises a series of concentric steps of different radii joined by surfaces other than radial with respect to the axis of the block so that the locking-surfaces can all be formed with continuous or uninterrupted screw-threads for the purpose specified.

2. A breech-block which in cross-section comprises a series of concentric steps of different radii joined by inclined surfaces substantially as and for the purpose specified.

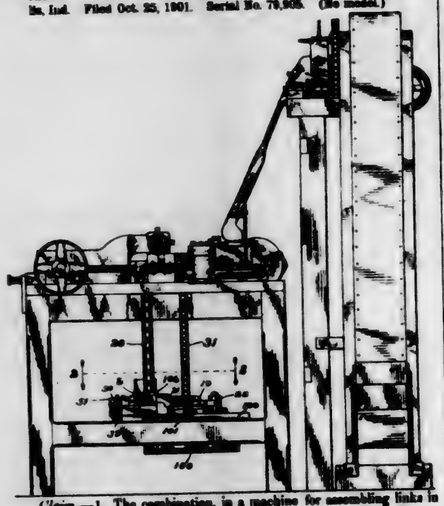
3. A breech-block which in cross-section comprises a series of concentric steps of different radii joined by inclined surfaces that are approxi-

nately tangential to the concentric surfaces of larger radius and curved where they meet the concentric surfaces of smaller radius substantially as and for the purpose specified.



4. A breech-block which in cross-section comprises a series of concentric steps of different radii joined by curved surfaces of ogee formation substantially as and for the purpose specified.

705,842. MACHINE FOR ASSEMBLING LINKS IN MAKING CHAIN BELTS. JOHN C. HOWE, Indianapolis, Ind., assignor, by direct and mesne assignments, of eleven-twentieths to Daniel H. Moroney, Jacob Wohlfeld, Julius M. Kaminsky, and Isaac Bachrach, Indianapolis, Ind. Filed Oct. 25, 1901. Serial No. 79,905. (No model.)



Claim.—1. The combination, in a machine for assembling links in making chain belts, of a suitable chute for introducing the links to the machine, a plunger for moving each link sidewise as it emerges from the chute into engagement with the preceding link, mechanism for drawing the chain along a distance equal to the length of a link after the last-stated movement, means actuated by the link as it is moved sidewise for throwing said mechanism into operation, and means for automatically throwing said mechanism out of engagement as the chain moves.

2. The combination, in a machine for assembling links in making chain belts, of a suitable chute for delivering the links to the machine, suitable mechanism for drawing the chain away as the links are assembled, a plunger for moving each link sidewise into engagement with the preceding link, a vibrating bar for operating said plunger, a cam-wheel for operating said vibrating bar, a slide-block engaging with said cam-wheel and with said bar, and means for adjusting the connection between said bar and said block, whereby the point to which the plunger shall move may be accurately determined.

3. The combination, in a machine for assembling links in making chain belts, of suitable mechanism for drawing the chain along as the links are assembled, a plunger for moving said links into assembled relations from the point where they are introduced into the machine, a vibrating bar for operating said plunger, a movable pivot for said vibrating bar whereby the length of the stroke of said plunger may be adjustably determined, a wheel revolving in proximity to said bar having a cam-groove in its periphery, a slideway alongside said wheel, a block mounted in said slideway and having a projection engaging with said cam-groove, and a stud adjustably secured to said block and engaging with said vibrating bar, whereby the point to which said bar shall move may be adjustably determined.

4. The combination, in a machine for assembling links in making chain belts, with the link-assembling mechanism, of a plunger for moving the links, a vibrating bar for operating said plunger a slide-block for operating said bar having a suitable adjustable stud connecting the block and the bar whereby the relative position of the two may be adjustably determined, and means for reciprocating said slide-block.

5. The combination, in a machine for assembling links in making chain belts, of a plunger for moving the links successively into position, a sprocket-wheel for drawing off the chain as the links are assembled, a ratchet-wheel on the same shaft with said sprocket-wheel, a vibrating arm on the end of said shaft, a pawl on said vibrating arm adapted to engage with said ratchet-wheel, a spring-pin on said arm adapted to hold said pawl out of engagement, a plunger adapted to be operated in one direction by the link when forced sidewise and having an arm which engages with said spring-pin to release the pawl and also having a pin extending over a tailpiece on said pawl whereby the same is raised out of engagement with the ratchet-wheel on its reverse movement, substantially as set forth.

6. The combination, in a machine for assembling links in making chain belts, of mechanism for drawing the belt forward as the links are assembled, a ratchet-and-pawl device for propelling the same, means for holding the pawl out of engagement except immediately after the link is assembled, means actuated by said link as it is assembled for throwing the ratchet-and-pawl devices into engagement, and means for automatically throwing said ratchet and pawl out of engagement as the chain moves forward after the link is assembled.

7. The combination, in a machine for assembling links in making chain belts, of mechanism for moving the links successively into assembled relation, mechanism embodying adjustable sprocket-wheel-supporting devices and a removable sprocket-wheel for moving the chain as the links are assembled, and means for adjusting said chain-moving mechanism to different positions whereby different-sized sprocket-wheels may be used to accommodate and handle different-sized links, substantially as set forth.

705,843. WIRE-STRETCHING MACHINE. HOOPER HYDE, Nashville, Tenn. Filed Feb. 3, 1902. Serial No. 92,456. (No model.)

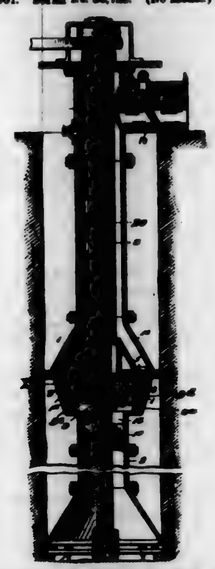
Claim.—1. In a wire-stretcher, a bar comprising an intermediate section, side sections secured on opposite sides thereof, having their ends projecting beyond the ends thereof, a hook on one side of said bar, a wire-guide secured between the projecting ends of the side sections at one end of said bar, a drum disposed between the projecting ends of the side sections at the opposite end of the bar and having its bearings therein, a ratchet-wheel revoluble with the drum and disposed on the outer side of one of the side sections, a pawl having a slot and on the outer side of the last-mentioned side section, a pivot in said slot, the pawl being loose thereon, engaged with the ratchet-wheel and provided with a counterweighting-arm extending rearwardly from said pivot, said counterweighting-arm having at its rear end a vertically and laterally extended hook engaging the inner side of the last-mentioned side section, disposed to move in a recess in the intermediate section, and forming a loose pivot at the rear end of the counterweighting-arm, substantially as described.

2. In a wire-stretcher, the combination of a support, a drum, a ratchet-wheel revoluble with the drum, a pawl having a slot, a pivot in said slot, the pawl being loose on said pivot, engaged with said ratchet-

wheel and having a counterweighting-arm extending rearwardly from said pivot and provided with a vertically and laterally extended hook disposed to move in a recess in the support and forming a loose pivot at the rear end of the counterweighting-arm, for the purpose set forth, substantially as described.

3. In a wire-stretcher, a bar comprising an intermediate section, side sections secured on opposite sides thereof having their ends projecting beyond the ends thereof a hook on one side of said bar, a wire-guide secured between the projecting ends of the side sections at one end of said bar, a drum disposed between the projecting ends of the side sections at the opposite end of the bar and having its bearings therein, means to rotate said drum and means to prevent reverse rotation thereof when the stretcher is in operation, substantially as described.

705,844. PUMP MECHANISM. EDMUND M. IVENS, New Orleans, La.; HARRY K. IVENS administrator of said Edmund M. Ivens, deceased. Filed Apr. 30, 1901. Serial No. 58,738. (No model.)



Claim.—1. In a pump mechanism as described; a lifting-pipe, and an outlet-pipe, a casing joining the two pipes, having a central inlet at the bottom joined with the lift-pipe, and annularly-disposed outlets discharging into the outlet-pipe, projections on the inner surfaces of the casing, whose inner edges are in a plane vertical with the pump-disk, said projections being inclined in the direction of the movement of the pump-disks from the bottom of the casing up to the outlets, and a centrifugally-acting pump-disk, operating with pump-casing, whose blades have vertically-disposed projecting surfaces, and whose outer extremities are held to travel close up to the vertical face of the casing projections, all being arranged substantially as shown and for the purposes described.

2. In a pump mechanism as described, a pump-casing, having a central bearing, and annularly-disposed outlets at the top, an offtake-pipe into which all of the outlets discharge, said casing having a single central inlet at the bottom, a shaft engaging the casing-bearing, a centrifugally-operating pump-disk thereon, whose blades have vertical outer edges, and curved impacting surfaces, adapted to throw the fluid toward the casing-wall, guide-lugs projected inwardly from the casing, having their inner face in a vertical plane to oppose the outer vertical edge of the disk blades, said guide-lugs being inclined from the bottom of the casing up to the annularly-disposed discharge-openings of the casing, substantially as shown and for the purposes described.

3. In a pump mechanism as described, the combination with the casing, and the centrifugally-operating pump-disk held therein, said casing having an outlet in the top, and an inlet in the bottom, an offtake-pipe connected with the outlet, and a water-feed discharging into the top of the casing for mixing up the material lifted by the pump-disk into the casing, for the purposes described.

4. In a mechanism as described, the casing, the centrifugally-operating pump-blades, said casing having an annular outlet and an offtake-pipe at the top, and a central inlet at the bottom, a water-feed pipe held within the offtake-pipe, discharging into the casing, and having a feed-lateral at the upper end, projected outside the offtake-pipe, substantially as shown and described.

5. The combination with the casing, comprising a lower part having converging sides, and a central opening in the bottom, and an annular discharge in the top, an upper or cap member extended over the annular discharge and terminating with an offtake, the upper and lower members having central bearing portions, the casing having a series of inwardly-projecting guide-lugs inclined from the bottom up, and in the direction of the movement of the pump-disk and having straight inner faces; of the shaft 3, and the pump-disk mounted thereon to rotate therewith, said disk having radial webs terminating in blades, filling the lower part of the casing, their outer ends having straight edges to travel in close proximity to the straight faces of the guide-lugs, substantially as shown and for the purposes described.

6. In a pump mechanism, including a casing, joined with the intake and offtake pipes, and a centrifugally-acting pump, operating within the casing; of detachable lugs on the inner wall of the casing for deflecting the water-column upwardly at an angle, and annularly.

7. The combination with the intake and offtake pipes; of the pump-casing, said casing consisting of a bottom section, having its walls converging downwardly, said section having a central opening in the bottom into which the lift-pipe discharges, a series of radially inwardly projecting guide-lugs on the wall of said casing-section, said stops being inclined upwardly at an angle in the direction of the movement of the pump-shaft and having vertical faces, said lower section having an annular discharge with which the said lugs coöperate, said discharge connecting with the offtake; of the shaft 4, the pump-disk mounted thereon, said disk comprising a hub, webs projected radially therefrom, blades forming an integral part of the webs, having their upper and lower edges running close to the top and bottom walls of the lower casing-section, and their vertical edges adapted to run close to the vertical face of the guide-lugs, all being arranged substantially as shown and described.

8. The combination with the intake and offtake pipes, and the drive-shaft; of the pump-casing, consisting of a lower section having a central pendent portion formed with a step-bearing to receive the drive-shaft, said lower section having its vertical wall diverging upwardly, a series of inwardly-projecting lugs on said wall, said lugs extending the full height of the said section, and inclined upwardly in the direction of movement of the shaft, and having their inner faces straight-faced, the pump-disk, having radial blades, whose upper and lower edges are adapted to run close to the top and bottom of the lower section, and its outer edges straight-faced, to run close to the straight faces of the aforesaid lugs, the top wall of the lower section having an annular discharge in line with the said lugs, and an upper casing-section, adapted to receive the fluid discharged from the lower section, and deflect it to the offtake, as set forth.

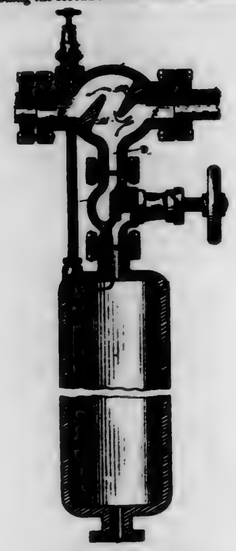
9. As an improvement in pumps of the character described, a pump-casing comprising a bottom part having a central inlet in the base thereof, a pendent portion joined with the inlet, and adapted to connect with the lift-pipe, said portion having a central bearing member 5, and a solid disk part of a diameter equal that of the pump-disk, and adapted to form the top of the disk-holding chamber of the casing, said member 5 also having radial projections 5^a, to extend over the annular discharge from the disk chamber, a cap member 1^a, the shaft 3, journaled in the bearings 5^a and 1^a, of the member 5 and the pendent portion aforesaid, respectively, the pump-disk having blades, whose upper and lower edges travel close to the plate 5, and the bottom of the disk chamber, and guide-lugs projected radially inward from the walls of the casing into the disk compartment thereof, the inner faces of which oppose the outer vertical edges of the disk blades, all being arranged substantially as shown and for the purposes described.

705,845. AMMONIA-SEPARATOR. VICTOR JOHNSON, St. Louis, Mo. Filed Mar. 26, 1902. Serial No. 99,975. (No model.)

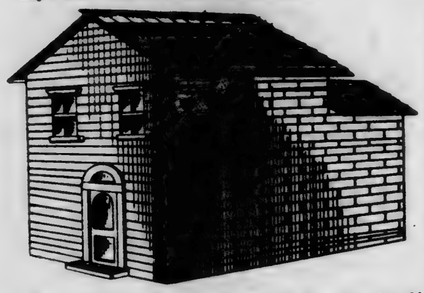
Claim.—1. In an ammonia-separator, the trap 5 adapted to be incorporated into the ammonia-pipe; said trap comprising a horizontal spherical body cored to form the inlet-opening 7, and the outlet-opening 8 in horizontal alinement, and the branch outlet-opening 9 extending downwardly half-way between the openings 7 and 8; the baffle-wall 10 extending downwardly and backwardly immediately inside of the opening 7; the baffle-wall 11 extending upwardly and forwardly immediately in front of the opening 8; a receptacle connected to the outlet 9; and a pipe running from the receptacle and communicating with the ammonia-pipe; substantially as specified.

2. In an ammonia-separator, a trap adapted to be incorporated into the ammonia-pipe, and having the baffle-wall 10 extending downwardly and backwardly in the forward part of the trap, and having the baffle-wall 11 extending upwardly and forwardly in the rear part of the trap; a receptacle connected to the trap; a valve controlling the connection; a

second connection leading from the receptacle to the ammonia-pipe; and a second valve controlling the second connection; substantially as specified



705,846. ARTIFICIAL-STONE FACING FOR BUILDINGS. THOMAS KELLY and FRANK G. BARBER, West Superior, Wis. Filed May 3, 1902. Serial No. 105,736. (No specimens.)

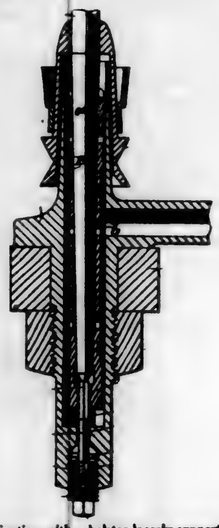


Claim.—1. In a device of the type set forth, the combination with the wall or the like, of a series of vertical laths secured thereto and a series of horizontal laths secured to the vertical laths, and a plastic composition applied to the said laths and completely inclosing the horizontal laths, with a series of slabs applied to the said plastic composition, while the latter is in a plastic state, substantially as described.

2. In a device of the type set forth, the combination with the wall or the like, of a series of suitably-spaced vertical laths secured to the said wall, and a series of suitably-spaced horizontal laths carried by the vertical laths, with a plastic composition applied to the said series of laths and engaging the said wall, the plastic composition entirely surrounding the horizontal laths and receiving a series of slabs on its outer surface, the slabs being secured solely by contact with the plastic composition, and having their edges in abutting engagement, substantially as described.

705,847. SPINDLE-BEARING. JOHN KILBURN, Belmont, Mass., assignor to the Sawyer Spindle Company, of Maine, a Corporation of Maine. Filed Feb. 27, 1897. Serial No. 626,266. (No model.)

Claim.—1. The combination with a bolster-case provided with an aperture in its base, of a tapered spindle, a bolster forming a bearing for the spindle located within the case, said bolster being loosely supported in the case and provided with an interiorly-smooth aperture in its bottom, a step-pintle for the spindle located in the aperture in the bottom of the bolster-case and projected through the aperture in the bottom of the bolster and free to have direct vertical movements in said apertures, and a support for the step-pintle independent of the support for the bolster adjustable through the base of the bolster-case, substantially as described.



2. The combination with a bolster loosely supported in the bolster-case and bolster having apertures in their bases of a step-pintle free to tip laterally in all directions projecting into the aperture in the base of the bolster, and a support for said step-pintle independent of the support for the bolster adjustable through the base of the bolster-case, substantially as described.

3. The combination with the bolster-case and bolster, of a step-pintle projected into the bolster, and a tubular support for the bolster within the bolster-case loosely surrounding the step-pintle, substantially as described.

4. The combination with the bolster-case and bolster, of a step-pintle projected into the bolster, and a tubular support for the bolster comprising a rocker-washer having a convex face loosely surrounding the step-pintle, substantially as described.

5. The combination with a bolster-case and bolster, of a step-pintle projected into the bolster, a tubular support for the bolster loosely surrounding the step-pintle and a projection on the step-pintle arranged to engage the tubular support to remove said support from the bolster-case, substantially as described.

6. The combination with the bolster-case and bolster, having a circular aperture in its base, a step-pintle projected into said aperture and free to rotate therein, a bolster-support loosely surrounding said step-pintle and restrained from rotation thereby, and connections between the bolster and said support, whereby the bolster is restrained from rotation, substantially as described.

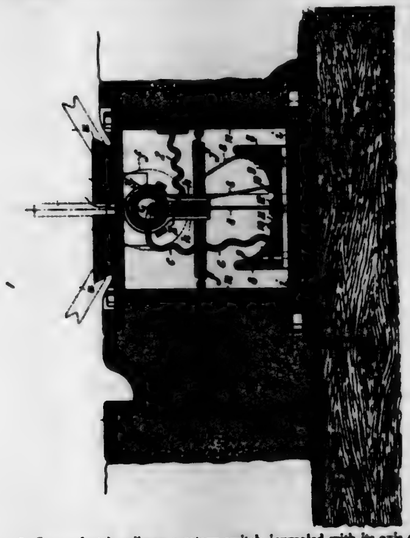
7. The combination with the bolster-case and bolster provided with a polygonal aperture in its base, of a step-pintle polygonal in section adjacent its opposite ends, an adjustable support for the step-pintle having a polygonal aperture therein, said step-pintle engaging at its opposite ends the apertures in the bolster and the adjustable support, substantially as described.

8. In a spindle-bearing, the combination with a bolster-case and bolster, of a step-pintle having a polygonal end engaging a polygonal bearing in the bolster and fitted for a longitudinal movement in the bottom of the bolster-case, means projecting from the bolster-case engaging the step-pintle to turn the same, and an intermediate annular bearing between the lower end of the bolster and the bolster-case, substantially as described.

705,848. ELECTRIC RAILWAY. CHARLES J. KINTNER, New York, N. Y. Filed Oct. 20, 1900. Renewed Feb. 20, 1902. Serial No. 94,128. (No model.)

Claim.—1. In an electric railway a switch journaled with its axis of rotation substantially parallel with the track-rails and provided with means for adapting it to be rotated gradually and continuously about its axis of rotation as a car passes over or by it, substantially as described.

2. In an electric railway a rotary switch journaled with its axis of rotation substantially parallel with the track-rails and provided with a spiral thread or groove in the direction of its length and of such pitch as to be given a gradual rotation as a car passes over or by it, substantially as described.



3. In an electric railway a rotary switch journaled with its axis of rotation substantially parallel with the track-rails and provided with means for adapting it to be gradually and continuously rotated about its axis of rotation as a car passes over or by it; in combination with a movable circuit making and breaking terminal adapted to be operated thereby, substantially as described.

4. In an electric railway a current feeder or main extending over the route and a series of third rails or sectional conductors normally disconnected therefrom; in combination with a series of rotary switches journaled with their axes of rotation substantially parallel with the track-rails and provided with means for giving them gradual and continuous rotation about their axes as a car travels over or by them; together with circuit connections whereby said third rails or sectional conductors are electrically connected to and disconnected from the current feeder or main in sequence and without damaging mechanical effects, substantially as described.

5. In an electric railway a series of rotary tubular switches inclosing a current feeder or main and constituting a conduit therefor, substantially as described.

6. In an electric railway a series of rotary tubular switches journaled in alinement with each other and constituting a means for conveying a heating medium for effecting better insulation and avoiding the evil effects of accumulated snow or ice, substantially as described.

7. In an electric railway a series of rotary tubular switches journaled in alinement with each other and with intervening switch-boxes inclosing circuits and circuit connections, the arrangement being such that a heating medium, as dry air, may be admitted through the tubular switches to the boxes, better insulation effected, and the system protected from evil effects of snow and ice, substantially as described.

8. In an electric railway a series of rotary switches journaled in alinement with each other and with their axes of rotation substantially parallel with the track-rails; in combination with a switch-actuating trolley adapted to impart gradual and continuous rotary movement to said switches, and means for maintaining said trolley always in a fixed relation to the switches, substantially as described.

9. In an electric railway a series of rotary switches journaled with their axes of rotation substantially parallel with the track-rails and operatively connected with circuits and circuit connections running to conducting third rails or conductors and a current feeder or main; in combination with a switch-actuating trolley having one or more mechanical trolley-rollers for controlling the movement of the switches; guide-rollers together with guiding means therefor adapted to maintain the trolley always in a fixed relation to the switches, substantially as described.

10. In an electric railway a series of rotary switches journaled with their opposite ends in adjoining switch-boxes and provided each with means for giving rotary motion thereto as a car passes over them; in combination with movable circuit making and breaking terminals operated by said switches, substantially as described.

11. In an electric railway a rotary switch journaled with its axis of rotation parallel with the tram-rails and provided with a spiral thread or groove in the direction of its length; in combination with means for yieldingly holding said switch and groove in a definite position, substantially as described.

12. In an electric railway, embracing a current feeder or main and sectional third rails or conductors, a series of rotary switches having their axes of rotation parallel with the tram-rails, said switches being provided each with a spiral thread or groove in the direction of its length; in combination with yielding means adapted to hold each of said switches with its thread or groove in a definite position; together with movable circuit making and breaking terminals operated by the switches and adapted to connect the third rails or conductors to and disconnect them from the current feeder or main, substantially as described.

13. In an electric railway a series of rotary switches having their axes of rotation parallel with the tram-rails, said switches being provided with means for rotating them as a car or vehicle passes thereover; in combination with ball-supporting bearings and means for yieldingly holding the switches in definite positions; together with movable circuit making and breaking terminals controlled thereby, substantially as described.

14. In an electric railway a series of rotary switches provided each with a spiral thread or groove extending in the direction of its length; in combination with a conduit inclosing said switches and having a guiding trolley-slot located above the thread or groove, substantially as described.

15. In an electric railway a series of rotary switches provided each with a spiral groove in the direction of its length; in combination with a conduit surrounding the same, said conduit having a slot bearing a definite or fixed relation to the grooves; together with a switch-actuating trolley adapted to always maintain a fixed relation to the grooves and the slot, substantially as described.

16. In an electric railway a series of rotary switches having their opposite ends journaled in adjoining switch-boxes, said switches being each provided with a spiral groove in the direction of its length; in combination with a conduit surrounding and supporting the switches and provided with a slot having a definite relation to the grooves; together with removable switch-box covers provided each with a slot located, when in position on the boxes, in alinement with the conduit-slot, substantially as described.

17. In an electric railway a series of rotary switches having their opposite ends journaled in adjoining switch-boxes, said switches being each provided with a spiral groove in the direction of its length; a conduit surrounding and supporting the switches and provided with a slot having a definite relation to the grooves; in combination with removable switch-box covers provided each with a slot located, when in position on the boxes, in alinement with the conduit-slot; together with a switch-actuating trolley so constructed and arranged with relation to the conduit and the switches that it always maintains a definite or fixed relation thereto, substantially as described.

18. In an electric railway a series of tubular rotary switches journaled with their opposite ends in adjoining switch-boxes and provided each with means for giving rotary motion thereto as a car passes over them; in combination with movable circuit making and breaking terminals operated by said switches and a current feeder or main inclosed within said tubular switches, said current feeder or main being composed of sectional parts having their opposite ends secured in the switch-boxes and so arranged that any section of the feeder may be removed and repaired or replaced without disturbing the other sections thereof, substantially as described.

19. In a sectional contact system for electrical railways, successive rotary, contact-sections extending longitudinally of the line of way and having each a spiral path extending longitudinally thereof, means for supplying current to the sections and cutting it off therefrom, and a device carried by the car for following the spiral paths and rotating said sections.

20. In a sectional contact system for electrical railways, a longitudinal rotary contact-section provided with a spiral web extending lengthwise thereof, means for supplying current thereto, and means carried by the car for engaging said web to rotate said section and take current therefrom.

21. In a sectional contact system for electrical railways, longitudinal rotary contact-sections arranged in succession along the line of way having spirally-arranged projections by which to rotate them, and circuit-controlling switches operated by the rotation of the sections.

22. In a sectional contact system for electrical railways, longitudinal rotary contact-sections arranged in succession along the line of way each having a spiral path extending along it, and circuit-controlling switches operated by said section in combination with means carried by the car and adapted to travel said spiral paths for rotating the sections and taking current therefrom.

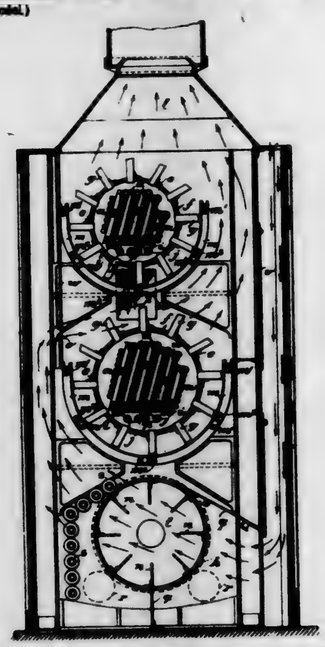
23. In a sectional contact system for electrical railways, the combination with a conduit along the line of way, of rotary switches located

therein for each section and provided with spiral projections and means carried by the car for entering said conduit and engaging said projections for rotating said switches, for the purpose set forth.

24. In a sectional contact system for electrical railways, the combination of the conduit in insulated sections, a rotary contact-section journaled in each section of conduit, means for supplying current to each section, and a current-collector carried by the car for engaging the rotary sections successively.

25. In a sectional contact system for electrical railways, rotary contact-sections extending along the line of way and provided with spiral paths extending longitudinally thereof, means for feeding current to said sections successively, and a current-collector carried by the car and following said spiral paths, for the purpose specified.

705,849. **APPARATUS FOR DRYING GRAIN, &c.** MAX KÖNIG, Grosslichterfelde, Germany. Filed Mar. 14, 1900. Serial No. 8,625. (No model.)



Claim.—1. In a drying apparatus for drying grain and other materials, the combination of a trough for receiving the materials, an agitator provided with an internal stationary heater, consisting of separate inclined sections, and adjustable baffle-plates or strips located between the heater-sections, essentially as and for the purpose described.

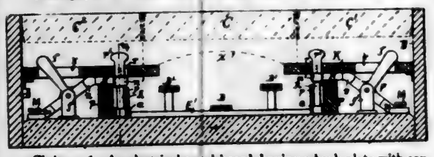
2. In a drying apparatus for drying grain and other materials, the combination of a trough for receiving the materials, an agitator provided with an internal stationary heater consisting of separate inclined sections, baffle-plates located between the heater-sections, and means for adjusting the baffle-plates into forwardly and rearwardly inclined positions, essentially as and for the purpose described.

3. In a drying apparatus for drying grain and other materials, the combination of a trough for receiving the materials, an agitator provided with an internal stationary heater consisting of separate inclined sections, and pivotally-suspended baffle-plates, finger-pieces bearing against the said baffle-plates, and means for moving said finger-pieces in forward or rearward direction for adjusting the baffle-plates into forwardly and rearwardly inclined positions, essentially as and for the purpose described.

4. In a drying apparatus for drying grain and other materials the combination of a trough for receiving the materials, an agitator provided with an internal stationary heater consisting of separate inclined sections, pivotally-suspended baffle-plates located between the heater-sections, finger-pieces bearing against said baffle-plates for adjusting the baffle-plates into forwardly and rearwardly inclined positions, and draw-bars projecting through the end of the trough for moving said finger-pieces from the outside of the apparatus, essentially as and for the purpose described.

5. In a drying apparatus for drying grain and other materials, the combination of a trough for receiving the materials, an agitator provided with a heater, adjustable baffle-plates, a perforated drum having internal scoops and located underneath the trough, air-passages, and guide-plates for conducting a ventilating air-current through the drum and farther on through the heating portion of the apparatus into the chimney, essentially as and for the purpose described.

705,850. **ELECTRICAL PANEL-BOARD.** HUBERT KRANTZ, Brooklyn, N. Y. Filed Mar. 12, 1902. Serial No. 97,871. (No model.)



Claim.—1. An electrical panel-board, having a back plate with conducting-bars and switches mounted on the said back plate, and a protecting-cover inclosing the said conducting-bars and the current-carrying parts of the switches and their connections, said cover having openings for the manipulation of the switches.

2. An electrical panel-board, having conducting-bars, switches and fuses and contacts for the switches and fuses, with a protecting-cover inclosing the said conducting-bars, switches and fuses and their contacts, said cover having openings for the insertion of the fuses and for the manipulation of the switches.

3. An electrical panel-board, having a back plate, bus-bars and cross-bars with branch circuit connections and switches therein, all mounted on said back plate, and a protecting-cover inclosing all the current-carrying parts of the panel-board but with openings for the manipulation of the switches.

4. An electrical panel-board, having a back plate, bus-bars and cross-bars with branch circuit connections and switches and fuses in said branch circuits and a protecting-cover for all the current-carrying parts of the panel-board, but with openings for the insertion of the fuses and the manipulation of the switches, substantially as described.

5. An electrical panel-board having a back plate and conducting-bars and switches thereon with pairs of fuse-clips, one clip of each pair being in front of the other to receive the fuse-cartridge substantially at right angles to the plane of the back plate, in combination with a protecting-cover for all the current-carrying parts of the panel-board, but with openings for the insertion of the fuses and the manipulation of the switches, substantially as described.

6. An electrical panel-board, having a back plate and conducting-bars, switches and connecting-plates with pairs of fuse-clips, one clip of each pair being directly on the back plate and the other over or in front of the first to receive the fuse-cartridge substantially at right angles to the plane of the back plate, in combination with a protecting-cover for all the current-carrying parts of the panel-board, but with openings for the insertion of the fuses and the manipulation of the switches, substantially as described.

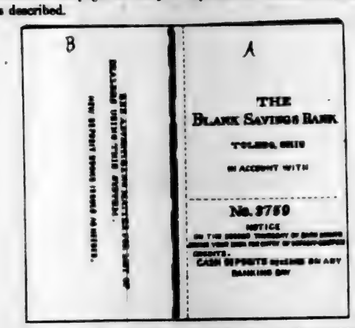
7. An electrical panel-board having a back plate and conducting-bars with pairs of fuse-clips, one clip of each pair being over or in front of the other and a cover-plate for the fuse-clips, said cover-plate having a hole for the insertion of the fuse-cartridge substantially at right angles to the back plate.

8. An electrical panel-board having a back plate and conducting-bars with binding-posts having contacts on the back plate, and contact-plates at some distance from the face of the back plate, a switch having a pivoted current-carrying part to make connection with said contacts and a cover-plate with a hole through which the switch can be manipulated.

705,851. **BANK-DEPOSIT-COUPON BOOK.** PAUL KUHER, Toledo Ohio, assignor to Harry Hoyle and Caroline Kuhen, Toledo, Ohio. Filed Mar. 21, 1902. Serial No. 99,231. (No model.)

Claim.—1. A numbered book for banking and commercial purposes, said book consisting of a set of covers with a number on one of said covers, a number of leaves provided with appropriate headings and ruled and arranged with columns so as to constitute a debit and credit page for deposits and withdrawals, and a desired number of leaves perforated so as to form stubs with detachable coupons interposed between said covers, said coupons bearing a number identical with that on cover and having printed thereon an agreement that the person detaching such coupon will deposit it in a certain bank, substantially as described.

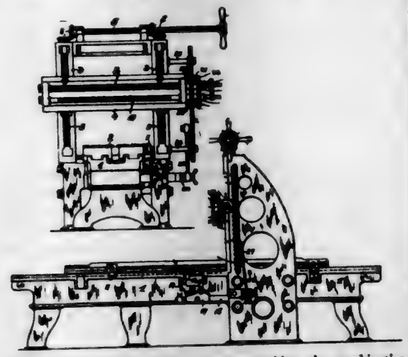
2. In a book for banking and commercial purposes, the combination, with a set of covers, one of said covers having a number thereon, of a series of sheets being divided by horizontal and vertical rows of perforated and unperforated lines into coupons and stubs, said coupons bearing a number identical with number on cover and each having printed thereon an agreement that the person detaching such coupon will deposit it in a certain bank together with amount in money represented thereby, said stubs bearing a number the same as number on coupons and each having printed thereon a form of receipt, and a series of sheets having appropriate headings and horizontal and vertical lines arranged to constitute debit and credit pages for entry of deposits and withdrawals, substantially as described.



3. In a book for banking and commercial purposes, the combination, with a set of covers having a number thereon and a series of sheets having headings and vertical columns for debit and credit entries, of a series of sheets, said sheets being divided by horizontal and vertical perforated lines into detachable coupons and stubs therefor, each of said coupons and stubs bearing a number identical with number on cover, said coupons containing an agreement that the person detaching them agrees to deposit an amount represented thereby in the bank designated on said cover, and the stubs each containing a blank form of agreement to be signed by person detaching said coupons.

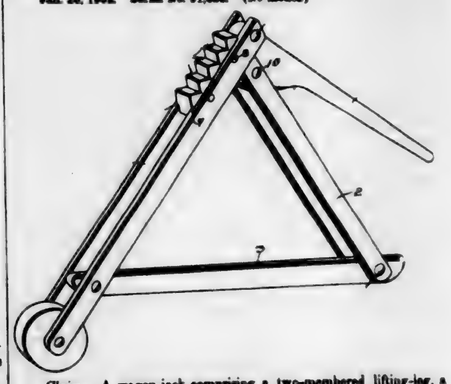
4. The combination, with a book having a numbered cover and leaves with headings and columns for debit and credit entries, of other leaves comprising discount deposit-coupons containing an agreement that the person detaching the same will deposit an amount named thereon to credit of person designated, and stubs therefor containing a form of agreement, said coupons being adapted to be detached from said stubs, and the said stubs and coupons being numbered to correspond to number on said cover, all being assembled and bound together, substantially as described.

705,852. **DOUBLE-WORKING PLANING-MACHINE.** JACOB LEHMANN and HERMANN MAURER, Bockenheim, Germany. Filed Mar. 4, 1902. Serial No. 96,712. (No model.)



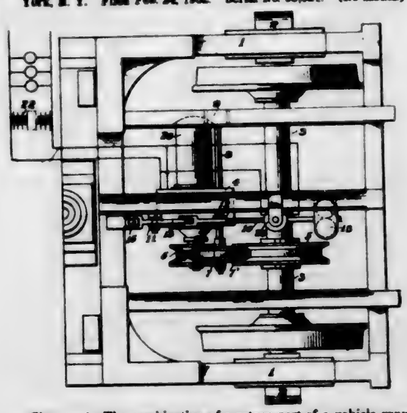
Claim.—In a double-working planing-machine, the combination with the bed and table, the frame for vertically guiding the cross-rail and said cross-rail, of a horizontal feed-screw spindle in said cross-rail, a grooved spindle in said latter parallel to said screw-spindle, guides extending from said frame, a rack-bar vertically movable up or down on said guides and means on the table to so move it at each end of the stroke of the table, a gear-wheel mounted on said cross-rail and meshing with said rack-bar, two toothed wheels in gear with said gear and loosely mounted on said spindles respectively, a ratchet-wheel rigidly fastened on said grooved spindle adjacent to said toothed wheel, another ratchet-wheel loosely mounted on said screw-spindle, a clutch on said screw-spindle adapted to engage its ratchet-wheel so as to connect the same to the spindle, arms in rigid connection with said toothed wheels and pawls carried on said arms for engaging said ratchet-wheels in either direction, substantially as described.

705,853. **WAGON-JACK.** JONAS D. MACK, Salem, N. Y. Filed Jan. 25, 1902. Serial No. 91,623. (No model.)



Claim.—A wagon-jack comprising a two-membered lifting-leg, a two-membered fulcrum-leg, a step-plate secured between the upper terminals of the members of the lifting-leg and serving to hold the same properly spaced apart, a base-bar pivotally secured between the lower terminals of the lifting-leg, and the fulcrum-leg, a wheel or roller carried by the lifting-leg, and a lever pivotally connected between the upper terminal of the lifting-leg and the fulcrum-leg, substantially as and for the purpose specified.

705,854. **GENERATING APPARATUS FOR CAR-LIGHTING.** ALBERT P. MADDEN, Newark, N. J., assignor to Charles A. Gould, New York, N. Y. Filed Feb. 24, 1902. Serial No. 95,321. (No model.)



Claim.—1. The combination of a rotary part of a vehicle running-gear, a friction-wheel mounted thereon, a dynamo flexibly and independently mounted with respect to the running-gear, a friction-wheel on the dynamo-shaft, a transmitting-wheel engaging the wheels on the running-gear and dynamo-shaft, said transmitting-wheel mounted to swing in an arc which intersects the peripheries of both the said wheels.

2. The combination of a rotary part of a vehicle running-gear, a friction-wheel mounted thereon, a dynamo flexibly and independently mounted with respect to the running-gear, a friction-wheel on the dynamo-shaft, a transmitting-wheel engaging the wheels on the running-gear and dynamo, the tangential lines of contact between the several wheels being inclined to one another at an angle not less than a right angle.

3. The combination of a rotary part of a vehicle running-gear, a friction-wheel mounted thereon, a dynamo flexibly and independently mounted with respect to the running-gear, a friction-wheel on the dyna-

mo-shaft, a transmitting-wheel engaging the wheels on the running-gear and dynamo-shaft and mounted in the free end of a swinging link, said link connected to a lever flexibly mounted on the vehicle-frame.

4. The combination of a rotary part of a vehicle running-gear, a friction-wheel mounted thereon, a dynamo flexibly and independently mounted with respect to the running-gear, a friction-wheel on the dynamo-shaft, a transmitting-wheel engaging the wheels on the running-gear and dynamo-shaft and mounted in the free end of a swinging link, said link connected to a lever flexibly and adjustably mounted on the vehicle-frame.

5. The combination of a rotary part of a vehicle running-gear, a friction-wheel mounted thereon, a dynamo flexibly and independently mounted with respect to the running-gear, a friction-wheel on the dynamo-shaft, a transmitting-wheel engaging the wheels on the running-gear and dynamo-shaft and mounted in the free end of a swinging link, said link connected to a lever flexibly mounted on the vehicle-frame, said lever having spring connection at one end with the vehicle-frame and connected at its other end with adjusting means to adjust the pressure of the said transmitting-wheel on the friction-wheels of the dynamo and vehicle running-gear.

6. The combination of a rotary part of a vehicle running-gear, a friction-wheel mounted thereon, a dynamo flexibly and independently mounted with respect to the running-gear, a friction-wheel on the dynamo-shaft, a screw-threaded rod mounted on the vehicle-frame, a block engaging said rod, a link pivoted on the vehicle-frame, one end of said link connected to said block, a spring-pressed lever having one end connected to said pivoted link and the other end having a spring connection with the vehicle-frame, a swinging arm supported at one end from said lever intermediate its ends and carrying at its other end a transmitting-wheel to engage the friction-wheels on the dynamo-shaft and the vehicle running-gear.

7. The combination of a rotary part of a vehicle running-gear, a friction-wheel mounted thereon, a dynamo flexibly and independently mounted with respect to the running-gear, a friction-wheel on the dynamo-shaft, a transmitting-wheel engaging the wheels on the running-gear and dynamo-shaft and mounted in the free end of a swinging link, said link connected to a lever flexibly mounted on the vehicle-frame, said lever having spring connection at one end with the vehicle-frame and connected at its other end with adjusting means, and having connected therewith an electrical device energized from the dynamo to control the pressure of the transmitting-wheel upon the friction means.

8. The combination of a rotary part of a vehicle running-gear, a friction-wheel mounted thereon, a dynamo flexibly and independently mounted with respect to the running-gear, a friction-wheel on the dynamo-shaft, a transmitting-wheel engaging the wheels on the running-gear and dynamo-shaft, said transmitting-wheel being free to swing toward one of said friction-wheels and from the other, but to maintain contact with both of said friction-wheels.

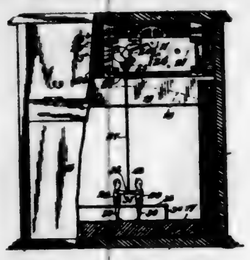
9. The combination of a rotary part of a vehicle running-gear, a friction-wheel mounted thereon, a dynamo flexibly and independently mounted with respect to the running-gear, a friction-wheel on the dynamo-shaft, a transmitting-wheel flexibly supported from the vehicle-frame and engaging the said friction-wheels, said transmitting-wheel being free to move in a direction from one of said friction-wheels toward the other while maintaining contact with both of said friction-wheels.

10. The combination of a rotary part of a vehicle running-gear, a friction-wheel mounted thereon, a dynamo flexibly and independently mounted with respect to the running-gear, a friction-wheel on the dynamo-shaft, a transmitting-wheel flexibly supported from the vehicle-frame and engaging the said friction-wheels, said transmitting-wheel being free to move in a direction from one of said friction-wheels toward the other while maintaining contact with both of said friction-wheels, means to adjust the pressure of said transmitting-wheel upon the friction-wheels.

11. The combination of a rotary part of a vehicle running-gear, a friction-wheel mounted thereon, a dynamo flexibly and independently mounted with respect to the running-gear, a friction-wheel on the dynamo-shaft, a transmitting-wheel flexibly supported from the vehicle-frame and engaging the said friction-wheels, said transmitting-wheel being free to move in a direction from one of said friction-wheels toward the other while maintaining contact with both of said friction-wheels, means operated from the interior of the vehicle to adjust the pressure of said transmitting-wheel upon the friction-wheels.

705,855. TOY OR ADVERTISING DEVICE. JOHN A. MANGOLD, Moundsville, W. Va. Filed June 20, 1901. Serial No. 65,332. (No model.)

Claim.—1. In a device of the class described, the combination with a platform, of a motor having a driven shaft, a portion of said shaft being located above the platform, and a freely-swinging puppet suspended from and having an eccentric connection with the portion of the shaft that is located above the platform, whereby said puppet is moved laterally as well as vertically upon the movement of the shaft.



2. In a device of the class described, the combination with a platform, of a motor having a driven shaft, a portion of said shaft being located above the platform, and a freely-swinging puppet suspended from and having an adjustable eccentric connection with the portion of the shaft that is located above the platform, whereby said puppet is moved laterally as well as vertically upon the movement of the shaft and the range of movement of said puppet may be varied.

3. In a device of the class described, the combination with a platform, of a motor having a driven shaft, a portion of said shaft being located above the platform, a freely-swinging puppet located above the platform, and a flexible connection secured at one end to the puppet and having its other end eccentrically attached to the portion of the shaft that is arranged above the platform, to move the puppet laterally as well as vertically upon the rotation of said shaft.

4. In a toy of the class described, the combination with a driven shaft, of means for driving the shaft, a puppet, and a connection attached at one end to the puppet and its other end having a detachable eccentric connection with the shaft, said connection being movable toward and from said shaft, whereby the range of movement of the puppet may be varied.

5. In a toy of the class described, the combination with a driven shaft, of means for driving the same, a body having an adjustable eccentric connection with the shaft at one side, and a counterweight adjustably secured to the shaft on the side opposite the puppet connection.

6. In a toy of the class described, the combination of a driven shaft, of means for driving the same, a disk secured to the shaft and rotatable therewith, a puppet adjustably connected to the disk on one side of the shaft, and a counterweight adjustably secured to the disk on the side opposite the puppet connection.

7. In a toy of the class described, the combination with a driven shaft, of means for driving the same, a disk secured to the shaft and rotatable therewith, said disk being provided on one side with a row of openings extending from the shaft toward the rim, and a slot located in alinement with the row of openings on the opposite side of the shaft, a puppet, a connection between the puppet and the disk, said connection including a hook detachably engaging in the openings of the disk, a counterweight located on the side of the disk opposite the hook, and a set-screw passing through the slot of said disk and engaging the counterweight.

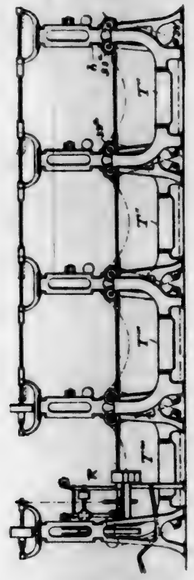
705,856. APPARATUS FOR DYEING, &c. DIEGO MATTEI, Genoa, Italy. Filed Aug. 17, 1897. Serial No. 648,598. (No model.)

Claim.—1. In combination, the guides for the sliver, a bath through which the sliver is passed and a device having a steam and a liquid jet arranged to act on the said sliver before the same enters the bath, substantially as described.

2. In combination, a bath, means for directing the sliver thereto and a moistening-jet device arranged adjacent to the path of the sliver, said jet device being supported to move toward the sliver by gravity, substantially as described.

3. In combination, the carrier-belts for the sliver, the bath, the guide over which the sliver passes, a box 25 having a discharge-opening directed toward the belt and below the same, and a box 29 arranged above the belt and having two compartments one for steam and one for water with discharge-openings in each directed toward the sliver on the belt, substantially as described.

4. In combination, a series of tanks, means for passing the sliver through the tanks comprising endless belts, carrier means for conveying the sliver from one endless belt of one tank to that of the next tank, said carrier means including a pair of endless belts to receive the sliver between them and means for arranging the sliver in folds between the said belts, said means comprising the reel and the movable plate 31 and operating means therefor, substantially as described.



705,857. CURTAIN-STRETCHER. WALTER A. MAYR, Chicago, Ill. Filed Nov. 16, 1901. Serial No. 82,569. (No model.)

Claim.—1. In a curtain-stretcher, a center brace, side bars pivotally connected with each end thereof, said side bars being jointed and adapted to fold in the same plane upon said brace while retained in pivotal connection with each end thereof, one of said side bars being longitudinally adjustable on said brace, as and for the purpose set forth.

2. In a curtain-stretcher, a center brace, a plate secured to one end thereof, a plate adjustably secured to the other end of said brace, and jointed side bars pivotally connected with said plates respectively and both retained in pivotal connection in an extended and folded position for the purpose set forth.

3. In a curtain-stretcher, a center brace slotted at one end, a plate secured to the unslotted end, a plate adjustably secured to the slotted end by a bolt and winged nut, and jointed side bars pivotally connected with said plates and both retained in pivotal connection in an extended and folded position, as and for the purpose set forth.

4. In a curtain-stretcher, a center brace slotted at one end, a plate secured to the unslotted end, a plate adjustably secured to the slotted end by a bolt and winged nut, and jointed side bars connected with said plates and adapted to fold in the same plane with the parts connected with the adjustable plate outside the other parts, as and for the purpose set forth.

5. In a curtain-stretcher, a center brace, a plate connected with each end thereof, jointed side bars pivotally connected with said plates and both retained in pivotal connection in an extended and folded position, said side bars having rounded inner corners and flat ends, as and for the purpose set forth.

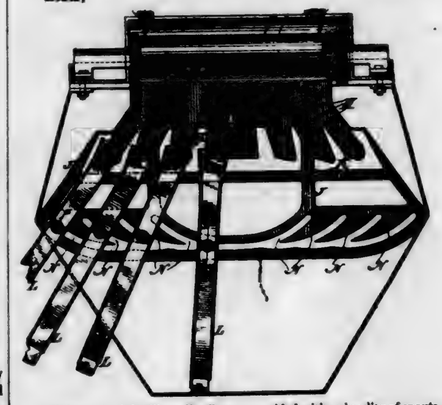
6. In a curtain-stretcher, a center brace, a plate adjustably secured to one end thereof, a plate secured to the other end thereof, a side bar composed of two pieces pivotally connected with each of said plates and both retained in pivotal connection in an extended and folded position, the abutting ends of said pieces having rounded inner corners and flat ends, as and for the purpose set forth.

7. In a curtain-stretcher, the combination of two end bars, two side bars each of which is composed of two pieces, plates with which said pieces are pivotally connected, a center brace, said plates being secured to said brace, the pivotal connection between said pieces and said plates being so proportioned and disposed that the pieces composing one of said bars may be folded in the same plane outside of the pieces of the other bar in a folded position, while in pivotal connection with the respective plate, as and for the purpose set forth.

8. A curtain-stretcher comprising a center brace, a plate secured to one end thereof, a side bar composed of two pieces pivotally connected with said plate, said pieces having rounded inner corners and flat ends, a plate adjustably secured to the other end of said brace, a side bar composed of two pieces pivotally connected with said last plate, said last pieces having rounded inner corners and flat ends, the pivotal connection with said last plate being at a greater distance from the center brace than said first pieces, and end bars adjustably connected with the ends of said pieces as and for the purpose set forth.

9. The combination in a curtain-stretcher of two end bars, two side bars each of which is composed of two pieces, a center brace-bar pivotally connected with said side bars at each end, and both retained in pivotal connection in an extended and folded position, each of the two pieces composing said side bars having rounded corners whereby they may be folded inward upon said center brace-bar, as and for the purpose set forth.

705,858. FERTILIZER-DISTRIBUTER. ALLEN MCWHORTER, Norfolk, Va., assignor to McWhorter Manufacturing Company, a Corporation of New Jersey. Filed Jan. 13, 1902. Serial No. 89,489. (No model.)



Claim.—1. A fertilizer-distributer, provided with a plurality of spouts, said spouts being independently movable transversely to the length of the machine.

2. A fertilizer-distributer, having a plurality of channels leading from the hopper, and spouts at the lower ends of said channels movable transversely to the length of the machine.

3. A fertilizer-distributer, having a plurality of channels leading from the hopper, spouts pivoted at the lower end of said channels, and means for holding said spouts in adjusted positions.

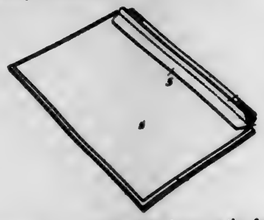
4. A fertilizer-distributer, having a plurality of channels leading from the hopper, spouts pivoted independently at the lower end of said channels, a frame upon which said spouts are supported, and friction devices carried by the spouts and engaging said frame.

5. A fertilizer-distributer, having a plurality of channels leading from the hopper, spouts pivoted at the lower end of said channels, a frame extending below said channels and in the rear of said spout, guide-slots in said frame, pins carried by said spouts extending through said guide-slots, and friction devices mounted upon said pins and engaging said frame.

705,859. BOOK-COVER. CARL HEUENDORFFER, New York, and BERTHA WITTER, Brooklyn, N. Y. Filed Oct. 23, 1901. Serial No. 79,608. (No model.)

Claim.—1. As a new article of manufacture, a binding for paper books and the like, consisting of a front and back having means for flexibly uniting them together, and fabric binders for the front and back each composed of a plurality of united leaves one of which is secured between the cover part and the inner finishing-sheet, another of which is adapted to be secured to a fly-leaf and the other two of which are adapted to be

secured to the outer side and the back of the body of the book in the manner substantially as described.

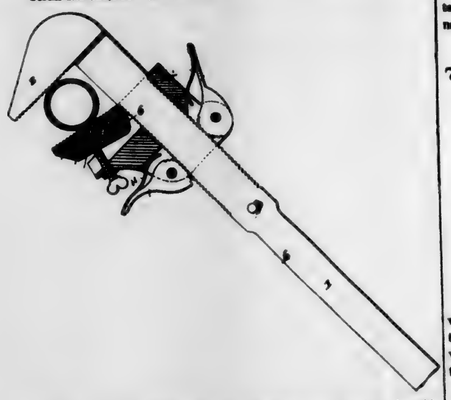


2. A book having a plurality of its leaves at the front and back gummed to form solid parts, a fabric binder at each inner edge of the book-body, said binders being each composed of a plurality of united leaves a pair of which are secured to an inner edge of the book-body, and a cover consisting of a front and back the front of which has a flap extension for securing the cover parts together, and each cover part having an inner finishing-sheet between which and the cover part another leaf of the binder is secured.

3. In combination with a paper-bound book, a front and a back stiff cover part each having a separate gummed fabric-binder strip along its inner edge, and a gummed flap extending from the front cover along the fabric binder, the said binders uniting the covers to the book at its back edges and the gummed flap uniting the cover parts, covering the binders and forming a binder for the back.

4. In combination with a paper-bound book having a plurality of its leaves gummed together to form a foundation extending from the bound back on each side of the book, a front and a back cover part each having a separate fabric-binder strip fastened to said foundation parts and the front cover part having a gummed flap for covering the binders, uniting the covers and forming a binding for the back.

705,860. WRENCH. JOSEPH O'BRIEN, Brooklyn, N. Y., assignor of one-half to Avery H. Bettling, New York, N. Y. Filed June 5, 1902. Serial No. 110,344. (No model.)

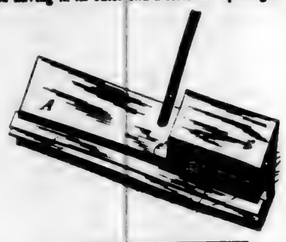


Claim.—1. In a wrench and in combination, the jaw-bar, the slidable head having an integral bottom wall standing at right angles to the edge of the jaw-bar, means for clamping the head to the bar, a grip-jaw pivoted to the head in overhanging relation to the bottom wall, a plate-spring on the jaw between it and said bottom wall, and a drive-screw tapped in said bottom wall beneath said spring.

2. In a wrench and in combination, the jaw-bar, the slidable head having an integral bottom wall standing at right angles to the edge of the jaw-bar, means for clamping the head to the bar, a grip-jaw pivoted at the inner corner of its inner end to the head, and a drive-screw tapped in the bottom wall beneath the grip-jaw to drive the latter against the pipe and by such driving force cause the outer corner of the jaw to be forced with a clamping action against the bar to reinforce the means for clamping the head to the bar.

705,861. SPRINKLING SCRUB-BRUSH. FELIX PIERSON, Ravenswood, Ill. Filed Mar. 21, 1902. Serial No. 99,303. (No model.)

Claim.—In a sprinkling scrub-brush, the combination with a block or body having in one of its ends cavities provided with a series of openings, a door or valve hinged to the upper surface of the block to close said cavities, and a box secured to the block or body over the cavities therein and having in its outer end a series of openings, substantially as described.

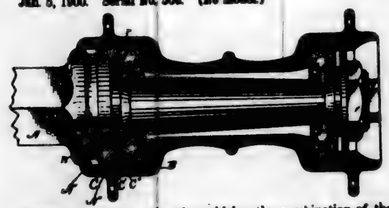


705,862. GAS-BURNER. SIMON A. POLITZKY and JOSEPH AGUST, Boston, Mass. Filed Nov. 2, 1901. Serial No. 80,679. (No model.)

Claim.—1. A gas-burner comprising an inner initial mixing-tube having an air-inlet and a discharge-orifice, a gas-discharge outlet directed into said tube in the vicinity of the air-inlet, and an outer secondary mixing-tube surrounding the discharge-orifice of the first said tube and having a burner-orifice, said secondary tube having its lower end removably fitting the exterior of the inner tube above the air-inlet of the latter and having its walls above its lower end expanded and forming alternate arms and air-inlets.

2. A gas-burner comprising a plurality of inner initial mixing-tubes having air-inlets and discharge-orifices, gas-discharge outlets directed into said tubes in the vicinity of the air-inlets, and a single outer secondary mixing-tube surrounding the discharge-orifices of the first said tubes and having a burner-orifice, said secondary tube having its lower end removably fitting the exterior of the inner tubes above the air-inlet of the latter and having its walls above its lower end expanded and forming alternate arms and air-inlets.

705,868. BEARING. HENRY H. PORTER, Dowagiac, Mich. Filed Jan. 5, 1900. Serial No. 508. (No model.)



Claim.—1. In a bearing for vehicles, the combination of the axle with a suitable collar having a flange; a hub or boxing; a dust and water band combined with a ring to fit within the hub, the said dust and water band having an outwardly-projecting V-shaped portion fitting into the flange of the axle, for the purpose specified.

2. In a bearing for vehicles, the combination of the axle with a suitable collar having a flange; a hub or boxing; a dust and water excluder consisting of a band and an outwardly-projecting V-shaped portion carried by said hub or boxing and fitting within the flange of the axle, for the purpose specified.

3. The combination of a dust and water band having an outwardly-projecting V-shaped portion and means of supporting the same within the hub of a wheel.

4. A dust and water band or ring having a V-shaped projection and a retainer-ring open at one side and connected to said dust and water band or ring by a small web, all formed of a single integral piece, for the purpose specified.

5. A dust and water band or ring having a V-shaped projection C and a ring portion C'; and a ring C'' open at one side at *r* and connecting by a small web *s* to one side of the dust-band all formed of a single piece for the purpose specified.

6. A dust and water band and a retainer band or ring open at one side, and connected by suitable means to said dust and water band, for the purpose specified.

705,864. VEHICLE-AXLE AND AXLE-BOX. HENRY H. PORTER, Dowagiac, Mich. Filed Nov. 6, 1897. Serial No. 658,109. (No model.)

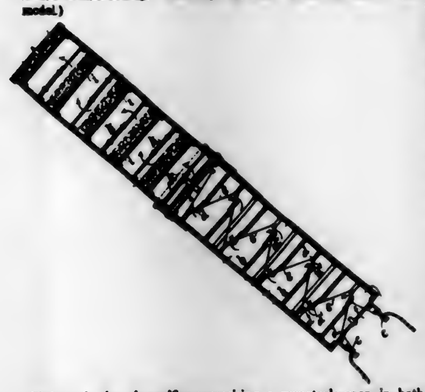
Claim.—1. In a vehicle-axle and axle-box the combination of the spindle A, with the usual or main collar formed thereon with a dirt-groove F, and an additional collar D, of larger diameter with forwardly-projecting cup-shaped flange D', containing dust-groove E, on its outside; the axle-box having formed in connection therewith the rearwardly-projecting outer ring B', adapted to fit over the flange D' on the axle, and having a V-shaped projecting ring C, concentric with ring B', the acute edge of which is adapted to fit the interior of the collar D', leaving an open space within the collar D, on each side of the V-shaped portion; all coacting together substantially as described for the purpose specified.

2. In a vehicle-axle and axle-box the combination of the spindle A, with the usual or main collar formed thereon and an additional collar D, of a larger diameter with a forwardly-projecting cup-shaped flange D'; and an axle-box having formed in connection therewith a rearwardly-projecting ring B', adapted to fit over the flanges D', on the axle and having a V-shaped ring concentric with ring B', the acute angle of which is adapted to fit the interior of the collar D', leaving an open space within the collar on each side of the V-shaped portion, coacting for the purpose specified.

3. In a vehicle-axle and axle-box the combination of the spindle A, with a collar of comparative broad diameter thereon, having a forwardly-projecting cup-shaped flange; and an axle-box having formed in connection therewith a rearwardly-projecting V-shaped ring portion the acute angle of which is adapted to fit within the flange on the axle forming an open space within the flange to each side thereof, coacting for the purpose specified.

4. In a vehicle-axle and axle-box the combination of the spindle A, with the usual or main collar formed thereon and an additional collar D, of a larger diameter with a forwardly-projecting cup-shaped flange D'; and an axle-box having formed in connection therewith a rearwardly-projecting ring B', adapted to fit over the flanges D', on the axle and having a V-shaped ring concentric with ring B', coacting for the purpose specified.

705,865. AIR-PURIFIER. HEINRICH V. PÖCKLER, Schloss Friedland, Silesia, Germany. Filed Sept. 13, 1901. Serial No. 75,204. (No model.)



Claim.—1. An air-purifier comprising a receptacle open in both ends, partitions therein, openings in the partitions in zigzag line, a platinum wire in said zigzag line and a source of current-supply, substantially as described.

2. An air-purifier comprising a receptacle open in both ends, partitions therein, openings in the partitions in zigzag line, a platinum wire in said zigzag line, a source of current-supply and a cup-like vessel below the receptacle, substantially as described.

3. An air-purifier comprising a receptacle open in both ends, partitions therein, openings in the partitions in zigzag line, a platinum wire in said zigzag line, a source of current-supply, a cup-like vessel below the receptacle and a fan above it, substantially as described.

4. An air-purifier comprising a receptacle open at both ends, a platinum wire adapted to carry a current in the lower part and partitions in the upper part, openings in the partitions in zigzag line, and permeable partitions between said first partitions adapted to contain absorbent and filtering material, substantially as described.

5. An air-purifier comprising a receptacle open at both ends, partitions therein, each partition having an opening, said openings arranged in zigzag line, a platinum wire in the zigzag path of the lower portion of the receptacle, a source of current-supply therefor, and permeable partitions in the upper portion, adapted to contain absorbing and filtering materials, substantially as described.

705,866. ADJUSTABLE SCREW-PROPELLER. EDWARD E. PUDNEY, Norwalk, Conn., assignor to HORACE E. DANN and OSCAR H. BANKS, Norwalk, Conn. Filed Dec. 20, 1901. Serial No. 86,672. (No model.)

Claim.—1. An adjustable screw-propeller comprising a hub having threaded bosses, blades having threaded shanks adapted to engage the bosses, set-nuts upon the shanks adapted to engage the bosses to lock the blades when turned forward, and means for locking said shanks against movement in the bosses when the propeller is turned backward.

2. An adjustable screw-propeller comprising a hub having threaded bosses, blades having threaded shanks adapted to engage the bosses, set-nuts upon the shanks adapted to engage the bosses to lock the blades when turned forward and set-screws in the bosses which engage the shanks to lock the blades when turned backward.

705,867. COMBINATION SQUARE AND LEVEL. HARRY H. RICHARDSON, Beaverhills, Pa. Filed Feb. 26, 1902. Serial No. 96,710. (No model.)

Claim.—1. In a square, the combination of the body portion provided with a series of blade-seats the adjacent ones of which are separated by intervening walls, a removable blade, and a single clamp for holding the blade in either of the seats.

2. In a square, the combination of the body portion provided on its opposite sides with blade-seats and a central seat in its upper edge, a removable blade, and a clamp provided in its upper end with a slot, said clamp adapted to engage and retain the said blade when arranged in either of the said seats.

3. In a square the combination of the body portion provided with a central seat in its upper edge, and a seat on each side thereof, said body portion provided with a vertically-arranged opening communicating with the said central seat, a clamp provided with a screw-threaded shank, arranged in the said opening and having its upper end provided with a slot registering with the said longitudinal seat, a screw-threaded sleeve on said shank, a removable blade, and means whereby the said clamp will retain the said blade in each of the said seats.

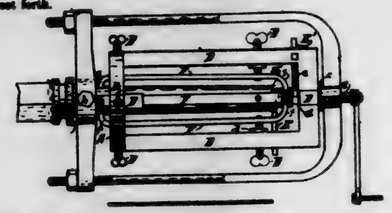
4. In a square, the combination with a body portion provided with a central slot and formed on its opposite sides with shoulders, of a blade formed on one of its sides with a dovetail slot, said blade adapted to be received in the said central slot and shoulders of the body portion, clamping-jaws to engage the said blade and formed with a screw-threaded shank secured in said body portion, said clamping-jaws formed with dovetail extensions on their outer sides and one of them with such extension on its inner side, and a screw-threaded sleeve secured to said screw-threaded shank.

705,868. AXLETREE REPAIR IMPLEMENT. FRANK REHARD, Sandfield, Mich. Filed Apr. 18, 1902. Serial No. 103,636. (No model.)

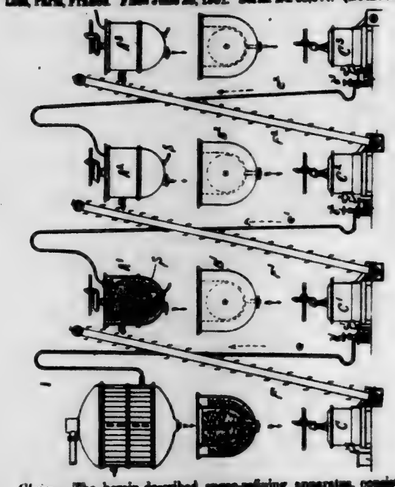
Claim.—1. In an implement for repairing axletrees, an arm adapted to be secured to the axletree, a yoke connected with said arm and projecting back beyond the end of the axletree, a frame within said yoke and having a central bearing through the body of said yoke, adjustable clamps within said frame and arranged to center said frame with the axletree, adjusting-screws passing through the frame and said clamps, cutting-tools supported in said frame and having intermediate supports between the frame and the axletree, substantially as and for the purpose set forth.

2. In an implement for repairing axletrees, an adjusting-yoke adapted to be secured to the axletree, and having a central bearing, a frame having a central bearing engaging the central bearing of the yoke, said

frame extending over the axletree longitudinally, clamps within said frame, adjusting-screws actuating said clamps, a stationary cutter, an adjustable cutter, and a detachable and longitudinally-adjustable cap having an aperture for the cutter, and supporting-ribs, substantially as and for the purpose set forth.

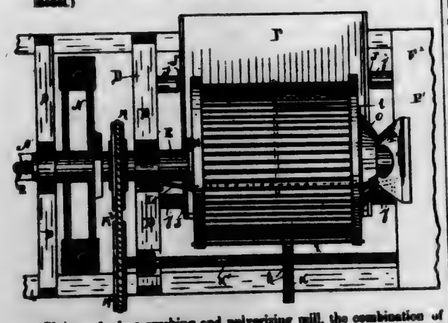


705,869. SUGAR-REFINING APPARATUS. JOSEPH ROSEN-LAUBLES, Paris, France. Filed June 26, 1901. Serial No. 66,977. (No model.)



Claim.—The herein-described sugar-refining apparatus, consisting of a series of successive batteries of melting-pans, coolers and centrifugals so located that the sugar passes from pan to cooler and then to the centrifugal, with means connecting the successive batteries to cause dissolving liquid to travel through the successive batteries from the last toward the first, and to cause the sugar to travel through the same batteries but from the first toward the last, as and for the purpose described.

705,870. CRUSHING AND PULVERIZING MILL. JOHN F. SANDERS, Boise, Idaho. Filed May 10, 1901. Serial No. 59,611. (No model.)



Claim.—1. In a crushing and pulverizing mill, the combination of a rotatable cylinder or drum, longitudinal bars set apart to leave spaces or interstices between them and forming the body of the cylinder or drum, supporting-heads one at each end of the cylinder or drum each head having a circular groove open to its periphery or rim and receiving the end of the bars, a continuous circumferential hoop or band for each head circumscribing the head and the ends of the bars for retaining the bars in place, a rotatable tubular shaft on which the cylinder or drum is mounted, holes or perforations in the shaft within the cylinder or drum, a pipe leading into the shaft for supplying water thereto and discharging the water into the interior of the cylinder or drum through the holes or perforations, an amalgamating-plate located beneath the cylinder or drum, a cam-wheel engaging the end of the amalgamating-plate, a shaft on which the cam-wheel is mounted, and a power connection between the shaft of the cam-wheel and the tubular shaft for revolving the cylinder or drum and reciprocating the amalgamating-plate from a common source of power, substantially as described.

2. In a crushing and pulverizing mill, the combination of a rotatable cylinder or drum, longitudinal bars set apart to leave spaces or interstices between them and forming the body of the cylinder or drum, supporting-heads one at each end of the cylinder or drum receiving and retaining the ends of the bars, a rotatable tubular shaft on which the cylinder or drum is mounted, holes or perforations in the shaft within the cylinder or drum, a water-supply pipe entered into one end of the shaft and discharging water thereinto and escaping the water through the holes or perforations into the interior of the cylinder or drum, openings in one of the heads of the cylinder or drum, a funnel or hopper attached to the head having the openings and revolving therewith and receiving thereinto the ore for depositing the ore within the interior of the cylinder or drum, means for crushing or pulverizing the ore within the cylinder or drum subject to the action of the discharged water from the tubular shaft, an amalgamating-plate located beneath the cylinder or drum and receiving thereon the pulverized material discharged through the spaces or interstices of the cylinder or drum, a cam-wheel engaging the end of the amalgamating-plate, a shaft on which the cam-wheel is mounted and a power connection between the shaft of the cam-wheel and the tubular shaft for revolving the cylinder or drum and reciprocating the amalgamating-plate from a common source of power, substantially as described.

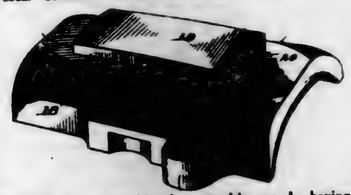
3. In a crushing and pulverizing mill, the combination of a rotatable cylinder or drum, longitudinal bars set apart to leave spaces or interstices between them and forming the body of the cylinder or drum, supporting-heads one at each end of the cylinder or drum receiving and retaining the ends of the bars, a rotatable tubular shaft on which the cylinder or drum is mounted, holes or perforations in the shaft within the cylinder or drum, a water-supply pipe entered into one end of the shaft and discharging water thereinto and escaping the water through the holes or perforations into the interior of the cylinder or drum, openings in one of the heads of the cylinder or drum, a funnel or hopper attached to the head having the openings and revolving therewith and receiving thereinto the ore for depositing the ore within the interior of the cylinder or drum, means for crushing or pulverizing the ore within the cylinder or drum subject to the action of the discharged water from the tubular shaft, an amalgamating-plate located beneath the cylinder or drum and receiving thereon the pulverized material discharged through the spaces or interstices of the cylinder or drum, a rod attached to the bottom of the amalgamating-plate, a resistance-spring operating against the rod, a cam-wheel engaging the end of the amalgamating-plate, a shaft on which the cam-wheel is mounted and a power connection between the shaft of the cam-wheel and the tubular shaft for revolving the cylinder or drum and reciprocating the amalgamating-plate from a common source of power, substantially as described.

4. In a crushing and pulverizing mill, the combination of a rotatable cylinder or drum, longitudinal bars set apart to leave spaces or interstices between them and forming the body of the cylinder or drum, supporting-heads one at each end of the cylinder or drum receiving and retaining the ends of the bars, a rotatable tubular shaft on which the cylinder or drum is mounted, holes or perforations in the shaft within the cylinder or drum, a water-supply pipe entered into one end of the shaft and discharging water thereinto and escaping the water through the holes or perforations into the interior of the cylinder or drum, openings in one of the heads of the cylinder or drum, a funnel or hopper attached to the head having the openings and revolving therewith and receiving thereinto the ore for depositing the ore within the interior of the cylinder or drum, means for crushing or pulverizing the ore within the cylinder or drum subject to the action of the discharged water from the tubular shaft, an amalgamating-plate located beneath the cylinder or drum and receiving thereon the pulverized material discharged through the spaces or interstices of the cylinder or drum, rollers on which the amalgamating-plate is supported one of the rollers located in a higher plane than the other, a cam-wheel engaging the end of the amalgamating-plate, a shaft on which the cam-wheel is mounted and a power connection between the shaft of the cam-wheel and the tubular shaft for revolving the cylinder or drum and reciprocating the amalgamating-plate from a common source of power, substantially as described.

5. In a crushing and pulverizing mill, the combination of a rotatable cylinder or drum, longitudinal bars set apart to leave spaces or interstices between them and forming the body of the cylinder or drum, supporting-heads one at each end of the cylinder or drum receiving and retaining the ends of the bars, a rotatable tubular shaft on which the cylinder or drum is mounted, holes or perforations in the shaft within the cylinder or drum, a water-supply pipe entered into one end of the shaft and discharging water thereinto and escaping the water through the holes or perforations into the interior of the cylinder or drum, openings in one of the heads of the cylinder or drum, a funnel or hopper attached to the head having the openings and revolving therewith and receiving thereinto the ore for depositing the ore within the interior of the cylinder or drum, means for crushing or pulverizing the ore within the cylinder or drum subject to the action of the discharged water from the tubular shaft, an amalgamating-plate located beneath the cylinder or drum and receiving thereon the pulverized material discharged through the spaces or interstices of the cylinder or drum, a cam-wheel engaging the end of the amalgamating-plate, a shaft on which the cam-wheel is mounted and a power connection between the shaft of the cam-wheel and the tubular shaft for revolving the cylinder or drum and reciprocating the amalgamating-plate from a common source of power, substantially as described.

6. In a crushing and pulverizing mill, the combination of a rotatable cylinder or drum, longitudinal bars set apart to leave spaces or interstices between them and forming the body of the cylinder or drum, supporting-heads one at each end of the cylinder or drum receiving and retaining the ends of the bars, a rotatable tubular shaft on which the cylinder or drum is mounted, holes or perforations in the shaft within the cylinder or drum, a water-supply pipe entered into one end of the shaft and discharging water thereinto and escaping the water through the holes or perforations into the interior of the cylinder or drum, openings in one of the heads of the cylinder or drum, a funnel or hopper attached to the head having the openings and revolving therewith and receiving thereinto the ore for depositing the ore within the interior of the cylinder or drum, means for crushing or pulverizing the ore within the cylinder or drum subject to the action of the discharged water from the tubular shaft, an amalgamating-plate located beneath the cylinder or drum and receiving thereon the pulverized material discharged through the spaces or interstices of the cylinder or drum, a cam-wheel engaging the end of the amalgamating-plate, a shaft on which the cam-wheel is mounted and a power connection between the shaft of the cam-wheel and the tubular shaft for revolving the cylinder or drum and reciprocating the amalgamating-plate from a common source of power, and deflecting-plates one on each side of the cylinder or drum at the bottom thereof with their lower ends adjacent to the upper face of the amalgamating-plate for guiding the material discharged from the cylinder or drum onto the amalgamating-plate, substantially as described.

705,871. JOURNAL-BEARING. GEORGE H. SCHEIB, Chicago, Ill., assignor of one-half to George A. Woodman, Chicago, Ill. Filed Mar. 31, 1902. Serial No. 100,778. (No model.)



Claim.—1. A car journal-bearing comprising a wedge having a substantially rectangular recess in its under face, and a brass provided on its top face with a raised crown to work in said recess in the wedge.

2. A car journal-bearing comprising a wedge having a recess in its under face, and a brass provided on its top face with a raised crown to work in the recess in the wedge, said crown being shorter in length than the recess to enable the brass to move endwise relative to the wedge.

3. A car journal-bearing comprising a wedge having a substantially rectangular recess in its under face, and a brass provided on its top face with a raised crown to work in the recess in the wedge, said crown being narrower than the recess to enable the brass to have a slight sidewise and rotary movement relative to the wedge.

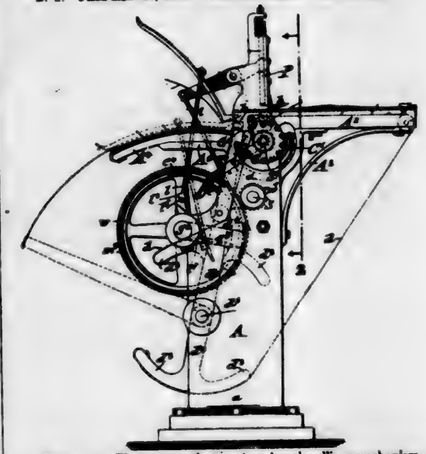
4. A car journal-bearing comprising a wedge having a recess in its under face, and a brass provided on its top face with a raised crown to work in the recess in the wedge, said crown being shorter and narrower than the recess to enable the brass to move endwise and sidewise and rotatably relative to the wedge.

5. A car journal-bearing comprising a wedge having in its under face a substantially rectangular recess with curved end walls, and a brass provided on its top face with a raised crown to work in the recess in the wedge and having curved ends.

6. A car journal-bearing comprising a wedge having a substantially rectangular recess in its under face and depending sides provided with inclined inner faces, and a brass provided with inclined sides and having a raised crown to work in the recess in the wedge.

7. A car journal-bearing comprising a brass having a raised crown on its top face, and a wedge provided on its under face with a substantially rectangular recess of less depth than the height of the crown to receive the crown on the brass and having side and end walls to confine the brass but permitting a limited movement thereof.

705,872. CIGAR-MACHINE. HANS A. SCHERMERHORN, New York, N. Y. Filed Mar. 27, 1901. Serial No. 53,073. (No model.)



Claim.—1. The combination, with a bunch-rolling mechanism, of an intermittently-rotating mold-cylinder, an endless mold-carrying apron working in conjunction with the mold-cylinder, a delivery mechanism for transferring the bunches from the pockets of the mold-cylinder, an oscillating shelf for receiving said bunches, and a cigar-rolling mechanism to which the bunches are delivered from the shelf, substantially as set forth.

2. In a cigar-machine, the combination of a bunch-rolling mechanism, consisting of a stationary table having guideways, a pivoted and spring-cushioned bunch-rolling table, a reciprocating slide-plate, oscillating disks, an apron attached at its rear end to the front end of said slide-plate and at its opposite end to said oscillating disks, said slide-plate being provided with an opening, corresponding to the shape of the cigar, near its rear end, a vertically-reciprocating plunger passing through said opening, and an intermittently-rotating mold-cylinder having pockets that are placed vertically in line with said opening and plunger for receiving the bunch delivered by the bunch-rolling mechanism, substantially as set forth.

3. In a cigar-machine, a bunch-rolling mechanism consisting of a stationary table having guideways, a pivoted and spring-cushioned bunch-rolling table, a slide-plate guided in said ways, oscillating disks, an apron attached at its rear end to the slide-plate and at its front end to said oscillating disks, and mechanism for imparting reciprocating motion to said slide-plate for rolling the bunch and delivering the same at the end of the forward motion of the slide-plate, substantially as set forth.

4. In a cigar-machine, the combination, with a horizontal table having guideways, of a pivoted and yielding rolling-table, a reciprocating slide-plate guided in said ways, oscillating disks connected by a transverse bar, a rolling-apron attached at its rear end to the slide-plate and at its front end to said transverse bar carried by the oscillating disks, a vertically-guided stop-block guided in the rear end of the slide-plate and forming with the same an opening corresponding in shape to the bunch, said stop-block being provided with laterally-projecting lugs at its ends, inclined guide-rails on the guideways of the table for raising the stop-block so as to permit its passage over the rolling-table, and mechanism for reciprocating the slide-plate so as to produce the rolling of the bunch, substantially as set forth.

5. In a cigar-machine, the combination, with a horizontal table having guideways, of a pivoted and yielding rolling-table, a reciprocating

slide-plate guided in said ways, oscillating disks connected by a transverse bar, a rolling-apron attached at its rear end to the slide-plate and at its front end to said transverse bar carried by the oscillating disks, a vertically-guided stop-block guided in the rear end of the slide-plate and forming with the same an opening corresponding in shape to the bunch, said stop-block being provided with laterally-projecting lugs at its ends, inclined guide-rails on the guideways of the table for raising the stop-block so as to permit its passage over the rolling-table, mechanism for reciprocating the slide-plate so as to produce the rolling of the bunch, a reciprocating plunger, a mold-cylinder for taking up the bunch on its delivery from the rolling mechanism, and a curved rearwardly-extending heel adapted to engage the lugs of the stop-block and bring the same in proper position relatively to the plunger, substantially as set forth.

6. The combination, with a bunch-rolling mechanism, of a mold-cylinder provided with a number of pockets, a stationary block vertically above the mold-cylinder and provided with an opening for the bunch, a reciprocating plunger adapted to transmit the bunch, when delivered by the bunch-rolling mechanism, into one of the molds of the mold-cylinder, an endless mold-carrying apron moving in contact with the pockets of the mold-cylinder for holding the bunches in position before delivering them to the cigar-rolling mechanism, means mounted outside of and independent of the mold-cylinder for clearing or removing the bunches from the same, and mechanism for imparting intermittent rotary motion to the mold-cylinder and apron, substantially as set forth.

7. In a cigar-machine, the combination of a bunch rolling and delivering mechanism, with an intermittently-rotating mold-cylinder having pockets for receiving the bunches, and an endless mold-carrying apron moving in conjunction with said mold-cylinder, said mold-cylinder being provided with circumferential slits, and oscillating clearing-fingers in said slits for delivering the bunches from the pockets of the mold-cylinder, substantially as set forth.

8. In a cigar-machine, the combination, with a bunch rolling and delivering mechanism, of an intermittently-rotating mold-cylinder, provided with a number of pockets, and a plurality of circumferential slits, an endless mold-carrying apron moving in conjunction with said mold-cylinder, means for guiding said apron so as to hold its mold-sections in contact with the pockets of the mold-cylinder, oscillating clearing-fingers moving in the radial slits of the mold-cylinder, a vertically-reciprocating plunger for transmitting the bunches into the pockets of the cylinder, and means between said plunger and the oscillating fingers for operating the same on the descent of the plunger, so as to deliver the bunches successively from the pockets of the mold-cylinder, substantially as set forth.

9. In a cigar-machine, the combination, with an intermittently-rotating mold-cylinder having pockets for receiving the bunches, and a plurality of circumferential slits, of an endless mold-carrying apron moving in conjunction with said cylinder, means for guiding the same for bringing the molds in contact with the lower part of the mold-cylinder, oscillating clearing-fingers moving in the radial slits of the mold-cylinder for delivering the bunches from the mold-cylinder, and a shelf provided with seats for receiving the bunches, and means for oscillating said shelf for delivering one bunch after the other to the rolling mechanism, substantially as set forth.

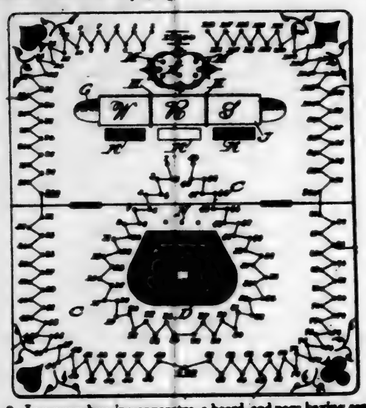
10. In a cigar-machine, a cigar-rolling mechanism consisting of a rolling-table, a rolling-apron extending over the same, the front end of said apron being attached to the outer end of the rolling-table, an oscillating delivery-shelf to which the rear end of the rolling apron is attached, a guard-plate, and means for oscillating said guard-plate so as to place it in position over the rolling-table, substantially as set forth.

11. In a cigar-machine, a cigar-rolling mechanism consisting of a laterally-shiftable rolling-table, a rolling-apron extending over the same, an intermediate carded layer between the table and apron, an oscillating shelf, said rolling-apron being attached at its rear end to the shelf and at its front end to said table, means for oscillating the shelf so as to roll the bunch into the wrapper, and an oscillating guard-plate placed in position over the rolling-table when the rolling motion takes place, substantially as set forth.

12. In a cigar-machine, a cigar-rolling mechanism, consisting of a rolling-table, a rolling-apron extending over the same, an oscillating shelf, said rolling-apron being attached at its front end to the rolling-table and at its rear end to the shelf, means for oscillating said shelf, for rolling the bunch into the wrapper, an oscillating guard-plate adapted to be placed in position over the rolling-table for rolling the bunch into the wrapper, and leaf-springs attached to said guard-plate for holding the wrapper in position while the bunch is delivered into the same, substantially as set forth.

705,873. GAME-BOARD. MAX SCHMIDT, Philadelphia, Pa. Filed Feb. 5, 1902. Serial No. 92,610. (No model.)

Claim.—1. In a score-keeping apparatus of the character stated, a board having a recess and means bridging said recess for retaining strips or tablets for the order of playing.

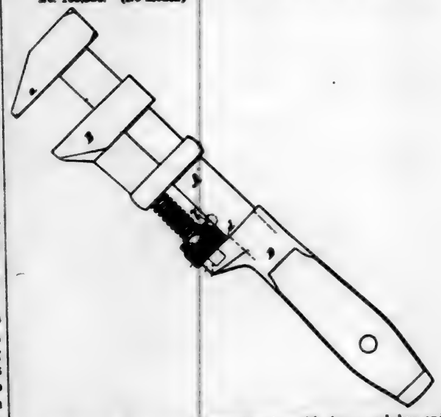


2. In a score-keeping apparatus, a board, and pegs having centrally-disposed recesses and tapered ends whereby said pegs are adapted to be inserted into said board and into each other.

3. In a score-keeping apparatus of the character stated, a board having numbered openings thereon and a recess with bars extending across the same, and tablets removably inserted under said bars and in said recess for the order of playing.

4. In a score-keeping apparatus of the character stated, a board having openings and pegs each provided with an axially-disposed opening, thus adapting said pegs to be inserted into any of the openings of the board and into each other.

705,874. CONSTRUCTION OF WRENCHES. HARRY SEARLE, Worcester, Mass., assignor to Coes Wrench Company, Worcester, Mass., a Corporation of Massachusetts. Filed Apr. 18, 1902. Serial No. 103,566. (No model.)



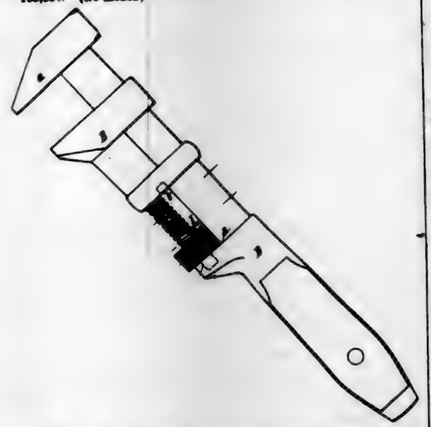
Claim.—1. In a wrench, in combination with the wrench-bar, and jaw-adjusting screw; a protuberant retaining member or keeper supported within a cavity formed in the front face of the wrench-bar, and projecting beyond the plane of the wrench-bar face and over a portion or shoulder of the rosette of the jaw-adjusting screw, for the purpose set forth.

2. In a wrench of the character described, the combination with the wrench-bar, and the jaw-adjusting screw; of a rotatable retaining member or keeper supported in a recess in the face of the wrench-bar, and engaging with an offset groove or bearing-surface upon the rosette or boss of the jaw-adjusting screw and counting therewith to prevent endwise displacement of said screw.

3. In a wrench having a sliding jaw, and a jaw-adjusting screw journaled in the collar projection, with its rosette clear of the front of the bar, the rosette provided with a circumferential groove, offset or bearing-surface, and a rolling retaining ball or member disposed in a cavity formed in the face of the wrench-bar and protruding therefrom and acting against said rosette-surface, substantially as set forth.

4. In a wrench, in combination, for the purposes set forth, a wrench-bar having in its face a socket, recess or cavity with a seating point or elevation on the interior thereof, a rotatable ball loosely supported within said socket by said seating-point and the rim of the cavity, and protuberant from the face of the wrench-bar, the jaw-adjusting screw journaled in the projecting portion of the handle-frame and provided with a rosette or boss having a circumferential bearing groove or surface engaging against said ball, and confining it loosely in connection with its cavity, and said screw in turn thereby confined to its journal-bearing.

705,875. CONSTRUCTION OF WRENCHES. HARRY SEARLE, Worcester, Mass., assignor to Coes Wrench Company, Worcester, Mass., a Corporation of Massachusetts. Filed Apr. 18, 1902. Serial No. 103,567. (No model.)



Claim.—1. In a wrench of the class described, the combination with the wrench-bar, the handle-frame or collar portion carrying the bearing-stop, the slidable jaw, and the jaw-adjusting screw journaled in said stop, and having the rosette thereon standing clear of the front plane of the wrench-bar; of a guard pin or stud inserted and solidly fixed at one end in the metal of the front edge of said wrench-bar, with its projecting outer end in overlying engagement with the rosette, and confining said adjusting-screw against endwise displacement.

2. In a wrench of the character described, in combination with the wrench-bar; the screw-supporting stop and the jaw-adjusting screw, of guard pin or stud inserted in an opening in the front of the wrench-bar above the top edge of the rosette, and solidly incorporated therein by staking in the metal of the bar around the neck of the pin, the head of the pin projecting outward above the rosette, substantially as set forth.

3. In combination, with the wrench-bar, the sliding jaw, the handle-frame and the adjusting-screw having the rosette thereon; a guard-pin fixedly inserted in the front of said wrench-bar, and having the head or projecting portion of greater width than the inserted portion, for the purpose set forth.

4. In a wrench of the character described, in combination, with the wrench-bar, the handle-collar, and jaw-adjusting screw having the rosette thereon; a protuberant pin or retaining member supported in the wrench-bar and projecting over the edge of the rosette for endwise confinement of the screw, and the slidable jaw arranged on said wrench-bar and screw, said jaw being provided with a recess or cavity at its lower end into which said retaining member is received when said jaw is at fully-opened position.

705,876. CONVEYER-BELT. WILLIAM J. SELLENS, Riverside, Conn. Filed May 31, 1902. Serial No. 109,601. (No model.)

Claim.—1. The combination with a conveyer-belt consisting in a plurality of longitudinal sections, of a hinge flexibly uniting said sections composed of parts movably joined together and rigidly secured to the adjoining edges of said sections.

2. The combination with a conveyer-belt composed of a plurality of longitudinal sections, of lacings passing through the adjoining edges of said sections, and means for flexibly uniting said lacings.

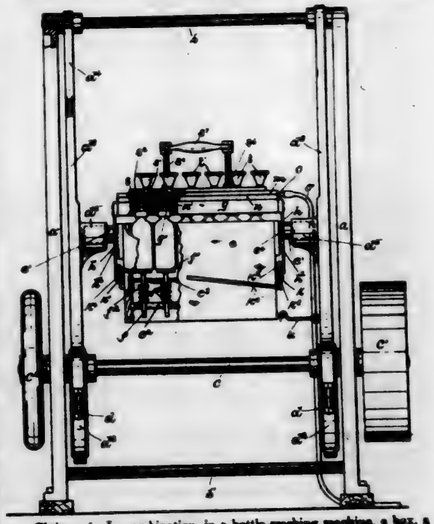
3. The combination with a conveyer-belt composed of a plurality of longitudinal sections, of coil-spring lacings passing through each of the adjoining edges of said sections, and a thong extending through the overlapped convolutions of the lacings.

4. The combination with a conveyer-belt composed of a plurality of longitudinal sections, of coil-spring lacings having elliptical convolutions passing through the adjoining edges of said sections, the projecting portions of said convolutions being overlapped, and a leather thong extending through the registering overlapped convolutions of said lacings.

5. In a conveyer-belt, the combination with central and side sections, of a hinge flexibly uniting said sections composed of parts movably joined together and rigidly secured to the adjoining edges of said sections.

6. In a conveyer-belt, the combination with central and side sections, of lacings passing through the adjoining edges of said sections, and means for flexibly uniting said lacings.

705,877. BOTTLE-WASHING MACHINE. MICHAEL P. SHEA, New London, Conn. Filed Oct. 17, 1901. Serial No. 78,906. (No model.)



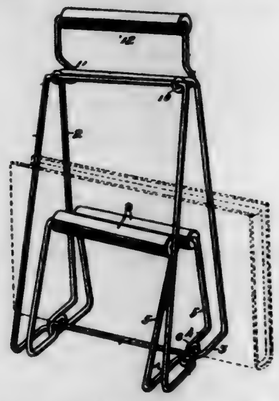
Claim.—1. In combination, in a bottle-washing machine, a box, a cover having depressions g', means for retaining a multiple of bottles in engagement with said depressions, and means for locking the said cover to the box consisting of teeth affixed to the opposite ends of the box, and depending spring-tongues on the cover having teeth to intermesh with the teeth on the box.

2. In combination, in a bottle-washing machine, a box, a cover having depressions g', means for retaining bottles in engagement with said depressions, and means for locking the said cover to the box consisting of teeth affixed to opposite ends of the box, and depending spring-tongues having teeth to engage with the teeth on the box, and means for unlocking the same consisting of levers k^2 k^3 pivotally mounted on the box with their free ends arranged to engage the free ends of said spring-tongues and connecting-rod k^4 joining the levers at the opposite ends of the box as specified.

3. In a bottle-washing machine, in combination, a plate *g* having depressions adapted to receive the necks of a multiple of bottles, means for holding said bottles in close engagement with said plate, means for agitating and for inverting said bottles, openings in said plate *g* coincident with the said depressions, and a plate *s* slidably mounted over the plate *g*; said plate *s* being provided with perforations *s'* extending through it and also with shot-chambers *t* having discharge-openings substantially as specified.

4. In a bottle-washing machine, in combination, a plate *g* having depressions adapted to receive the necks of a multiple of bottles and openings leading outward from said depressions, means for holding the bottles in engagement with said depressions, means as set forth for introducing water into said bottles, and a plate slidably mounted over the plate *g*; said plate *s* being provided with perforations *s'* adapted to register with the said depressions when plate *s* is moved in one direction and also with shot-chambers having outlets adapted to register with said depressions when the plates is moved in the opposite direction.

705,878. BOOK OR PARCEL CARRIER OR HOLDER. THEODOR H. SCHUTTENBERG, Hubbard, Ohio. Filed Jan. 30, 1902. Serial No. 91,913. (No model.)



Claim.—1. A device of the class described comprising two sides hinged together at the bottom and adapted to clamp a parcel, and the clamping-jaws arranged at the lower portion of the device and connected with the sides and adapted to engage books or parcels, substantially as and for the purpose described.

2. A device of the class described comprising two sides hinged together at the bottom and spaced apart between their ends when the device is closed, means for holding the sides in their closed position, and the clamping-jaws connected with the sides and operating in the space between the same, whereby the device is adapted to hold and positively engage parcels or packages of different sizes, substantially as described.

3. A device of the class described comprising two sides provided at the bottom with arms hinged together and spacing the sides apart, and clamping-jaws connected with the said arms and operating in the spaces between the sides, substantially as described.

4. A device of the class described comprising sides hinged at the bottom and provided with clamping-jaws operating independently of the sides in clamping packages or books, and a frame hinged at one side to the top thereof and provided with a loop or bend receiving the other side of the device, said hinged frame being also provided with a grip or handle, substantially as described.

5. A device of the class described comprising hinged sides provided with lower clamping-jaws, and the approximately U-shaped frame hinged to one of the sides and provided at opposite sides with approximately U-shaped loops or bends to receive the other side of the device, said hinged frame being also provided with a grip or handle, substantially as described.

6. A device of the class described comprising hinged sides provided at the bottom with inwardly-extending loops, means for hinging the loops together, and clamping-jaws connected with the inner sides of the loops, substantially as described.

7. A device of the class described comprising hinged sides having inwardly-extending loops at their bottom and provided with clamping-jaws, and a rod provided at its end with eyes linked into the said loops and hinging the sides, substantially as described.

8. A device of the class described comprising upwardly-converging sides provided at the bottom with inwardly-extending arms, the upwardly-converging clamping-jaws terminating between the top and bottom of the device and provided with arms connected with the said arms and forming loops, and means for connecting the loops, whereby the sides are hinged together, substantially as described.

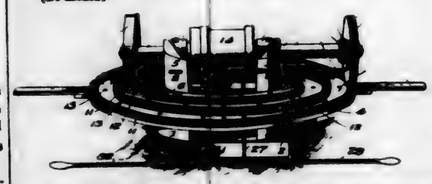
9. A device of the class described comprising sides constructed of a single piece of resilient material and provided at the bottom with inwardly-extending arms, the clamping-jaws provided with cross-pieces and having sides formed integral with the sides of the device and provided with arms connected with the said arms and forming loops, and means for hinging the loops together, substantially as described.

10. A device of the class described comprising sides provided at the bottom with inwardly-extending loops, clamping-jaws consisting of side portions formed integral with the said loops, and the connecting-bars having the upper terminals of the side portions embedded in them, and means for hinging the loops, substantially as described.

705,879. DRAWER-SUPPORTER. HARMON C. SMITH, Ithaca, N. Y. Filed Apr. 16, 1901. Serial No. 56,123. (No model.)

Claim.—A garment-supporter consisting of a plate adapted for attachment to a garment, and a hook comprising parallel shank members rigidly attached at one end to the plate and having their terminals bent and entered therein, diverged side bars and loops at the sides of the shank and between it and the side bars, the terminal of the hook being bent outward away from the plane of the hook, and the shank and the body of the hook being oppositely deflected, substantially as specified.

705,880. SWEEP-OPERATED HOISTING-WINDLASS. BYRON B. BYRNES, Crippleereek, Colo. Filed Sept. 4, 1901. Serial No. 74,269. (No model.)



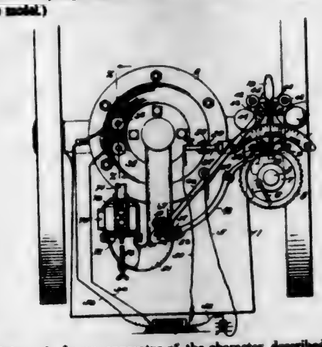
Claim.—1. In a machine of the class described, the combination with a rotary power-table having a plurality of concentric gear-tracks, of a rotary shaft extending transversely of the table, a guide-wheel journaled on the shaft at one side of the center of the table and bearing against the latter in the space between the gear-tracks, and a pinion slidably mounted on the shaft on the opposite side of the center of the table and adapted to engage with either of the gear-tracks so as to turn with the table and the shaft being adapted to turn with the pinion.

2. In a machine of the class described, the combination with a rotary power-table having concentric gear-tracks, of separated bearings located on opposite sides of the center of rotation of said power-table, a shaft journaled in said bearings, a winding-drum secured on the shaft intermediate the bearings, a guide-wheel loosely journaled on one end of the shaft and adapted to bear against the table between the gear-tracks, and a pinion slidable longitudinally on the shaft and adapted to turn therewith, which is arranged to mesh with any of the gear-tracks.

3. In a machine of the class described, the combination with a frame, of a table adapted to turn thereon, a shaft journaled to turn in the frame, a wheel on the shaft adapted to engage the table and slidable longitudinally on the shaft, a rod slidably mounted in the frame and connected to the wheel, said rod having an open arm, a pivoted member having a projection movable in the opening in the arm and a lever for operating said pivoted member, whereby the wheel may shift on the shaft.

4. In a machine of the class described, the combination with a frame having an upright portion and provided with antifriction-rollers, of a table having concentric gear-tracks and provided with an open central portion turning on the upright portion of the frame and being supported by the antifriction-rollers, a shaft journaled in the upright portion of the frame, a winding-drum on said shaft between the portions of the upright part of the frame, a friction-brake having one end secured to the frame and its remaining portion adapted to act on the drum, lever mechanism for operating said friction-brake, a guide-wheel journaled on the shaft and adapted to bear against the table, a pinion slidable longitudinally of the shaft at the opposite end from the guide-wheel and adapted to turn with the shaft, a rod slidably mounted on the frame and connected to the pinion, said pinion being adapted to engage the tracks, said rod having a member provided with an elongated slot, a member pivoted to the frame and provided with a projection received in the slot, and lever mechanism for operating said member, whereby the shifting of the pinion is accomplished.

705,881. GAS-ENGINE IGNITION-REGULATOR. MICHAEL J. SULLIVAN, Springfield, Ohio. Filed Jan. 13, 1902. Serial No. 89,410. (No model.)



Claim.—1. In an apparatus of the character described, a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, a segment-bar lying in the plane of rotation of said arm, its center of curvature being the center of rotation of said arm, and a head provided with a contact-block and adjustable longitudinally on said bar, substantially as described.

2. In a sparking electric ignition device for gas-engines, the combination, with suitable electrodes, of a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, a segment-bar lying in the plane of rotation of said arm, its center of curvature being the center of rotation of said arm, and a head provided with a contact-block and adjustable longitudinally on said bar, and a governor driven by the engine and operatively connected with said block to shift the same, substantially as described.

3. In a sparking electric ignition device for gas-engines, the combination, with suitable electrodes, of a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, a segment-bar lying in the plane of rotation of said arm, its center of curvature being the center of rotation of said arm, and a head provided with a contact-block and adjustable longitudinally on said bar, a governor also driven by the engine and operatively connected with said block to shift the same, and a valve controlling the charge-inlet and operatively connected with the governor to work in unison with the shifting contact-block, substantially as described.

4. In an apparatus of the character described, a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, a segment-bar lying in the plane of rotation of said arm, its center of curvature being the center of rotation of said arm, and a head provided with a yielding contact-block and adjustable longitudinally on said bar, substantially as described.

5. In an apparatus of the character described, a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, a segment-bar lying in the plane of rotation of said arm, its center of curvature being the center of rotation thereof, said bar being longitudinally slotted, a head grooved to fit and slide in said slotted bar and provided with a contact-block and a clamping-block, and a handle threaded into said head and operating the clamping-block, substantially as described.

6. In an apparatus of the character described, a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, a segment-bar lying in the plane of rotation of said arm, its center of curvature being the center of motion thereof, a head adapted to slide longitudinally on said bar and provided with clamping means, lugs depending from said head and connected by a transverse pin, a contact-block fitting between said lugs and vertically slotted to receive the pin, and springs interposed between said block and head on each side of the pin, substantially as described.

7. In an apparatus of the character described, the combination, with a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, and a contact-block adjustable in the plane of rotation of said arm and in an arc whose center is the center of motion thereof, of a governor driven by the engine, and connecting mechanism between said governor and contact-block for shifting said block, said mechanism comprising means for regulating the portion of the arc of movement of said block over which the governor shifts the same, substantially as described.

8. In an apparatus of the character described, the combination, with a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, and a contact-block adjustable in the plane of rotation of said arm and in an arc whose center is the center of motion of said arm, of a governor driven by the engine, and connecting mechanism between said governor and contact-block for shifting the block, said connecting mechanism comprising means for regulating the extent of the motion imparted to the block by the governor, substantially as described.

9. In an apparatus of the character described, the combination, with a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, and a contact-block adjustable in the plane of rotation of said arm and in an arc whose center is the center of motion of said arm, of a governor driven by the engine, and connecting mechanism between the governor and contact-block to shift the latter, said connecting mechanism comprising means for regulating the portion of the arc of movement of the block over which the governor shifts said block, and also means for regulating the extent of motion within that portion of the arc imparted to the block by the governor, substantially as described.

10. In an apparatus of the character described, the combination, with a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, and a contact-block adjustable in the plane of rotation of said arm and in an arc whose center is the center of motion of said arm, of a governor driven by the engine, connecting mechanism between said governor and contact-block to shift the latter, and means for rendering said connecting mechanism inoperative at will, substantially as described.

11. In an apparatus of the character described, the combination, with a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, and a contact-block adjustable in the plane of rotation of said arm and in an arc whose center is the center of motion of said arm, of a governor driven by the engine, a rock-shaft operated by said governor and provided with a crank-arm, a crank-pin adjustable on said crank-arm, and a link operatively connected with the contact-block and adjustably connected with the crank-pin, substantially as described.

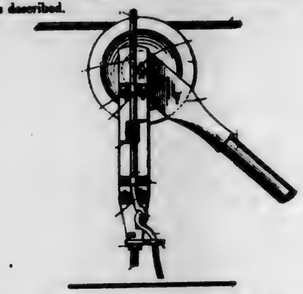
12. In an apparatus of the character described, the combination, with a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, and a contact-block adjustable in the plane of rotation of said arm and in an arc whose center is the center of motion of said arm, of a governor driven by the engine, a charge-inlet pipe having a rock-shaft connected with the governor and provided with a controlling-valve located within said pipe, said rock-shaft being provided with a crank-arm, and a link connecting said crank-arm and the contact-block, substantially as described.

13. In an apparatus of the character described, the combination, with a circuit-making device comprising a rotating part driven by the engine and provided with a contact-arm, a segment-bar located in the plane of rotation of said arm, its center of curvature being the center of motion thereof, and a head provided with a contact-block, said head being movable longitudinally on said arm and having clamping devices to engage the bar, of a governor, connecting mechanism between said governor and the head, a handle threaded into the head and controlling the clamping devices, and a spring interposed between the head and handle to prevent accidental clamping action by the handle, substantially as described.

705,882. TROLLEY. THOMAS W. BUTTON, Pittsburg, Pa. Filed May 7, 1902. Serial No. 106,267. (No model.)

Claim.—1. In a trolley, the combination with a harp, an axle mounted in said harp and extended beyond the sides of the latter, a pin passing through the ends of the harp and through said axle and a trolley-wheel mounted on the axle within the harp, of a yoke comprising a pair of cheek-plates mounted at their upper ends on the extended ends of the axle and secured together at their lower ends, retaining-rods journaled in keepers secured to said plates and rotatable in said keepers, the upper ends of said arms being extended inwardly, a keeper carried at the lower end of the yoke, means connected to the lower ends of the rods or arms and passing through said keeper for rotating the rods, said springs arranged on said rods for normally holding the same in the retaining position, substantially as described.

2. In a trolley, the combination with a trolley-harp, an axle mounted therein and extended beyond the sides of the harp and a trolley-wheel mounted on said axle, a pin passing through said harp and said axle, of a yoke embodying a pair of check-plates connected to a spacer-block at their lower ends, retaining-rods journaled in keepers on the outer face of said plates and rotatable in said keepers, springs arranged on said rods and bearing against the check-plates for normally holding the rods in a retaining position, a keeper carried by the spacer-block, an operating-cord extending through said keeper and connected to each of the retaining-rods, and means carried by the spacer-block for securing a weight thereto, substantially as described.



705,888. ICE-CAN. FLETCHER D. SWAREY, Kansas City, Kans., assignor of one-half to Herbert Galer, Kansas City, Kans. Filed June 13, 1901. Serial No. 64,462. (No model.)

Claim.—1. An ice-can, comprising a body portion, constructed of two similar sections formed at their outer sides with hooks 5, terminating short of the upper ends of the sections; plates 6, provided with hooks 7, interlocked with hooks 5, said plates terminating at their upper ends coincidently with said hooks 5; a bottom; a reinforced band, encircling the body portion above said hooks 5 and plates 6; and a second band, the same being provided with a hook above hooks 5 and plates 6, and underlying the reinforce-band, and interlocked with the upper end of the body portion, substantially as described.

2. An ice-can, comprising a body portion constructed of two similar sections formed at their outer sides with hooks 5 and at their lower ends with external upwardly-disposed hooks 10, the outer portions of said hooks lapping the lower ends of said sections and their hooks 5; plates 6, provided with hooks 7 interlocked with hooks 5, said plates terminating at their lower ends flush with said hooks 5, as to be also lapped by said hooks 10; and a bottom, fitting in the body portion and provided with upwardly-disposed hooks 9, externally embracing hooks 10, and downwardly-disposed hooks 9', interlocked with hooks 9, substantially as described.

3. An ice-can provided with upwardly-disposed hooks at its upper end, a reinforce-band encircling the upper end of the can, and a band embracing and interlocked with the reinforce-band to prevent it moving downwardly, and provided at its upper margin and outer side with a downwardly-disposed hook engaging the upwardly-disposed hooks of the can, substantially as described.

705,884. INLET FOR PNEUMATIC-DESPATCH TUBES. FRED R. TAMEY, Indianapolis, Ind., assignor to the Tamey Pneumatic Service Company, Indianapolis, Ind., a Corporation of Indiana. Filed Oct. 14, 1901. Serial No. 78,556. (No model.)

Claim.—1. An inlet for a pneumatic-despatch tube consisting of an inlet-chamber, a spring-closed lid or valve at the outer end thereof, a spring-closed valve for closing the outlet from said chamber, and means for moving said last-named valve laterally out of a closing position.

2. An inlet for a pneumatic-despatch tube consisting of an inlet-tube adapted to serve as a guide for a carrier, a valve-chamber secured to the inner end of said tube which is extended at a right angle from said tube, a valve for closing the outlet from said valve-chamber that is pivotally mounted, and means outside the valve-chamber for oscillating said valve.

3. An inlet for a pneumatic-despatch tube consisting of an inlet-tube, a valve-chamber secured to the inner end of said tube which is extended at a right angle from said tube, a valve for closing the outlet from said valve-chamber that is pivotally mounted, means outside the valve-chamber for oscillating the valve therein, and a rib or track in said casing upon which said valve moves in its oscillation.

4. An inlet for a pneumatic-despatch tube consisting of an inlet-chamber, a valve for closing the outer end thereof, a valve for closing the inner or outlet end thereof, means on the latter valve adapted to support the carrier out of contact with the valve after the carrier has been inserted into said chamber, and external means for moving said valve out of the path of the carrier.

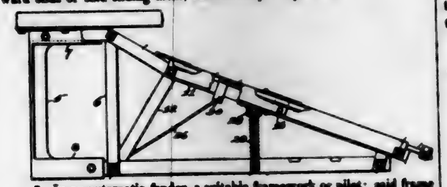
5. An inlet for a pneumatic-despatch tube including an inlet-chamber with an outlet therefrom to the despatch-tube, a valve for closing said outlet, means for moving said valve laterally to open said outlet, and a collar on said valve to support a carrier before the valve is actuated, said collar being slotted on one side substantially as shown.

705,885. RAIL-JOINT. VICTOR L. TRUXALL, Latrobe, Pa. Filed Feb. 18, 1902. Serial No. 94,614. (No model.)

Claim.—A rail-joint comprising abutting rail-sections each having the ends of their web portions enlarged, a centrally-arranged hook formed integral with one end of one of the rails, said hook having a horizontally-disposed body portion formed integral with the web and being of the same thickness thereof, said body portion of the hook being located considerably below the head of the rail, carrying at its outer end a downwardly-curved extension having one of its edges beveled, the other of said sections formed in its abutting edge with a centrally-arranged horizontally-disposed enlarged recess adapted to normally receive the body portion of the said hook, said recess communicating at its rear end with a vertically-disposed contracted opening extending through the rail-base and adapted to receive the said downwardly-curved extension, substantially as described.

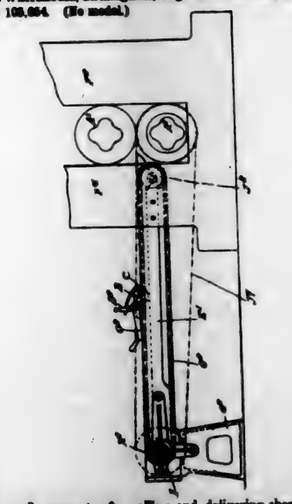
705,886. CAR-FENDER. JOHN W. WEBSTER, St. Louis, Mo. Filed Feb. 24, 1902. Serial No. 95,233. (No model.)

Claim.—1. In an automatic fender, a suitable framework or pilot having bifurcated inclined arms extending backwardly and upwardly from its forward end; bars mounted in the spaces in said bifurcated arms; pivots inserted through said arms and through said bars near their rear ends; a rod connecting the forward ends of said pivoted bars; an apron attached to said rod and extending backwardly and attached to the frame; springs attached to the rear ends of said pivoted bars and to the frame; the tension of said springs being exerted to throw the ends of the pivoted bars upwardly; loops slidingly controlling the bifurcated arms and removably engaging the rear ends of the pivoted bars as required to latch the scoop down in its normal position; arms slidingly mounted on top of the pivoted bars in position to engage said loops and extending forwardly beyond the ends of the pivoted bars; and a feeler-bar connecting the forward ends of said sliding arms, substantially as specified.



2. In an automatic fender, a suitable framework or pilot; said frame or pilot comprising vertical posts, horizontal arms extending forwardly from the lower ends of said vertical posts in a horizontal position, bifurcated inclined arms extending backwardly and upwardly from the forward ends of said horizontal arms, braces connecting the rear ends of said horizontal arms to the rear ends of said bifurcated inclined arms, second bifurcated inclined arms connecting the upper ends of said posts to the upper ends of said braces, and to the rear ends of said first-mentioned bifurcated inclined arms, and a rod connecting the upper ends of said posts; a scoop pivotally mounted on said pilot; said scoop consisting of bars mounted in the spaces in said bifurcated arms, pivots inserted through said arms and through said bars near their rear ends, a rod connecting the forward ends of said pivoted bars, straps connected to said rod and extending backwardly, arms-pieces connecting said straps together, a rod connecting the rear ends of said straps, springs extending backwardly from said rod, a second rod connecting the rear ends of said springs, straps connecting said second rod with the rod connecting the upper ends of said posts, and arms-pieces connecting the last-mentioned straps; springs attached to the rear ends of said pivoted bars and to the frame, the tension of said springs being exerted to throw the forward ends of the pivoted bars upwardly; loops slidingly controlling the bifurcated arms and removably engaging the rear ends of the pivoted bars as required to latch the scoop down in its normal position; arms slidingly mounted on top of the pivoted bars in position to engage said loops said arms extending forwardly beyond the ends of the pivoted bars; and a feeler-bar connecting the forward ends of said sliding arms; so that when the feeler-bar strikes an obstruction the loops are pushed backwardly to release the rear ends of the pivoted bars and allow the forward end of the scoop to swing upwardly, substantially as specified.

705,887. APPARATUS FOR ROLLING FLAT SHEET METAL. THOMAS WHITEHOUSE, Birmingham, England. Filed May 2, 1902. Serial No. 105,984. (No model.)



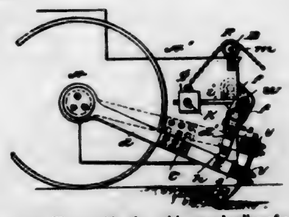
Claim.—In apparatus for rolling and delivering sheet metals in a perfectly flat state from the rolls, the combination with the sheet-finishing rolls, of a draw-bench provided with two endless chains G, G', sprocket-wheels mounted in bearings near the rolls over which said chains pass, a driving-shaft I at the opposite end of the bench, sprocket-wheels thereon over which said chains also pass, a carriage B moving on the draw-bench and having gripping-jaws C D adapted to grip the end of the sheet immediately it has passed through the rolls, dogs carried by the carriage adapted to engage and be disengaged from the chains, and means whereby the depression of the dogs causes the jaws to grip the sheet and the dogs to engage the chains, substantially as described.

705,888. CAR-ROOF. ALVA W. WILOX, Howard, Ohio. Filed Apr. 7, 1902. Serial No. 101,734. (No model.)

Claim.—1. A roof comprising planks each having its upper and lower portions projecting laterally in opposite directions each beyond the other and lying with the projecting upper portion of one upon the projecting lower portion of the other, the projecting lower portion of each plank having a longitudinally-extending channel formed in its upper face, and having an upwardly-extending bead at the outer edge of the channel, and the laterally-extending upper portion of each plank having a groove in its under face in which the bead is fitted to hold the planks against lateral movement with respect to each other, the free end of the laterally-extending upper portion of each plank and the corresponding face of the next plank having one a projection and the other a recess to receive the projection to prevent vertical movement of each plank with respect to the next.

2. A roof comprising planks each having its upper and lower portions projecting laterally in opposite directions each beyond the other, the outer end of the laterally-projecting upper portion of each plank being beveled at an obtuse angle to the upper face of the plank and the opposite side face of the upper portion of each plank being beveled at a complementary angle to the upper face of the plank, and lying with the projecting upper portion of one upon the projecting lower portion of the other, and with the corresponding beveled faces in close contact, the projecting lower portion of each plank having a longitudinally-extending channel formed in its upper face, and having an upwardly-extending bead at the outer edge of the channel, and the laterally-extending upper portion of each plank having a groove in its under face in which the bead is fitted to hold the planks against lateral movement with respect to each other.

705,889. ROAD-BREAKING MACHINE. ISMAEL WRESKI, Gross Dingen, Germany. Filed Nov. 18, 1901. Serial No. 82,786. (No model.)

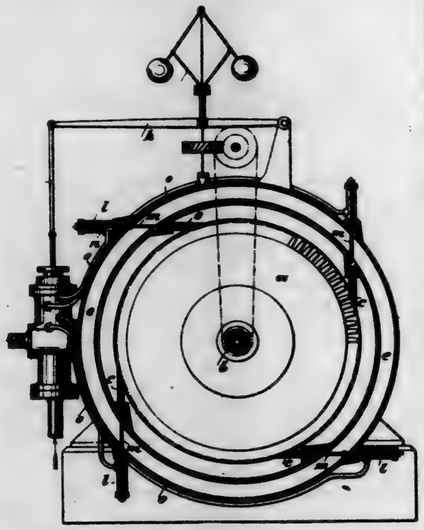


Claim.—1. The combination with a road-roller of a pair of adjustable frames, provided with toothed bars a transverse shaft pivoted to the rear of the road-roller, crank-arms secured to the ends of the shaft and the links connecting the cranks to the frames, a counter adjustable weight secured to the shaft and chains connected to the weights and passing over pulleys mounted on the shaft B, arranged in the brackets secured to the rear of the roller, all substantially as described.

2. In a device of the character described, the combination with the roller, of twin frames pivoted at their forward ends directly to the axle of said roller and arranged on each side thereof, the toothed bars interposed between said frame and the clamping-plate *v* and held in place by the bolts, the cranks secured to the shaft *w* and the links, the lower end thereof pivoted to the frame and the upper end pivoted to said crank, the weights *g* arm *i* and chains K, passing over the pulleys, all substantially as described.

3. The herein-described device for breaking up roads, comprising triangular frames, the forward-extended portions being pivoted to the axle of a road-roller said frames provided with the toothed bars, clamping-plates bolted to the frames between which and the plates said toothed bars are interposed, the crank-shaft journaled to the rear of the roller and having the arms *i i* and weights *g g*; the links *d' d'* interposed between the frames and cranks, and pivoted as described the chains, pulleys and shaft therefor, the latter mounted in brackets secured to the roller, the whole adapted to operate substantially as set forth.

705,890. **STEAM OR GAS TURBINE.** HEINRICH ZOELLY, Zurich, Switzerland. Filed Mar. 31, 1902. Serial No. 100,733. (No model.)



Claim.—1. In a steam or gas turbine, a plurality of inlet-nozzles, an independent valve controlling each nozzle and a piston-valve controlled by the speed of the turbine to separately actuate said valves, substantially as described.

2. In a steam or gas turbine, a plurality of inlet-nozzles, an independent valve controlling each nozzle normally closed and actuated by motive fluid, and a piston-valve controlled by the speed of the turbine to admit and cut off motive fluid to and from said valves in succession, substantially as described.

3. In a steam or gas turbine, the combination with the turbine wheel, of an annular motive-fluid passage surrounding the wheel, a plurality of nozzles leading from the passage, a motive-fluid-actuated valve to control each nozzle and governor-actuated means to control motive fluid to said valves, substantially as described.

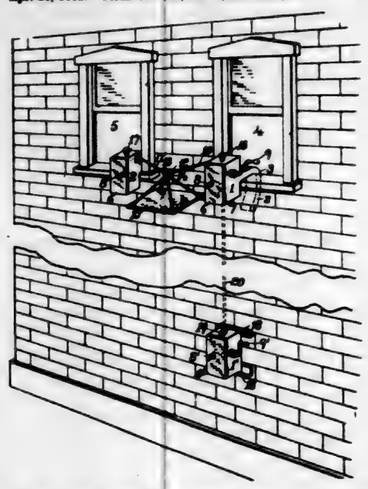
4. In a steam or gas turbine, the combination with the turbine wheel, of an annular motive-fluid passage concentric with the wheel, a plurality of nozzles leading from the passage, a cylinder, a loaded piston and a valve connected to the piston for each nozzle, and a governor-controlled piston-valve to admit and cut off motive fluid to and from said valves successively, substantially as described.

5. In a steam or gas turbine, the combination with the turbine wheel, of a plurality of inlet-nozzles, a regulating-pin for each nozzle to control motive fluid therein, cylinders, a piston in each, and springs to load the pistons, each pin connected to a piston, a separate pipe connection to each cylinder, a controlling-cylinder to which each pipe is connected and a piston-valve, controlled by the speed of the turbine, in said controlling-cylinder to admit motive fluid to and cut it off from the first-mentioned cylinder in succession, substantially as described.

6. In a steam or gas turbine, a plurality of inlet-nozzles, an independent valve controlling each nozzle and actuated by motive fluid, and means controlled by the speed of the turbine to separately control the supply of motive fluid to said valves, substantially as described.

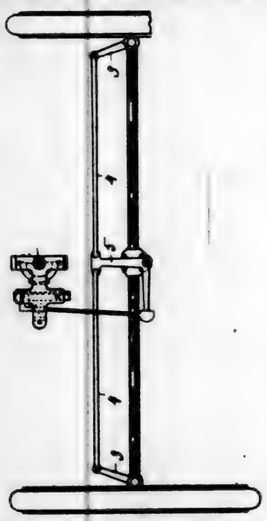
7. In a steam or gas turbine, a plurality of inlet-nozzles, an independent valve controlling each nozzle actuated by motive fluid, and a valve controlled by the speed of the turbine to admit motive fluid to and cut it off from said turbines, substantially as described.

705,891. **FIRE-ESCAPE.** MARIE ABRAHS, New York, N. Y. Filed Apr. 30, 1902. Serial No. 105,947. (No model.)



Claim.—In a portable fire-escape, the combination of the box 1 containing winding mechanism, the box 2, containing winding mechanism, each of said boxes 1 and 2 having sill-hooks 3, the cable 10, the cable 11, and the platform 15, substantially as described.

705,892. **STEERING MECHANISM.** FREDERICK R. ALLEN, Boston, and RAYMOND H. DAFFORTH, Salem, Mass., assignors to the Improvements Manufacturing Company, Boston, Mass., a Corporation of Maine. Filed Dec. 17, 1900. Serial No. 40,088. (No model.)



Claim.—1. In a steering mechanism, the combination of a guiding or steering member, a rotary cam having one or more complete turns or convolutions of a coiled or non-returning groove of uniform width, a movable cam-engaging member connected with said guiding member and having a single circular stud closely fitting said groove at all points in the operating length thereof and movable in a path which remains substantially normal to the groove through one or more complete rotations of the cam whereby the cam-engaging member is locked against movement when the cam is stationary, and means to rotate the cam and thereby impart a steering movement to the cam-engaging member.

2. In a steering mechanism, the combination of a vehicle-body, an underframe movable vertically with respect thereto, a steering wheel or wheels swiveled on said underframe, steering connections mounted on said frame, and a controlling and locking mechanism mounted on the body and including a rotary cam-like locking member, a downwardly-projecting arm connected with said member and movable by its rotation, and a substantially horizontal link connecting the lower end of said arm with the said steering connections.

705,893. **FOLDABLE STOOL.** PAUL B. ANTES, Topeka, Kans., assignor to Topeka Tent and Awning Company, a firm consisting of William Schlick, Frederick A. Antes, and Benjamin W. Carter, Topeka, Kans. Filed Dec. 16, 1901. Serial No. 86,092. (No model.)

Claim.—1. In a foldable stool, the combination, with four legs having parallel sides, and a rectangular spacing-block engaged with the legs between their ends, of a rectangular keeper-band embracing the legs, and pivots passing through perforations in the band and legs and affixed in the spacing-block.

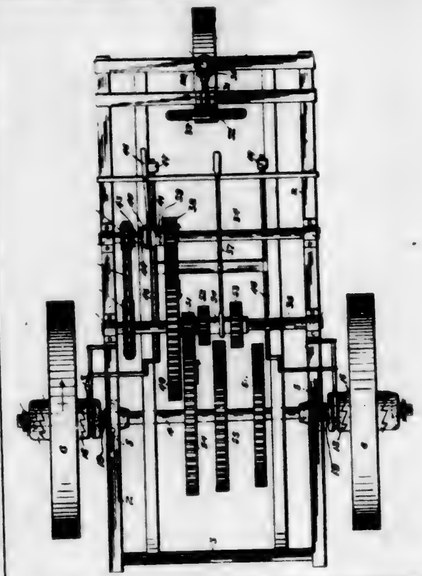
2. In a foldable stool, the combination, with four legs each comprising a straight rectangular strip of wood, and a rectangular spacing-block engaged by a respective side of each leg, of a square keeper-band mounted on the assembled legs, and a pivot for each leg, passing loosely through the band and leg and affixed in the block, each leg having a clearance-notch in a suitable corner to permit the free, full opening of said legs, which is defined by their contact upon the upper and lower edges of the band.

705,894. **DRIVE-GEAR FOR TRACTION-ENGINES.** DAVID R. ARNOLD, Terre Haute, Ind. Filed Oct. 24, 1901. Serial No. 79,231. (No model.)

Claim.—1. The combination with the supporting-frame; of a steering-wheel located at one end thereof, traction-wheels loosely journaled upon the axles of the supporting-frame and provided with clutch members at the opposite ends of their hubs, clutch members located at each end of the axle and locked to rotate therewith and slide longitudinally thereon, springs for holding said clutch members into engagement with the clutches on the outer ends of the hubs, clutch members located upon the axles adjacent to the inner ends of the hubs and locked to rotate therewith and slide thereon and adapted to engage the clutch members at the inner ends of the hubs, and means for shifting the last-named sliding clutch members, substantially as described.

2. The combination with the supporting-frame; of an axle journaled in said supporting-frame and provided at each end with two clutch members keyed to rotate with the axle and slide thereon, traction-wheels loosely journaled upon said axle and each provided with a clutch member at each end of its hub, springs for holding the sliding clutch members into locked engagement with the outer clutch members of the hubs, a second set of clutch members keyed to rotate with and slide upon the axle and located to engage the clutch members on the inner ends of the axles, the teeth of the inner set of sliding clutch members being pitched in one direction and the teeth of the outer set being pitched in an opposite direction, and means for shifting the inner set of clutch members, substantially as specified.

3. The combination with the supporting-frame of a traction-engine; of an axle having a groove at its end, a two-part spline or feather fitted in said groove and provided with legs, a clutch member having a groove to engage one of said legs to cause the clutch member to turn with the spline or feather in the rotation of the axle, a traction-wheel located between two of the legs of the spline or feather and free to rotate therebetween but prevented from having endwise movement on the axle, a second clutch member mounted on the axle and having a groove engaging the outermost leg to lock said clutch member to rotate with said axle but to permit it to have a sliding movement thereon, the hub of said wheel being provided with clutch members to be engaged by the aforesaid clutch members, substantially as set forth.



4. The combination with the supporting-frame of a traction-engine; of a steering-wheel and traction-wheels, clutch devices for locking the traction-wheels to said axle to turn in either direction of movement of said axle, differential gear-wheels fixed to said axle, a drive-shaft, a sprocket-wheel and a gear-wheel loosely mounted upon said drive-shaft, clutch members splined upon said drive-shaft to lock either the gear-wheel or the sprocket-wheel to rotate the said drive-shaft, a counter-shaft suitably mounted in the main frame and provided with differential gear-wheels to engage the differential gear-wheels aforesaid, a gear-wheel fixed to said counter-shaft and adapted to mesh with the gear-wheel on the drive-shaft, a sprocket-wheel fixed to the counter-shaft and connected to the sprocket-wheel of the drive-shaft by a chain and adapted to rotate the counter-shaft in a direction reverse to that when the gear-wheel is in mesh with the fixed gear-wheel on the counter-shaft, and means for shifting the several clutch members, substantially in the manner described.

705,895. **COVERING FOR DEMIJOHNS.** JACOB G. BAER, Brooklyn, N. Y. Filed Jan. 9, 1902. Serial No. 88,967. (No model.)

Claim.—1. A covering for demijohns, comprising a shell made of a woven fabric material, and a lining for the shell made of soft material such as paper, the lining at the spherical body portion of the vessel being formed of rings to conform to the curvature of the said spherical portion, as set forth.

2. A covering for demijohns, comprising a shell made of a woven fabric material made in sections, of which one is the body-section and the other the neck-section, the body-section extending onto the neck portion of the vessel to be overlapped by the lower end of the neck-section, and a lining for the said shell made of a soft material such as paper, the lining consisting of a body-section, rings and a neck-section, as set forth.

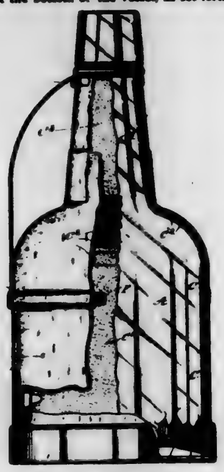
3. A covering for demijohns, comprising a shell, a lining for the same, an annular flange at the lower end of the shell, a metallic ring on the said flange, and prongs carried by the said metallic ring and extending inwardly from the ring to engage the shell at the bottom of the vessel, as set forth.

4. A covering for demijohns, comprising a shell, a lining for the same, a ring interposed between the lining and shell, a neck-band on the vessel, and a handle engaging the neck-band and the said ring, as set forth.

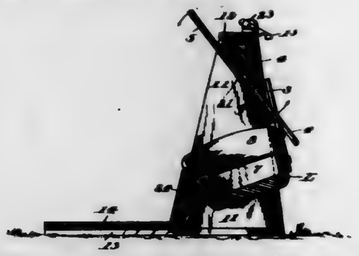
5. A covering for demijohns, comprising a shell, a lining for the same, a ring interposed between the lining and shell, a neck-band on the vessel, and a handle engaging the neck-band and the said ring, the handle having its lower portion formed with a hook hooking onto the ring, and the handle being bent inwardly over the ring, as set forth.

6. A covering for demijohns, comprising a shell, a lining for the same, the lower ends of the shell and lining extending over the outer portions

of the bottom of the vessel, an exterior flange on the said shell at the lower end thereof, a metallic ring held on the said flange, and prongs extending inwardly from the said ring to engage that portion of the covering held against the bottom of the vessel, as set forth.



705,896. FEED-TROUGH. JAMES W BARNES, Beaverton, Oreg. Filed Apr. 9, 1902. Serial No. 102'068. (No model.)



Claim.—1. A feed-trough comprising a trough hung upon pivots at the center of its ends so as to have a rotary adjustment, and a guard hung about pivots at the middle of its ends immediately above the trough, so as to be reversible, said trough and guard having locking devices cooperating with each other to hold the parts in their proper positions substantially as described.

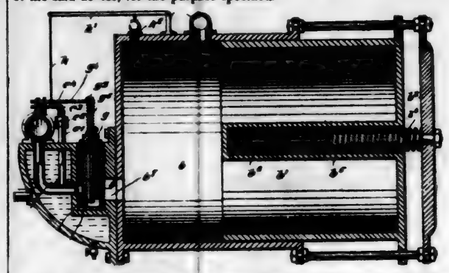
2. A feed-trough, comprising a trough hung about centers at its ends, so as to have a rotary adjustment, and having also a projecting arm acting as a manipulating-handle and also as a locking device, and a guard hung about centers at its ends above the trough and having a spring-latch engaging the locking-arm of the trough substantially as described.

3. A feed-trough, comprising a trough hung about centers at its ends so as to have a rotary adjustment and having also a projecting arm acting as a manipulating-handle and also as a locking device, a guard hung about centers at its ends above the trough and having a spring-latch engaging the locking-arm of the trough, upright end frames with a cross-bar at the top, and a gravity-catch on said cross-bar adapted to engage and hold the guard substantially as described.

4. A feed-trough comprising a platform 14 with sills 13, 13, upright end frames 11, 11, mounted thereon and having cross-bar 12 at the top and lower cross-bar 24 at the bottom next to the platform, a trough hung on a horizontal axis between the end frames, and a guard-board also hung between the end frames on a horizontal axis, and locking devices for holding the trough and guard in two positions as described.

705,897. MOTOR. ROBERT L. RARSHART, Charleroi, Pa. Filed June 3, 1901. Serial No. 62,961. (No model.)

Claim.—1. In an explosive-engine, the combination of a receiver for the fluid-pressure of the engine, a valve commanding the fuel-supply, a movable arm connected with the valve, a device for engaging the arm to actuate the valve, and means controlled by the fluid-pressure within the receiver, such means being capable of throwing the arm out of the path of the said device, for the purpose specified.



2. In an explosive-engine, the combination with a receiver for the fluid-pressure of the engine, of a valve commanding the fuel-supply, a swinging arm on the stem of the valve, a sliding actuating device for engaging the arm to operate it and thereby the valve, and means controlled by the fluid-pressure within the receiver for swinging the said arm out of the path of the sliding actuating device.

3. In an explosive-engine, the combination with a receiver, and a safety-valve therefor, of a valve for controlling the fuel-supply, an arm pivoted to the stem of the valve, means for operating the arm and thereby the valve, and a connection between the said arm and the safety-valve for swinging the arm into inactive position.

4. In an explosive-engine, the combination with the fuel-supply, and a spring-actuated valve therein provided with an arm extending from its stem, of a pump, and a pivoted dog connected with the pump-rod into the path of which the arm of the valve projects.

5. In an explosive-engine, the combination with the fuel-supply, and a spring-actuated valve therein, provided with an arm extending from its stem, of a pump, a slide on the pump-barrel and connected with the pump-rod, and a dog pivoted on the slide and into the path of which the arm of the valve projects.

6. In an explosive-engine, the combination with a receiver of a valve-chamber communicating with the receiver, a spring-actuated hollow valve in valve-chamber, a fuel-supply in communication with the valve-chamber, a pump also in communication with the valve-chamber, and means whereby the valve will be opened by the pump.

7. In an explosive-engine, the combination with a receiver, of a valve-chamber communicating with the receiver, a hollow valve in the chamber, means for normally holding the valve closed, a pump connected with the valve-chamber, a fuel-supply connected with the pipe leading from the pump to the valve-chamber, and means for operating the valve from the pump.

8. In an explosive-engine, the combination with a receiver, of a valve-chamber communicating with the receiver, a pump, a pipe leading from the pump to the valve-chamber, a fuel-supply connected with the pipe leading from the pump to the valve-chamber, a hollow and spring-pressed valve in the valve-chamber and provided with ports adapted to register alternately with the port leading into the receiver and with the pipe leading from the pump, and means connected with the pump-rod for operating the said valve, as set forth.

9. In an explosive-engine, the combination with a receiver, of a valve-chamber communicating with the receiver, a valve in the chamber, means for normally holding the valve closed, a pump connected with the valve-chamber, a fuel-supply connected with the pipe leading from the pump to the valve-chamber, means for operating the valve from the pump, and an igniting device controlled by the said valve.

10. In an explosive-engine, the combination with a receiver, of a valve-chamber communicating with the receiver, a hollow valve in the chamber, means for normally holding the valve closed, a pump connected with the valve-chamber, a fuel-supply connected with the pipe leading from the pump to the valve-chamber, means for operating the valve from the pump, and an igniting device in the hollow valve and controlled by the movement of said valve.

11. In an explosive-engine, the combination with a receiver, of a valve-chamber communicating with the receiver, a valve in the chamber, means for normally holding the valve closed, a pump connected with the valve-chamber, a fuel-supply connected with the pipe leading from the pump to the valve-chamber, a valve in the fuel-supply, and means for operating the said valves from the pump.

12. In an explosive-engine, the combination with a receiver, of a valve-chamber communicating with the receiver, a valve in the chamber, means for normally holding the valve closed, a pump connected with the valve-chamber, a fuel-supply connected with the pipe leading from the pump to the valve-chamber, means for holding the valve closed, means for operating the said valves from the pump, and an igniting device controlled by the first-named valve.

13. In an explosive-engine, the combination with a receiver, of a valve-chamber communicating with the receiver, a hollow valve in the chamber, means for normally holding the valve closed, a pump connected with the valve-chamber, a fuel-supply connected with the pipe leading from the pump to the valve-chamber, a valve in the fuel-supply, means for holding the valve closed, means for operating the said valves from the pump, and an igniting device in the valve and controlled by the same.

14. In an explosive-engine, the combination with a receiver, of a valve-chamber communicating with the receiver, a spring-actuated valve in the chamber and provided with an arm on its stem, a pump connected with the valve-chamber, a fuel-supply connected with the pipe leading from the pump to the valve-chamber, a spring-actuated valve in the fuel-supply and provided with an arm on its stem, a slide connected with the pump-rod, and pivoted dogs on the slide and adapted to engage the arms of the said valves.

15. In an explosive-engine, the combination with a receiver, of a valve-chamber communicating with the receiver, a normally closed valve in the chamber and provided with an arm on its stem, a pump connected with the valve-chamber, a fuel-supply connected with the pipe leading from the pump to the valve-chamber, a normally closed valve in the fuel-supply and provided with an arm on its stem, a slide connected with the pump-rod, pivoted dogs on the slide and adapted to engage the arms of the said valves, and an igniting device controlled by the first-named valve.

16. In an explosive-engine, the combination with a receiver, of a valve-chamber communicating with the receiver, a spring-actuated hollow rotating valve in the chamber and provided with an arm on its stem, a pump connected with the valve-chamber, a fuel-supply connected with the pipe leading from the pump to the valve-chamber, a spring-actuated valve in the fuel-supply and provided with an arm on its stem, a slide connected with the pump-rod, pivoted dogs on the slide and adapted to engage the arms of the said valves, and an igniting device in the hollow valve and controlled by the movement of said valve.

17. In an explosive-engine, the combination with a receiver, and a safety-valve therefor, of a fuel-supply, a valve therein, provided with a pivoted arm on its stem, means for engaging said arm to operate the valve, a pivoted lever operated by the safety-valve, and a flexible connection between the lever and arm of the valve.

18. In an explosive-engine, the combination with a receiver, and a safety-valve therefor, of a pump, a fuel-supply, a valve therein, means for operating the valve from the pump, and means for controlling the operation of the said valve from the safety-valve.

19. In an explosive-engine, the combination with a receiver, and a safety-valve therefor, of a pump, a fuel-supply, a valve in the fuel-supply and provided with a pivoted arm on its stem, means carried by the pump-rod for engaging the arm of the valve-stem to operate the valve, and means whereby the arm of the valve-stem will be raised into inoperative position from the safety-valve.

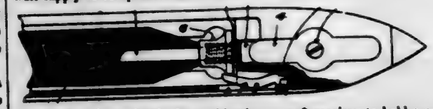
20. A motor, comprising an expanding receiver, a motor proper with which the receiver communicates, a valve-chamber communicating with the receiver, a valve in the valve-chamber, a pump in communication with the valve-chamber, a fuel-supply also in communication with the valve-chamber, a fuel-supply connected with the pipe leading from the pump to the valve-chamber, means for operating the valves from the pump, and an igniting device controlled by the first-named valve.

21. A motor, comprising an expanding receiver, a motor proper with which the receiver communicates, a valve-chamber communicating with the receiver, a hollow valve in the chamber, a pump in communication with the valve-chamber, a fuel-supply also in communication with the said valve-chamber, a valve in the fuel-supply, means for operating the valves from the pump, and an igniting device in the hollow valve and controlled by the movement thereof.

22. A motor comprising an expanding receiver having a safety-valve, a motor proper in communication with the receiver, a valve-chamber communicating with the receiver, a hollow rotating valve in the chamber, a pump in communication with the valve-chamber, a fuel-supply also in communication with the valve-chamber, a valve in the fuel-supply, means for operating the valves from the pump, means for controlling the operation of the valve in the fuel-supply from the safety-valve of the receiver, and an igniting device in the hollow valve and controlled by the movement thereof.

705,898. LOOM-SHUTTLE. HENRY BARNSLEY, Providence, R. I., assignor to Crompton & Knowles Loom Works, Worcester, Mass., a Corporation of Massachusetts. Filed Nov. 18, 1901. Serial No. 82,617. (No model.)

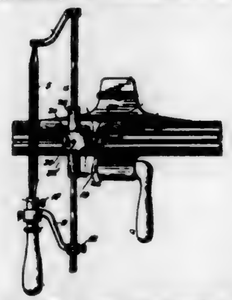
Claim.—1. In a loom-shuttle, in combination, the receiver for the working weft-supply, a follower mounted to move in the direction of the length of the weft-receiver and controlled as to such movement by the mass of yarn constituting the said weft-supply, and a movable trip or controller held in abnormal position by the said follower and released to assume its normal position by the movement of the follower lengthwise of the weft-receiver, which is permitted by depletion of the said working weft-supply to the predetermined extent.



2. In a loom-shuttle, in combination, a weft-receiver to hold a cop of weft or filling, a spring-actuated follower to coact with the base of the said cop, movable lengthwise of the said weft-receiver, and adapted to be held in an abnormal position by the said base, and a trip or controller movably connected with the shuttle-body, having an engaging portion adapted to occupy a position in which to coöperate with outside instrumentalities, the said follower engaging with the said trip or controller to hold the latter in abnormal position until permitted by the unwinding of the cop to become disengaged from the trip or controller.

3. In a loom-shuttle, in combination, the spindle, the follower applied thereto, the spring acting in connection with the said follower to press the same against a cop of weft or filling on the said spindle, and the spring-actuated trip or controller engaged by the said follower and thereby held in an abnormal position, the said trip or controller moving into its normal position when by the unwinding of the cop the follower is permitted to release the same.

705,899. SAW-FILING DEVICE. ANDREAS J. BOSE, Williamsport, Pa. Filed Nov. 27, 1901. Serial No. 83,205. (No model.)



Claim.—In a saw-filing device, the combination with a saw-clamp and a file-holder having a guide-rod; of a slide adjustable longitudinally on the clamp and provided with a bracket having a bearing, a yoke in which the guide-rod of the holder is slidably mounted, said yoke being provided with a pivot-opening and an arc-slot, a yoke-carrier having opened ears forming a guide to receive the yoke and provided with a trunnion journaled in said bearing, said trunnion having at one end a collar engaging one end of the bearing to hold it against longitudinal movement in one direction, and an annular series of seats, a washer secured to the trunnion and engaging the other end of the bearing to hold the trunnion against longitudinal movement in the opposite direction, a set-screw upon the bearing to engage the seats in the trunnion to secure it in adjusted position against rotation, a pivot-pin passing through the pivot-opening in the yoke and pivotally connecting the same to the ears of the bracket, and an adjusting-screw passing through the arc-slot in the yoke and adapted to draw the ears together to clamp the yoke, substantially as specified.

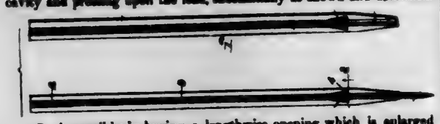
705,900. LEAD-PENCIL. LEO C. REISTS, Philadelphia, Pa. Filed Dec. 27, 1901. Serial No. 87,420. (No model.)

Claim.—1. A pencil-body having a lengthwise opening provided near the point with an enlargement forming a socket which is tapered upward, and a rubber band fitted in said socket, as shown and described.

2. A pencil-body having a lengthwise opening which is enlarged near the point and formed with a flat base and upward taper, and a lead, and encircling elastic band arranged in the enlargement of the opening, substantially as shown and described.

3. A pencil comprising a body having a lengthwise opening which is enlarged at one point and tapered upward, and an elastic piece held in the enlargement of the opening and adapted to bear upon a slidable lead, as shown and described.

4. A pencil comprising a body having a lengthwise opening which is enlarged near the point, to form a cavity having a flat base and tapered upward from such base, and a lead and elastic piece fitted in such cavity and pressing upon the lead, substantially as shown and described.

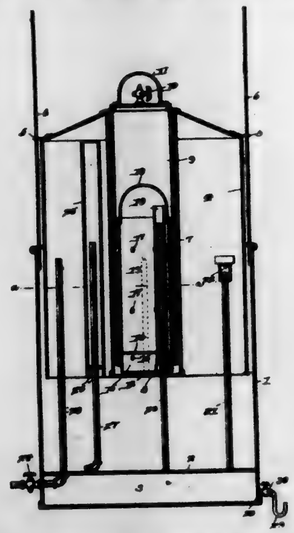


5. A pencil-body having a lengthwise opening which is enlarged near the point, to form a cavity having a flat base and tapered upward from such base, and adapted for reception of an elastic lead-detainer, as shown and described.

705,901. BUGGY-TOP RAISER. MORGAN BROWN, Lilley, Ga. Filed Nov. 12, 1901. Serial No. 82,004. (No model.)

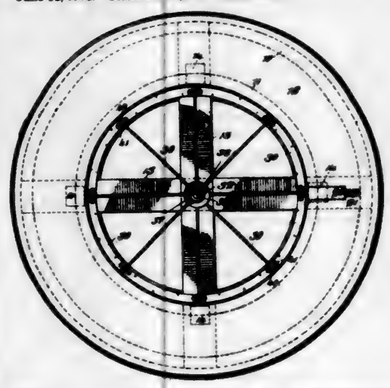
Claim.—The combination with a vehicle-top and the rear knuckle-braces thereof, of a rock-shaft, handles, clamps each comprising two plates having converging channels and a clamping-bolt engaged through the plates said plates being disposed with their corresponding channels in registration, with a knuckle-brace and a handle thereon respectively, bearings for the shaft secured to the vehicle and comprising movable members and bolts for holding them in position, and helical springs wound upon the shaft and each having its ends respectively clamped beneath the heads of the bolts of the clamps and bearings.

705,902. ACETYLENE-GAS GENERATOR. HERBERT L. BOOE, Walnutridge, Ark. Filed July 11, 1900. Serial No. 23,264. (No model.)



Claim.—The combination in an acetylene-gas generater, of the water-tank 1, a bell 4 having a centrally-disposed open-top cylinder 7, a perforated bottom for said cylinder, an open-bottom generating vessel 9 situated within said cylinder and having a handle 11, a U-shaped strap 12 having its ends pivotally connected to the opposite sides of the vessel and resting on the perforated bottom of the cylinder and supporting said vessel at a distance above said bottom, a carbid vessel in said generating vessel, said carbid vessel being supported on said strap and removable with the generating vessel from the apparatus, said strap serving as a means for readily detaching the carbid vessel from the generating-chamber, substantially as specified.

705,908. TABLE. GEORGE H. BULLOCK, Wakefield, R. I. Filed June 18, 1901. Serial No. 65,094. (No model.)



Claim.—1. A table, comprising a circular stationary outer section having a central opening and provided with feet and with bars on its bottom portion, extending across said central opening, a circular track secured upon the said bars at the margin of said opening, a socket-block secured to the cross-bars at the center thereof, an adjustable screw mounted in the block and having a recessed upper end, a hub mounted to turn on the socket-block and provided with radial arms, wheels at the outer ends of the arms, and a circular central revoluble section provided with a conical block at its center fitting in the recess of the screw and with a circular track on its lower face at the margin thereof, as set forth.

2. A table, comprising a circular stationary outer section having a central opening and provided with feet and with bars extending across the central opening, a circular track secured upon the bars at the margin of the opening, an adjustable support carried by the said bars at the center of the opening, a hub mounted to revolve around the support and provided with radial arms carrying wheels at their outer ends, and a revoluble circular inner section mounted upon the said support, within the opening of the stationary section and provided with a marginal rib at its upper edge extending over the stationary section and with a circular track on its lower face at the margin thereof, as set forth.

3. In a table, an outer stationary marginal section provided with legs one of which is provided with a longitudinal bore whose lower end is enlarged, and with a slot leading into said enlarged end of the bore, a revoluble central section, a brake mounted to slide in the stationary section, a spring for holding the brake retracted, a cord or chain secured to the brake and extending down into the bore of the leg, and a block secured to the lower end of the cord, said block being arranged in the enlargement of the bore of the leg and provided with a pin projecting out through the slot of the leg, as set forth.

4. A table, comprising a circular stationary outer section having a central opening and provided with feet and with bars extending across said opening, a circular track secured upon the bars at the margin of the opening, an adjustable support carried by the said bars at the center of the opening, a hub mounted to revolve around the support and provided with radial arms carrying wheels at their outer ends, a revoluble central circular section mounted in the opening upon the support and provided with a circular track on its lower face at the margin thereof, and a sliding brake mounted in the stationary section and adapted to engage the periphery of the revoluble section, as set forth.

5. A table, comprising a circular stationary outer section having a central opening and provided with feet and with bars crossing the central opening, a circular track carried by the cross-bars at the margin of the opening, an adjustable bearing carried by the said bars at the center of the opening, and having a socket in its end, a hub mounted to revolve around the bearing and provided with radial arms carrying wheels at their ends, a revoluble central section provided with a conical block at its center fitting in the socket of the bearing and provided with a bar on its under face at the margin, and a circular track secured to said bar, as set forth.

6. In a table the combination with a stationary outer section having a central opening and provided with an annular track at the margin of the opening, and a revoluble central section provided with an annular track on its under marginal surface, and with a conical block at its center, of a socket-block at the center of the stationary section, a screw screwing into said block and having a conical socket in its end receiving the conical block of the revoluble section, a hub mounted to revolve on the socket-block, and provided with radial arms, and wheels mounted on the outer ends of the said arms and traveling on the tracks, as set forth.

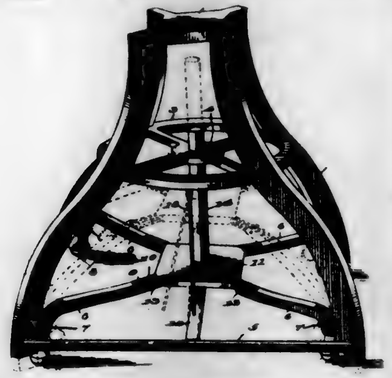
7. In a table, the combination with a stationary marginal section having a recess in its under face, and a revoluble central section mounted in the space inclosed by the outer section, of a sliding brake mounted in the recess of the stationary section and adapted to engage the periphery of the revoluble section, a spring for holding the brake out of engagement with the revoluble section, and a cord having one end secured to the brake and its other end provided with means to be engaged by the foot of the occupant of the table to operate the brake, as set forth.

705,904. DESULFURIZING OF SULFID ORES PREPARATORY TO SMELTING. ARCHIBALD D. CARMICHAEL, Broken Hill, New South Wales, Australia. Filed Nov. 11, 1901. Serial No. 81,941. (No specimens.)

Claim.—1. The process of treating mixed sulfid ores, which consists in mixing with said ores a sulfur compound of a metal of the alkaline earths, starting the reaction by heating the same, thereby oxidizing the sulfid and reducing the sulfur compound of the alkali metal, passing a current of air to oxidize the reduced sulfur compound of the metal of the alkalies preparatory to acting upon a new charge of sulfid ores, substantially as and for the purpose set forth.

2. The process of treating mixed sulfid ores, which consists in mixing calcium sulfate with said ores, starting the reaction by means of heat, thereby oxidizing the sulfid ores, liberating sulfurous-acid gas and converting the calcium sulfate into calcium sulfid and oxidizing the calcium sulfid to sulfate preparatory to treating a fresh charge of sulfid ores, substantially as and for the purpose set forth.

705,905. ELEVATING ROLLER ATTACHMENT. ALBERT H. CENTNER, Chicago, Ill. Filed Mar. 14, 1902. Serial No. 98,312. (No model.)



Claim.—1. An elevating roller attachment of the class set forth comprising a series of uprights connected to an upper bed, a series of levers movably connected to the inner portions of the uprights and having depending feet with rollers thereon, a central, movable device to which the said levers are attached, and a treadle connected to said movable device for throwing the rollers of the levers into operative position.

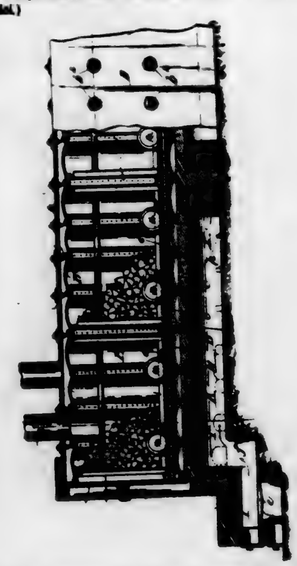
2. An elevating roller attachment comprising upright devices having levers movably connected thereto, the said levers being provided with depending feet having rollers thereon, and centrally-located means for operating the levers and throwing the rollers thereof below the lower ends of the said devices.

3. An elevating roller attachment of the class set forth comprising a series of upright supporting devices, levers movably attached to the inner portions of said devices and provided with outer depending feet having rollers thereon, central operating mechanism connected to said levers for throwing the rollers of the latter below the lower ends of the upright supporting devices, and means for locking the said central operating mechanism against movement when the rollers on the levers are depressed.

4. An elevating roller attachment of the class set forth, comprising a series of uprights, levers attached to the inner, lower portions thereof and provided with outer depending feet having rollers thereon, a spider horizontally disposed and connected to the uprights above the plane of the levers, a central table attached at opposite points to the levers and provided with an upwardly-projecting spindle movable through the spider, and a treadle attached to the table for lowering the latter and throwing the rollers on the levers into operative position.

5. An elevating roller attachment of the class set forth, comprising a series of uprights, levers attached to the inner, lower portions thereof and provided with outer depending feet having rollers thereon, a spider horizontally disposed and connected to the uprights above the plane of the levers, a central table attached at opposite points to the levers and provided with an upwardly-projecting spindle movable through the spider, a treadle attached to the table for lowering the latter and throwing the rollers on the levers into operative position, and a locking-rod loosely depending from the spider and adapted to engage the treadle.

705,906. RETORT FOR WOOD DISTILLATION. WILLIAM R. CHAPMAN, Boyne City, Mich. Filed Mar. 17, 1902. Serial No. 98,569. (No model.)



Claim.—1. A retort made of a series of separate plates said plates being bent or corrugated in direction transverse to the longitudinal axis of the retort substantially as described.

2. A retort consisting of a transversely-corrugated shell having its top and bottom and side walls made in separate plates, and continuous angle-bars arranged longitudinally to the retort along the corners for uniting said plates substantially as described.

3. A retort having corrugated sides combined in fixed relation with an outer casing of masonry and forming between said masonry casing and the corrugated plates closed flues for the passage of smoke and the products of combustion, each corrugation having its edges joined to the masonry walls to completely shut off the connection between the flue which it helps to form and the flues adjoining, whereby each flue is made capable of being opened or closed independently of the flue adjoining, substantially as described.

4. A retort made of sheet-metal plates corrugated transversely to the longitudinal axis of the retort, combined with an inclosing casing and anchors connecting the joints between the plates fixedly to the inclosing casing substantially as described.

5. A retort constructed as a sheet-metal shell corrugated transversely, rails laid longitudinally on the bottom of the retort, and supporting blocks or chairs for the rails between the corrugations of the bottom of the retort substantially as and for the purpose described.

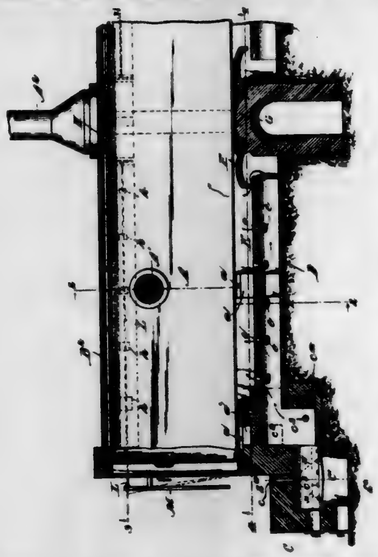
6. The combination with a retort corrugated transversely; of an inclosing casing forming smoke-flues between the same and the corrugated retort, and a subjacent furnace with central and side fires, opening into

each other at the end remote from the furnace, and passage-ways opening from the side flues into the space between the retort and casing, said passage-ways increasing in size toward the more remote point of travel substantially as described.

7. The combination with a retort corrugated on all four sides transversely, an inclosing casing of masonry leaving a free space all around the corrugated retort, and a subjacent furnace with flues communicating with the free space substantially as described.

8. In a retort of the kind described, the combination with an exterior wall; of an inner sheet-metal shell composed of separate plates corrugated transversely to the retort and riveted together in transverse seams, an angle-iron outside the shell having one flange retained by the rivets, a tie-bolt secured to the other flange of the angle-iron and extended to the exterior of the incasing wall, and a washer or clamp-plate secured to the outer end of the tie-bolt substantially as described.

705,907. FURNACE FOR RETORTS. WILLIAM B. CHAPMAN, Boyne City, Mich. Filed Mar. 17, 1902. Serial No. 98,570. (No model.)



Claim.—1. A furnace for a retort comprising a fire-box extending beyond the end of the retort and having a feed-hole for fuel in the top of the same and a fire-flue communicating with the said fire-box extending longitudinally beneath the retort on a higher level than the fire-box and having interposed between the retort and said flue a perforated distributing-partition substantially as shown and described.

2. A furnace for a retort comprising a fire-box extending beyond the end of the retort and having a feed-hole for fuel in the top of the same, and a fire-flue communicating with the said fire-box and extending longitudinally beneath the retort on a higher level than the fire-box, a perforated arch covering said flue and extending to a point near the middle of the retort, and an overhanging deflector-plate at the inner end of said arch substantially as described.

3. The combination with two retorts; of the two outside walls and the middle partition-wall between the retorts, the partition-wall having exit-flues built in its top, and independent furnaces and hot-air flues located beneath each retort substantially as described.

4. The combination with the two retorts and their outer inclosing walls and furnaces; of a middle partition-wall having two horizontal flues built in the top of the same and opening into the space about the retorts, dampers controlling said flues, pull-rods attached to the dampers and extending to the ends of the retorts, and levers connected to said pull-rods substantially as and for the purpose described.

5. The combination with the two retorts, and their outer inclosing walls, and furnaces; of a middle partition-wall having two horizontal flues built in the top of the same and opening at their ends into the smoke-stack and along their sides into the space about the retorts through holes increasing in size away from the smoke-stack substantially as and for the purpose described.

6. The combination with two retorts, and their outer inclosing walls and furnaces; of a middle partition-wall having two horizontal flues built in the top of the same with a common chamber H′ at the end opening into the smoke-stack and a series of holes in the sides opening into the spaces about the retorts, a damper-frame with hinged dampers set in the chamber H′ at the ends of the flues, and pull-rods extending through said flues to the front of the furnace and provided with means for working the same substantially as described.

7. A furnace for burning pulverulent or comminuted material, comprising a fire-box having its air-inlets above the grate-bars, said fire-box having a feed-hole for the comminuted fuel in the roof, and said roof being made as a low arch arranged in relation to the grate as described whereby the angle of repose of the pile of comminuted fuel fed through the roof onto the grate shall not cover up and obstruct the air-inlets above the grate-bars combined with a retort and its setting, said setting having a return longitudinal flue built below the retort with one end of the lower portion of said flue in communication with the furnace-chamber, and the other portion of the flue opening into the space about the retort substantially as and for the purpose described.

705,908. CUSHIONED HORSESHOE. PHILLIP J. COATES, Macon, Ga. Filed Feb. 13, 1902. Serial No. 93,916. (No model.)

Claim.—A horseshoe comprising a rubber body having a chamber open at top, flaps for closing said chamber, and a nailing and reinforcing plate removably seated in said chamber and concealed by said flaps, substantially as set forth.

705,909. TIME-STAMP. NORMAN COLLINS, London, England, assignor to the Empire Cash Register, Limited, London, England. Filed July 10, 1901. Serial No. 67,737. (No model.)

Claim.—1. In a time-stamp the combination of type-wheels respectively adapted to denote hours and tens and units of minutes; racks respectively in gear with said type-wheels for imparting rotary movement thereto; rock-levers for operating the respective racks; clock-driven snail-cams stepped to correspond respectively to hours and to tens and units of minutes of angular movement for determining the amplitudes of the oscillations of said levers; springs for moving said levers up to the respective cams; a hand-operated main shaft and mechanism actuated thereby adapted to normally hold the said levers out of contact with the said snail-cams and to permit by the revolution of said shaft the levers to be brought, by the respective springs, into operative contact with the said cams, for revolving the respective type-wheels to extents determined by the respective cams.

2. In a time-stamp the combination of a clock-driven stepped snail-cam; a rock-lever for coöperation with said cam; a pallet pivoted to said lever about an axis substantially in the plane of oscillation of the lever and coincident with the direction of motion thereof, for making unyielding contact with the periphery of said cam for the purpose of determining the amplitude of oscillation of the lever; and a spring adapted to normally hold the pallet in position to make such unyielding contact with the cam, and to permit the pallet to yield and be swung aside when caught by the cam in its rotary movement.

3. In a time-stamp, the combination of clock-driven snail-cams stepped to correspond respectively to units and tens of minutes of angular movement and rotated together as one; a spring connection between said cams and the hours-arbor of the clock, a detent for periodically engaging and detaining said cams in order to put the spring in tension, and means actuated by said arbor whereby to cause the detent to be withdrawn after a short interval of detention so as to permit the said cams to make under the stress of the spring a sudden angular advance, at the completion of every tenth of a revolution of the units-of-minutes cam.

4. In a time-stamp the combination of clock-driven snail-cams stepped to correspond respectively to units and tens of minutes of angular movement and rotated together as one; a spring connection between said cams and the hours-arbor of the clock, a detent for periodically engaging and detaining said cams in order to put the spring in tension, means actuated by said arbor for withdrawing the detent so as to permit the cams to make a sudden angular advance under the stress of the spring, a snail-cam stepped to correspond to hours of angular movement, a ratchet on said cam, a spring-actuated driving-pawl to engage said ratchet for actuating the hours-cam intermittently and suddenly and a snail-cam rotated by the hours-arbor of the clock for straining the driving-pawl spring and controlling its action, the operation of the hours-cam-propelment mechanism being coördinated with one of the sudden movements of the units and tens of minutes cams.

5. In a time-stamp, the combination with type-wheels, a printing-platen for taking impressions from said wheels and a hand-operated main shaft, of cam mechanism actuated at each revolution of said shaft and adapted to act on the platen so as to move the same toward the type by a sudden movement and consisting of a cam lever on an axis revolved at each revolution of the hand-shaft, a spring connected to said cam and axis so as to be wound up by the revolution of the hand-shaft when the cam is held stationary, a dog in connection with the cam, a cylinder-escapement geared with and rotated by said shaft and adapted to be engaged by the dog so as to cause the arrest of the cam and the winding of the spring during the first part of the revolution of said shaft, and adapted to permit the escape of the dog and the sudden revolution of the cam under the stress of the spring at a given point in the revolution of the shaft as described.

6. In a time-stamp the combination with type-wheels, a printing-platen for taking impressions from said wheels and a hand-operated main shaft, of cam mechanism actuated at each revolution of said shaft and adapted to act on the platen so as to move the same toward the type in two successive stages of relatively slow and sudden movement, said cam mechanism consisting of two rotary cams adapted to act successively on the platen, the cam for producing the slow movement being operated directly by the revolution of said shaft, and the other cam being connected to the said shaft through the medium of a spring adapted to be wound by the revolution of said shaft while the cam is held stationary, and being combined with a cylinder-escapement adapted to engage and retain the said cam and operated by said shaft so as to release the cam and permit it to act suddenly on the platen under the stress of the spring as described.

7. In a time-stamp, the combination with a cam-shaft and with clock-actuated type-wheel-setting mechanism adapted to be brought into operation by the rotation of said shaft, of cam-operated lever, pawl, and ratchet mechanism intermediate of said shaft and the spring-arbor of the clock-barrel and adapted to cause the clock-barrel spring to be rewound by the rotation of the said shaft at each rotation thereof.

8. In a time-stamp the combination with a cam-shaft, and with clock-actuated type-wheel-setting mechanism adapted to be brought into operation by the rotation of said shaft, of cam-operated lever, pawl, and ratchet mechanism adapted to rotate the spring-arbor of the clock-barrel and rewind the spring at each revolution of the shaft, and of safety mechanism for rendering the rewinding mechanism inoperative when the spring is fully wound, said safety mechanism comprising a cam adapted when in operative position to throw the driving-pawl out of engagement with the ratchet, and mechanism controlling the said cam, whereby the position of the said cam is determined by the mutually relative angular displacement of the spring-barrel and the spring-arbor.

9. In a time-stamp, the combination with a cam-shaft and with a clock-movement of lever, pawl, and ratchet mechanism operated by a cam on the said shaft, for rewinding the mainspring of the clock at each revolution of said shaft, of mechanism for rendering the rewinding mechanism inoperative when the spring is fully wound, said mechanism consisting of a cam adapted when in operative position to throw the driving-pawl out of engagement with the ratchet of the spring-arbor, a "hunting-gear" formed by a pair of star-wheels controlled by jumper-springs and adapted to be intermittently revolved by the barrel and by the spring-arbor respectively, cam-studs rotating with the star-wheels and adapted, when said cam-studs coincide in angular position, to cause displacement of one of the star-wheels in the direction of its axis, and means intermediate of said star-wheel and the driving-pawl-disengaging cam, whereby the position of said cam will be determined by the mutually relative angular displacements of the said star-wheels.

705,910. EARTH OR ROCK DRILL. FERDINAND H. DANNHARDT, South Yarra, near Melbourne, Victoria, Australia, assignor of two-thirds to Mahren Muller, North Carlton, near Melbourne, Victoria, Australia. Filed Sept. 29, 1900. Serial No. 31,507. (No model.)

Claim.—1. In an earth or rock drill, a cutter or tool carrier, laterally-operating sliding bolts arranged therein, a key-plate having pairs of oppositely and vertically extending inclined surfaces, the inclined surfaces of each pair being substantially parallel to one another, the said pairs of inclined surfaces adapted to alternately operate the said bolts laterally in opposite directions, and a weight connected to said key-plate.

2. In an earth or rock drill, the combination with the boring-rods or lining-tubes provided with recesses, of a cutter or tool carrier operating in said boring-rods or lining-tubes, cutters suitably connected to said carrier, laterally-operating sliding bolts adapted to extend through said carrier and engage in said recesses for connecting the carrier to the rods or lining-tubes, and a key-plate for expanding said cutters and having two pairs of oppositely-extending and substantially parallel inclined surfaces, said key-plate operating between said bolts for actuating them by means of said inclined surfaces.

3. In an earth or rock drill, the combination with the boring-rods or lining-tubes, of a cutter or tool carrier operating therein, cutters suitably connected to said carrier, sliding bolts adapted to extend through said carrier and engage the said rods or tubes for connecting the former to the latter, a key-plate having two pairs of oppositely-extending inclined surfaces and operating between said bolts and cutters for actuating the same, a tube connected to said plate and provided with outlets, a weight attached to said tube, and means connected to said weight for elevating and lowering said plate.

4. In an earth or rock drill, a cutter-carrier, bolts arranged therein, a key-plate provided with pairs of inclined surfaces for operating said bolts to connect and disconnect the cutter-carrier to and from the boring-rods or lining-tubes, a core-barrel extending downwardly from said cutter-carrier, a casing arranged in said core-barrel, a pair of hooks connected with said casing, and means for connecting said hooks with the said key-plate.

5. In an earth or rock drill, a cutter-carrier, expansible cutters suitably attached thereto, means for simultaneously actuating said cutters and for connecting said carrier to the boring-rods or lining-tubes, a core-barrel extending downwardly from said carrier, a casing within said barrel, an externally-screw-threaded sleeve connected to said barrel, a series of boring-tools engaging the screw-threads of said sleeve, and an outer sleeve engaging said sleeve and boring-tools for securing the latter in position.

6. In an earth or rock drill, a core-barrel provided with an eccentric recess, an inner casing for said barrel, a spring-actuated eccentric ring mounted in said recess, means for retaining said ring in an inoperative position, a sleeve connected to said barrel, a series of boring-tools engaging said sleeve, and an outer sleeve engaging said sleeve and tools for securing the latter in position.

7. In an earth or rock drill, a core-barrel provided with an eccentric recess, an inner casing suitably connected therein, a spring-actuated eccen-

tric ring mounted in said recess, means for retaining said ring in an inoperative position, and a series of boring-tools connected with said barrel.

8. In an earth or rock drill, a cutter-carrier, laterally-operating means for connecting the cutter-carrier to the boring-rods or lining-tubes, expansible cutters suitably connected to said carrier, a key-plate for expanding the cutters and provided with inclined surfaces extending parallel to one another for operating the lateral connecting means, a core-barrel extending downwardly from said expansible cutter-carrier, an inner casing suitably connected thereto, a spring-actuated eccentric ring suitably mounted in said core-barrel, means for retaining said ring in an inoperative position, a series of adjustable boring tools connected with said barrel, and a spring-clip suitably connected with the means for expanding the cutters and operating the lateral connecting means.

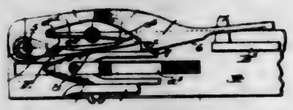
9. In an earth or rock drill, a cutter or tool carrier, cutters connected thereto, bolts arranged in said carrier and adapted when operated to extend through the cutters and engage in the boring-rods or lining-tubes for connecting the carrier thereto, and a weighted key-plate having two pairs of oppositely and vertically extending inclined surfaces adapted to engage and operate said bolts and cutters in opposite directions.

10. In an earth or rock drill, a cutter or tool carrier, cutters attached thereto, bolts arranged in said carrier and adapted to operate the same and engage in the boring-rods or lining-tubes for connecting the carrier thereto, a key-plate having two pairs of oppositely and vertically extending inclined surfaces operating between said bolts and cutters for connecting them in either direction, and vertically-operating means for operating said plate to release the bolts and for elevating said carrier independently of the boring-rods or lining-tubes.

11. In an earth or rock drill, a cutter-carrier having waterways or passages, cutters connected to said carrier, means arranged in the said carrier and adapted when operated to extend therethrough and engage in the boring-rods or lining-tubes for connecting the carrier thereto, and a key-plate provided with two pairs of oppositely and vertically extending inclined surfaces adapted to engage said means and said cutters for operating them.

12. In an earth or rock drill, a cutter-carrier, means carried thereby and adapted to extend therethrough for connecting said carrier to the boring-rods or lining-tubes, cutters suitably connected to the carrier, a key-plate provided with two pairs of oppositely and vertically extending inclined surfaces for actuating said means and cutters in either direction, a core-barrel suitably connected to the said key-plate, and a series of boring-tools suitably connected with said barrel.

705,911. SHUTTLE-CHECKING MECHANISM FOR LOOMS. CLARE H. DRAPER, Hopedale, Mass., assignor to Draper Company, Hopedale, Mass., a Corporation of Maine. Filed Dec. 28, 1901. Serial No. 86,880. (No model.)



Claim.—1. In a shuttle-checking mechanism for looms, primary and secondary checking members, a controlling-spring for the latter, operatively connected with the primary member, movement of said member by impact of the shuttle increasing the tension of said spring proportionally to the force of the blow before engagement of the shuttle with the secondary checking member.

2. In shuttle-checking mechanism for looms, a binder, a controlling-spring therefor, and means governed by or through the shuttle on each incoming pick thereof to automatically adjust the tension of the spring in proportion to the shuttle-speed prior to engagement of the shuttle and binder.

3. In shuttle-checking mechanism for looms, a binder, a controlling-spring therefor, means actuated by impact of the shuttle to vary the tension of the spring proportionally to the shuttle speed prior to engagement of the shuttle and binder, and protector mechanism governed by or through said means.

4. In shuttle-checking mechanism for looms, primary and secondary binders, a controlling-spring for each, and a connection between the primary binder and the secondary-binder spring, to automatically adjust the tension of said spring in proportion to the force with which the shuttle engages the primary binder.

5. In shuttle-checking mechanism for looms, primary and secondary binders normally in the path of the shuttle, a controlling-spring for each binder, stops to limit inward movement of the binders, and a connection between the primary binder and the spring of the secondary binder, to adjust the tension of said spring proportionally to the force with which the shuttle engages the primary binder.

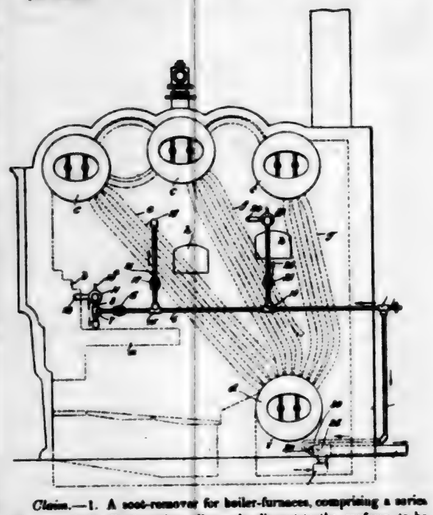
6. In shuttle-checking mechanism for looms, two binder members arranged in tandem, to successively engage the shuttle, a controlling-spring for the outermost member, and a connection between said spring and the innermost binder member, to set the tension of said spring, prior to engagement of to member with the shuttle, in proportion to the force with which the shuttle strikes the innermost of the binder members.

7. In shuttle-checking mechanism for looms, two binder members, a common fulcrum therefor, means to adjust the fulcrum, a spring controlling one of said binder members, and a connection between the other member and the spring, to adjust the tension of the latter, proportionally to the shuttle speed, by or through the engagement of the shuttle with the latter-mentioned binder member.

8. In shuttle-checking mechanism for looms, the combination of a primary binder, a spring therefor, a secondary binder, and a spring therefor, said primary binder acting as a stop for the secondary binder in its outward movement, whereby said secondary binder is checked in its outward movement by the successive action of both of said springs.

9. In shuttle-checking mechanism for looms, the combination of oscillatively-acting binders each pivoted to the lay, and a separate pressure-producing spring for each binder.

705,912. SOOT-CLEANER FOR STEAM-BOILERS. WILLIAM HOELSCHER, Windsor, Pa. Filed Dec. 3, 1901. Serial No. 84,510. (No model.)



Claim.—1. A soot-remover for boiler-furnaces, comprising a series of horizontal distributing-pipes disposed adjacent to the surfaces to be cleaned and within a boiler-furnace, each pipe provided with jet openings or nozzles, certain of said pipes being adjustable axially and disposed between adjacent surfaces which it is desired to clean, and means for supplying gaseous fluid under pressure to said distributing-pipes.

2. A soot-remover for boiler-furnaces, comprising a series of horizontal distributing-pipes disposed across a boiler-furnace and adjacent to the surface it is desired to clean, one or more of said pipes being adjustable axially and arranged to face toward two or more of the surfaces to be cleaned, a pipe for supplying gaseous fluid under pressure to all of the distributing pipes, valved branch pipes between the adjustable pipes and said supply-pipe, and swiveled couplings for uniting the adjustable pipes to said valved branch pipes.

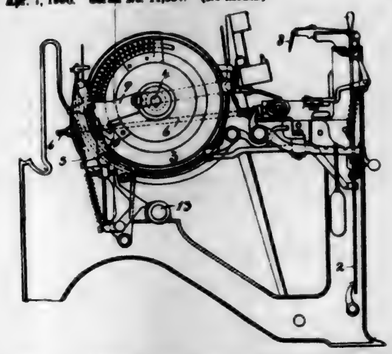
3. A soot-remover for boiler-furnaces, comprising a feed-pipe having branches, a horizontal distributing-pipe attached to one of the branches of the feed-pipe and disposed adjacent to a surface it is desired to clean, another distributing-pipe adapted to be adjusted on its axis and disposed parallel to the first-named pipe, and a swiveled coupling between the adjustable distributing-pipe and the other branch of said feed-pipe.

4. A soot-remover for boiler-furnaces, comprising a valved feed-pipe, a branch pipe connected to the end of said feed-pipe, an adjustable distributing-pipe coupled by a swiveled joint to one end of the branch pipe, another distributing-pipe made fast to the other end of said branch pipe, a series of valved branches extending from the feed-pipe, and other distributing-pipes united to said valved branches and disposed between and adjacent to other surfaces of the boiler which it is desired to clean.

5. A soot-remover for boiler-furnaces, comprising a horizontal collecting-pipe adapted to be arranged in the lower portion of a boiler-furnace and provided with a series of suction-nipples, a conveying-pipe leading from said collecting-pipe at a point between certain nipples of the series, and an injector arranged to discharge fluid under pressure into said conveying-pipe.

6. In a soot-remover for boiler-furnaces, the combination of a collecting-pipe having a plurality of suction-nipples, a conveying-pipe leading from the collecting-pipe, a feed-pipe adapted to supply steam or air under pressure, soot-removing pipes adapted to be disposed within a boiler-furnace and having communication with the feed-pipe, and an injector also communicating with the feed-pipe and arranged to deliver gaseous fluid under pressure to the conveying-pipe, substantially as described.

705,913. AUTOMATIC STOPPING MECHANISM FOR LOOMS. ABRAM D. ESTEY, Taunton, Mass., assignor to the Draper Company, Portland, Me., and Hopedale, Mass., a Corporation of Maine. Filed Apr. 7, 1900. Serial No. 11,987. (No model.)



Claim.—1. A loom having, in combination, a rotary abutment, a brake-wheel, a brake movable to and from said brake-wheel, a stop carried by and movable with said brake, and a cam which acts to move said stop into the path of said abutment after said brake has been applied.

2. A loom having, in combination, shipping mechanism, a brake controlled by said shipping mechanism, a stop which positively stops the motion of the parts of the loom affected by the shipping action of the shipping mechanism after the brake is applied, and a rebound-dog which limits the rebound of the said parts of the loom.

3. A loom having, in combination, shipping mechanism, a brake controlled by said shipping mechanism, an abutment on a moving part of the loom, a stop which positively encounters said abutment after the brake has acted, and a rebound-dog which limits the rebound of the moving parts of the loom controlled by the shipping mechanism.

4. A loom having, in combination, a rotary abutment, a brake, a spring-pressed rebound-dog on said brake, a stop on said brake, and shipping mechanism connected with said brake, whereby when the shipping mechanism acts the dog and stop are moved toward the path of said abutment.

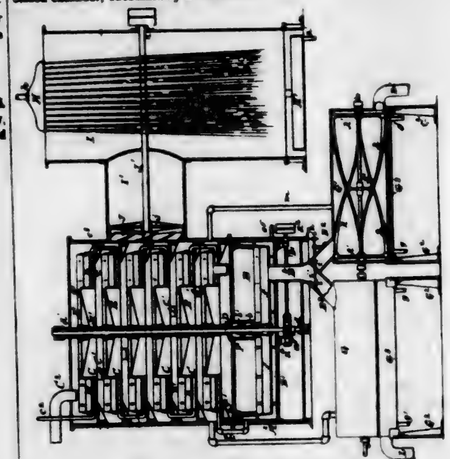
5. A loom having, in combination, a moving abutment, shipping mechanism, a cam or tappet, and a stop which is moved by the action of said shipping mechanism into the path of said cam or tappet, and is thereby moved into the path of said abutment.

6. A loom having, in combination, a moving abutment, shipping mechanism, and a rebound-dog which is moved by the action of the shipping mechanism into cooperative relation with said abutment.

7. A loom having, in combination, shipping mechanism, a moving cam or tappet, a moving spring-pressed abutment, a lever cooperatively connected with said shipping mechanism so that when said shipping mechanism acts it moves toward said abutment and a stop and a spring-pressed rebound-dog carried by said lever, the movement of said lever toward the abutment bringing said rebound-dog into the path of said abutment, and the said stop into cooperative relation to said cam or tappet, which thereupon moves said stop into the path of said abutment.

705,914. DRYING APPARATUS. JOHN C. FLEMING, New York, N. Y. Filed Jan. 12, 1901. Renewed Dec. 23, 1901. Serial No. 86,804. (No model.)

Claim.—1. The combination of a closed chamber having a series of annular troughs therein, one mounted above another, a pan in the lower portion of the chamber, a jacket for said pan, a steam-chamber under each of the troughs, a steam-supply pipe for said chambers and jacket, a driven shaft, blades carried by said shaft and arranged to travel in said troughs and the pan, a supply-pipe discharging material into the upper trough, outlet-openings in each trough, a pipe communicating with the pan, a comparatively large pipe forming an outlet from the closed chamber between the upper and lower troughs, a spider-like piece in said pipe, a shaft having a bearing in said piece, and an exhaust-fan on the said shaft in the pipe operating to draw the vapors from the body of the closed chamber, substantially as described.



2. The combination of a closed chamber having a series of annular troughs therein, one mounted above another, a pan in the lower portion of the casing, means for heating the troughs and the pan, means for carrying off the vapor, a finishing-receiver under the chamber and communicating with the pan, and a shaft running therethrough carrying curved blades for agitating the material in the receiver, substantially as described.

3. The combination of a closed chamber, a series of troughs therein, a pan in the lower portion of the chamber, means for conveying material in the troughs to the pan, means for carrying off the vapor, two finishing-receivers mounted below the chamber and communicating therewith, and a valve for directing the material from the pan into either one of the finishing-receivers, substantially as described.

4. The combination of a closed chamber, a series of troughs therein, means for conveying material in the troughs, one trough discharging into another, means for heating the material in the troughs, a fan for carrying off the vapors, two finishing-receivers communicating with the lowermost trough or pan, a valve for directing the material into either one or the other of the receivers, and agitating means in each receiver, substantially as described.

5. The combination of a closed chamber, a series of troughs therein, means for conveying material in the troughs, one trough discharging into another, means for heating the material in the troughs, a fan for carrying off the vapors, two finishing-receivers communicating with the lowermost trough or pan, a valve for directing the material into either one or the other of the receivers, agitating means in each receiver, and steam-jackets inclosing the lower portion of each receiver, substantially as described.

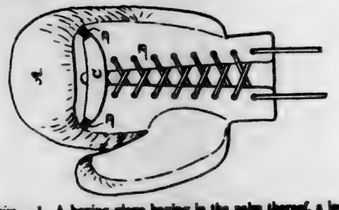
6. The combination of a closed chamber, a series of troughs therein, means for conveying material in the troughs, one trough discharging into another, means for heating the material in the troughs, a fan for carrying off the vapors, two finishing-receivers communicating with the lowermost trough or pan, a valve for directing the material into either one or the other of the receivers, agitating means in each receiver, steam-jackets inclosing the lower portion of each receiver, and pipes connecting each receiver with the closed chamber, substantially as described.

7. The combination of a closed chamber, a series of troughs, one arranged below another, a pan in the lower portion, a steam-chamber for the troughs and a steam-jacket for the pan, a vertical shaft, arms thereon having blades arranged to travel in the several troughs and pan, outlet-openings in each trough, a supply-pipe for the material to be treated, an outlet-pipe for the material, a condenser, a water-spray device in the same, a comparatively large pipe forming communication between the chamber and the condenser, a spider-like piece therein, a shaft having a bearing

in said piece, and an exhaust-fan on the shaft in said pipe, substantially as described.

8. The combination of a closed chamber, a series of troughs therein, one mounted above another, a steam-chamber under the bottom of each trough, a steam-supply pipe for the upper chamber and pipes communicating the several chambers, a pan under the troughs, a jacket for said pan communicating with the steam-chamber of the lowermost trough, a vertical shaft, blades on said shaft arranged to travel in the troughs, a pan, outlet-openings in each trough, a feed-pipe for the material so that material fed into the upper trough will pass from one trough to the other and into the pan, two finishing-receivers communicating with the pan, a valve for directing the flow of material into either one of the said receivers, agitating means in each receiver, outlets for the receivers, a condenser, a water-spray device therein, a pipe forming communication between the chamber and the condenser, and a suction-fan in said pipe so as to carry off the vapor as it is formed, substantially as described.

705,915. **BOXING-GLOVE.** JOHN GAMBLE, Philadelphia, Pa., assignor to George A. Roach, Philadelphia, Pa. Filed Dec. 18, 1901. Serial No. 86,328. (No model.)



Claim.—1. A boxing-glove having in the palm thereof, a longitudinal vent or opening, adapted to be drawn together by any suitable means, and an adjustable palm-grip extending loosely across the palm of the glove and having its ends secured to said glove.

2. As an article of manufacture, a boxing-glove having its inner or palm portion provided with a longitudinal vent or opening extending to a point approximately midway between the base of the fingers and the tips thereof, the sides of said opening being provided with closing means, whereby the glove may be adjusted to hands of different sizes, so as to closely inclose both the body of the hand and the fingers thereof.

3. As an article of manufacture, a boxing-glove having its inner or palm portion provided with a longitudinal opening or vent extending from the top of the glove to a point approximately midway between the base of the fingers and the tips thereof, said opening affording ventilation for the palm and fingers, and suitable lacing means for drawing the edges of the vent or opening together, so as to adapt the glove to be drawn snugly around the body and fingers of the hand whether it be broad or narrow.

4. A boxing-glove having a palm-grip secured at its respective ends to the glove, said palm-grip lying across the palm and being free to accommodate itself to the grip of different sizes or lengths of hands.

5. A boxing-glove having therein an adjustable palm-grip that extends loosely across the inside of the glove and is fastened thereto only at the ends of the grip, substantially as shown.

6. A boxing-glove having therein an adjustable palm-grip that extends loosely across the inside of the glove, and is secured thereto through an intermediate elastic portion at the two ends of the grip, substantially as shown.

7. A boxing-glove having an adjustable palm-grip that extends loosely across the inner portion of the glove, and is secured thereto by an elastic cord or connection that passes through the grip and is attached at the ends thereof to the sides of the glove, substantially as shown.

705,916. **BOTTLE-NIPPLE.** PHILIP GANS, New York, N. Y. Filed July 14, 1900. Serial No. 23,722. (No model.)

Claim.—A nursing-bottle nipple having a mouth piece provided with a straight cylindrical duct through it and reduced centrad, the said mouthpiece being oval in cross-section, the walls at the approximately flat sides being thinner than the walls at the other sides, whereby the thin walls will permit of slight yielding and the thicker walls will prevent collapsing.

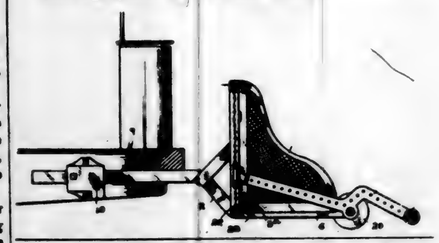
705,917. **SCREW-DRIVER.** GEORGE R. GAY, Augusta, Me. Filed Apr. 18, 1902. Serial No. 103,104. (No model.)

Claim.—1. A screw-driver comprising a ferrule, a blade mounted to rotate therein, ratchet-teeth on the inner end of said blade, a guide-pin extended transversely in the ferrule, a pawl having a slot through which said pin passes, whereby the pawl may swing on the pin and also move transversely thereof, and means for rocking the pawl to engage either of its ends with the ratchet-teeth, substantially as specified.

2. A screw-driver comprising a ferrule, a blade mounted to rotate therein and having ratchet-teeth on its inner end, said ferrule being provided with opposite slots, a pin extended transversely through the ferrule, a pawl extended across the ferrule and having a slot through which the pin passes, whereby the pawl may rock on the pin and also have a transverse movement with relation thereto, projections on said pawl passing through the slots of the ferrule, a sleeve mounted to rotate on the ferrule, and a cam on the inner side of said sleeve for rocking the pawl, substantially as specified.

3. A screw-driver comprising a ferrule, a blade mounted to rotate therein and having ratchet-teeth on its inner end, said ferrule being provided with opposite slots, a pin extended transversely through the ferrule, a pawl extended across the ferrule and having a slot through which the pin passes, whereby the pawl may rock on the pin and also have a transverse movement with relation thereto, projections on said pawl passing through the slots of the ferrule, a sleeve mounted to rotate on the ferrule, a cam on the inner side of said sleeve for rocking the pawl, and a stop-block engaging with the inner end of the blade, substantially as specified.

705,918. **CAR-FENDER.** CHARLES GIBLIN, Cleveland, Ohio. Filed Aug. 12, 1901. Serial No. 71,963. (No model.)



Claim.—1. The combination with a car, of bars secured thereto, supporting-arms carried by the bars, the sides and back of a cage detachably secured to the arms and bars, and a bottom pivotally mounted between the sides.

2. The combination with a car, of bars secured thereto, supporting-arms carried by the bars, the sides and back of a cage detachably secured to the arms and bars, a shaft carried by the bars, and a bottom pivotally mounted upon the shaft.

3. The combination with a car, of brackets secured thereto, bars secured to said brackets, and each having a downwardly-bent portion and a forwardly-extending arm, springs carried by said brackets to normally keep said arms elevated, the sides and back of a cage carried by said arms, a shaft carried by the forward ends of said arms, wheels carried by said shaft, and a bottom pivotally secured to said shaft.

4. The combination with a car, of brackets secured thereto, bars secured to said brackets to have a limited vertical movement, springs carried by said brackets to normally hold said bars elevated, the sides and back of a cage carried by said bars, a shaft journaled on said bars, wheels carried by said shaft, and a bottom pivoted upon said shaft.

5. The combination with a car, of bars secured thereto, supporting-arms carried by the bars, the sides and back of a cage detachably secured to the arms and bars, a shaft carried by the bars, a bottom pivotally mounted upon the shaft, and means carried by the sides and bottom to normally retain the bottom in an inclined plane.

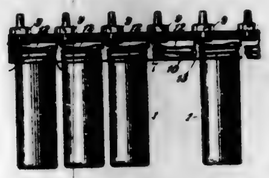
6. The combination with a car, of brackets secured thereto, bars secured to said brackets, and having downwardly-curved portions and forwardly-extending arms, supporting-arms secured to said downwardly-curved portions, sides and back of a cage, means for securing said sides and back together, means for securing said sides and back to the supporting and forwardly-extending arms respectively, eyes carried by said sides, a shaft journaled in said forwardly-extending arms, wheels carried by said shaft, a bottom pivotally mounted on said shaft, pins secured to said bottom to engage said eyes, springs interposed between said eyes and said bottom to hold said bottom normally inclined and an antifriction-roller secured to the front of said bottom.

7. The combination with a car, of bars secured thereto, supporting-arms carried by the bars, the sides and back of a cage detachably secured to the arms and bars, a shaft carried by the bars, a bottom pivotally mounted upon the shaft, eyes carried by the sides, means carried by the bottom and adapted to engage the eyes, and springs interposed between the eyes and bottom to normally retain the bottom in an inclined plane.

8. The combination with a car, of brackets secured thereto, springs carried by the brackets, bars secured to the brackets, supporting-arms carried by the bars, the sides and back of a cage detachably secured to the arms and bars, a shaft carried by the bars, wheels journaled upon the shaft, a bottom pivotally mounted upon the shaft, and means carried by the sides and bottom to normally retain the bottom inclined.

9. The combination with a car, of bars secured thereto, and having downwardly-bent portions and forwardly-extending arms, supporting-arms secured to the downwardly-bent portions, the sides and back of a cage detachably secured to the supporting and forwardly-extending arms, a shaft carried by the forwardly-extending arms, and a bottom pivotally mounted upon the shaft.

705,919. **ELECTRIC BATTERY.** EDWIN R. GILL, New York, N. Y. Filed Nov. 15, 1901. Serial No. 82,478. (No model.)



Claim.—1. As an article of manufacture, a battery-cell having an exterior screw-threaded electrode.

2. As an article of manufacture a battery-cell having a screw-threaded top in electrical connection with one electrode of said cell.

3. A screw-threaded socket, and a contact-spring therein; in combination with a battery-cell having threads adapted to screw into said socket.

4. A socket and two terminal pieces attached thereto, in combination with a battery-cell fitting said socket and having electrodes adapted to make contact with said socket-terminals respectively and means for securing said cell in said socket.

5. A socket and two terminal pieces attached thereto so constructed as to make contact when said socket is empty; in combination with a battery-cell fitting said socket and having electrodes adapted to make contact with said socket-terminals respectively and means for securing said cell in said socket.

6. A screw-threaded socket, a terminal spring therein and a second terminal upon which said spring normally bears; in combination with a screw-threaded battery-cell fitting said socket and having an electrode adapted to lift said spring-terminal off of said second terminal when said cell is screwed home in said socket.

7. A screw-threaded socket, a terminal at the side thereof and a terminal in the middle thereof; in combination with a battery-cell having an exterior electrode screw-threaded to fit said socket and an interior electrode so placed that when the cell is screwed home in said socket said interior electrode touches the terminal in the middle of the socket and the exterior electrode bears upon the terminal at the side of the socket.

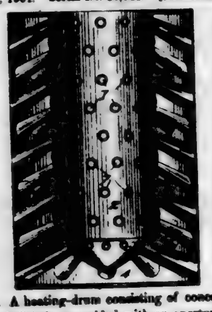
8. As an article of manufacture, an insulating battery-head provided with sockets for receiving cells, and a spring at each socket, said springs overlapping from one socket to the other and normally making contact each with its neighbor.

9. An insulating-head, screw-sockets thereon, a binding-post beside each socket and a two-leaved spring attached to said post, one leaf of which extends across one contiguous socket and the other leaf of which extends to the edge of the other contiguous socket; in combination with a battery-cell having an external screw-threaded electrode fitting said socket and adapted to touch one leaf of one adjacent contact-spring and an interior electrode adapted to touch one leaf of the other adjacent contact-spring.

705,920. **STRAIGHTENING-CASE FOR THE FINGER.** MARIE GOTTSCHALK, Berlin, Germany. Filed Jan. 3, 1902. Serial No. 88,264. (No model.)

Claim.—A straightening-case for the finger comprising a plate *a* of rigid material and suitable fastening devices *b* for affixing the said plate to the finger over the finger-joint, substantially as and for the purpose set forth.

705,921. **HEATING-DRUM.** EUPHEMIA GRAHAM, Carroll, Iowa. Filed Dec. 31, 1901. Serial No. 87,918. (No model.)



Claim.—1. A heating-drum consisting of concentric shells spaced apart, the outer shell being provided with an aperture at its lower end, and the inner shell being closed at its lower end and arranged immediately above said aperture, the upper ends of both of said shells being connected together by a ring to close the upper end of the chamber formed by the two shells, and open-ended tubes extending through said chamber and connected to said shells, substantially as set forth.

2. A heating-drum consisting of concentric shells spaced apart, the outer shell being provided with an aperture at its lower end and the inner shell having a closed conical lower end which is arranged immediately above said aperture, the upper ends of both of said shells being connected together by a ring which closes the upper end of the chamber formed by the two shells, and open-ended tubes extending through said chamber and connected to said shells, said tubes tapering from their outer to their inner ends at which latter point they are the smallest, substantially as set forth.

703,922. **WIND-MOTOR.** ALBERT GRAF, Chicago, Ill. Filed Nov 13, 1901 Serial No. 82,113. (No model.)

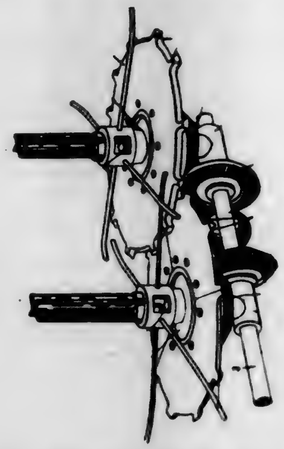
Claim.—1. A wind-motor, consisting of a frame mounted to turn, a wheel journaled in the frame, a chute for directing the wind to the wheel and comprising an inclined bottom extending upwardly and inwardly from the frame to within a short distance of the periphery of the wheel, and a top hinged to the frame and extending partially over the wheel, a bar pivoted to the top of the chute and provided with notches engaging the frame, a bracket secured to the frame and provided with a slot through which the bar passes, a pulley mounted in the bracket, and a rope passing loosely through an opening in the said bar and over said pulley, as set forth.

2. A wind-motor, comprising a frame mounted to turn, a wheel journaled in the frame, a chute for directing the wind to the wheel and comprising an inclined bottom extending upwardly and inwardly from the

outer edge of the frame to within a short distance of the periphery of the wheel, and a hinged top extending partially over the wheel, a bar hinged to the top and having notches engaging the frame, and a rope operatively connected with the said bar, as set forth.

3. In a wind-motor, the combination with a support, and a wheel mounted thereon, of a chute, comprising an imperforate inclined bottom extending to within a short distance of the periphery of the wheel at about the center thereof and a hinged top extending partially over the wheel, a bar hinged to the top and having an interlocking engagement with the said bottom, and means connected with the said bar for operating it, as set forth.

705,923. CUTTER FOR CORN-HARVESTERS. ARTHUR E. KAPLEY, Indianapolis, Ind. Filed Feb. 5, 1901. Serial No. 45,087. (No model.)



Claim.—1. As an article of manufacture, a disk cutter having a series of arms projecting from the periphery thereof, cutting edges formed upon the periphery of said disk, and the outer, forward, lower corner of each arm raised slightly above the plane of the cutting edge, substantially as described.

2. As an article of manufacture, a disk cutter having a series of arms projecting from the periphery thereof, cutting edges formed upon the periphery of said disk and upon the sides of said arms, and the lower corners of each arm raised slightly above the plane of the cutting edges, substantially as described.

705,924. APPARATUS FOR DEFECATING LIQUIDS. JAMES B. HAYNE, Santo Domingo, Santo Domingo. Filed Aug. 1, 1901. Serial No. 70,868. (No model.)

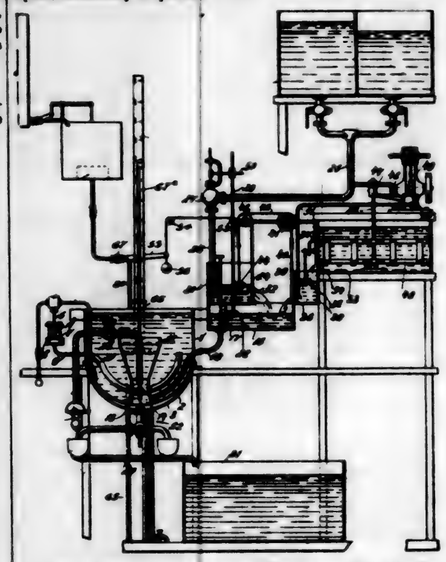
Claim.—1. In an apparatus for the defecation of liquids, a heating vessel, means for supplying heat thereto, a separator arranged within the vessel, a siphon leading from said separator, a supply-tank, and means for automatically controlling the supply of liquid from said tank to the heating vessel, substantially as specified.

2. An apparatus for the defecation of liquids, comprising a heating vessel, means for supplying a heating medium thereto, means for automatically controlling the supply of heating medium, a separator in the vessel, and an automatically-controlled siphon leading from said separator, substantially as specified.

3. An apparatus for the defecation of liquids, comprising a heating vessel, means for supplying a heating medium thereto, a supply vessel for supplying liquid to the heating vessel, a supply-pipe leading to the bottom of the heating vessel, an alkalinator-tank, and means for automatically controlling the supply of alkalizing medium to the liquid to be defecated, substantially as specified.

4. An apparatus for the defecation of liquids, comprising a heating vessel having a double bottom, a pipe for conveying the heating medium into the space between the bottoms, a pipe extended into the vessel and adapted to contain an expansive medium, a diaphragm arranged to receive the pressure of said expansive medium, a connection between said diaphragm and a valve in the heat-supply pipe, and a liquid-supply pipe leading into the vessel, substantially as specified.

5. An apparatus for the defecation of liquids, comprising a heating vessel, a separator arranged in the vessel and having a valve-controlled opening in its lower portion, a supply-pipe leading below the separator into the heating vessel, a siphon having one member extended into said separator and nearly to the bottom thereof, an automatically-controlled valve in said siphon, and a regulating-valve on the outer section of said siphon, substantially as specified.



6. An apparatus for the defecation of liquids, comprising a heating vessel, means for automatically controlling a supply of heating medium to the vessel, a supply-tank having communication with the vessel, a tank for controlling an alkalizing medium, and means for automatically controlling the supply therefrom, substantially as specified.

7. An apparatus for the defecation of liquids, comprising a heating vessel, means for supplying heat thereto, a supply-tank having communication with the heating vessel, a tank for containing an alkalizing medium, an aerating vessel for receiving the said agent from said tank, an air-compressor, and a pipe leading from said compressor into said aerating vessel, substantially as specified.

8. An apparatus for the defecation of liquids, comprising a supply-tank, a measuring-tank having a vertical partition leading nearly to the bottom thereof and also having a vertical outlet-slot in one of its walls, a pipe leading from the supply-tank into the receiving-tank rearward of the partition, an automatically-controlled valve in said pipe, a trough into which the receiving-tank discharges, a supply-tank for an alkalizing medium discharging into said trough, and a heating vessel receiving the liquid from said trough, substantially as specified.

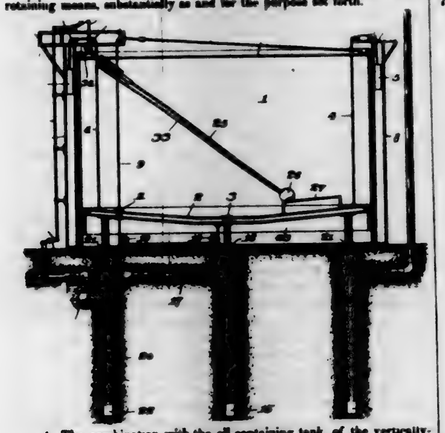
9. An apparatus for the defecation of liquids, comprising a heating vessel, a supply-tank having communication with said heating vessel, a tank for an alkalizing medium, means for automatically controlling the discharge of said medium from the tank, and a stirrer operating in the tank, substantially as specified.

705,925. APPARATUS FOR EXTINGUISHING FIRE IN OIL-TANKS OR THE LIKE. JOHN HARLSHORN, Philadelphia, Pa. Filed Oct. 19, 1901. Serial No. 79,254. (No model.)

Claim.—1. The combination with the oil-containing tank, the vertically-movable disk therein, devices for retaining the latter normally adjacent to the bottom of the tank, means for releasing said devices when required, and means adapted to automatically elevate said disk in the tank upon the release of said retaining devices, substantially as and for the purpose set forth.

2. The combination with the oil-containing tank, the vertically-movable disk therein, devices for retaining the latter normally adjacent to the bottom of the tank, means for releasing said devices when required, and means adapted to automatically elevate said disk in the tank upon the release of said retaining devices, together with the annulus adapted to be engaged by the said disk, substantially as and for the purpose set forth.

3. The combination with the oil-containing tank of the vertically-movable disk therein, the depending flange or skirt carried by the latter, means for retaining said disk normally adjacent to the bottom of the tank, and means for automatically elevating said disk upon the release of said retaining means, substantially as and for the purpose set forth.



4. The combination with the oil-containing tank, of the vertically-movable disk therein, means for retaining the latter normally adjacent to the bottom of the tank, which means are adapted to be released by the heat of burning oil within said tank, and means for elevating said disk automatically upon the release of said retaining devices, substantially as and for the purpose set forth.

5. The combination with the oil-containing tank, of the vertically-movable disk therein, the inwardly-projecting flange or annulus of said tank, an inflammable or fusible connection for retaining said disk normally adjacent to the bottom of the tank, and weights or the like, connected with said disk and adapted to elevate the latter in the tank upon the severance of said disk-retaining connection, substantially as and for the purpose set forth.

6. The combination with the oil-containing tank, of the vertically-movable dished disk therein, devices for retaining the latter normally adjacent to the bottom of the tank, means for elevating said disk upon the release of said retaining devices, the exit-pipe leading from the central portion of said disk, the normally closed valve connected with said pipe and adapted to be opened by the upward movement of said disk at the predetermined time excited, substantially as and for the purpose set forth.

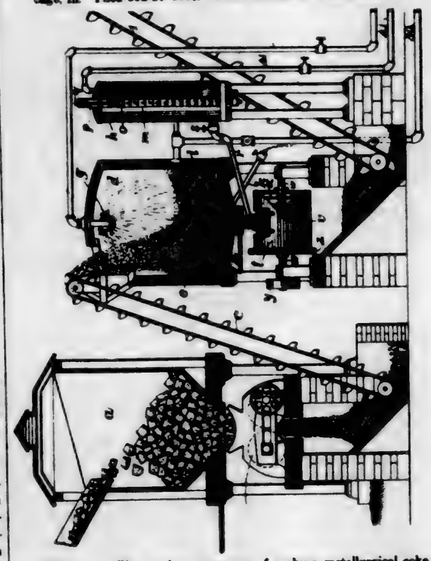
7. The combination with the oil-containing tank, of the vertically-movable hollow disk therein, means for charging the latter with water, devices for retaining said disk normally adjacent to the bottom of the tank, means for releasing said retaining devices when required, and means adapted to automatically elevate said disk upon the release of said retaining devices, substantially as and for the purpose set forth.

8. The combination with the oil-containing tank of the vertically-movable, hollow disk therein, the water inlet and outlet pipes communicating with the interior of said disk, devices for retaining the latter normally adjacent to the bottom of the tank, means for releasing said retaining devices when required, and means adapted to automatically elevate said disk upon the release of said retaining devices, substantially as and for the purpose set forth.

9. The combination with the oil-containing tank, of the vertically-movable disk therein, the annulus against which the latter is adapted to impinge, the connection comprising the chain or the like and the fusible ribbon, or the like, connected thereto and extending across the top of the tank, for maintaining the disk normally adjacent to the bottom of the tank, and means consisting of chains or the like connected to said disk and having weights adapted to draw up said disk when the said ribbon becomes fused from the heat of the burning oil within said tank, substantially as and for the purpose set forth.

10. The combination with the oil-containing tank, of the vertically-movable dished disk therein, devices for retaining said disk normally adjacent to the bottom of said tank, means for automatically elevating said disk upon the release of said retaining devices, the exit-pipe leading from the central part of said disk, the normally closed valve with which said pipe communicates, the pivoted bar having the float, the fusible ribbon or the like attached to said bar normally disconnecting devices between the latter and said valve, which devices are adapted to be connected upon the fusing of said ribbon, together with the projection of said disk adapted to impinge against said float when said disk is caused to move upwardly, substantially as and for the purpose set forth.

705,926. CONTINUOUS PROCESS OF COKING COAL. JOSEPH HEMINGWAY, Chicago, Ill., assignor of three-fourths to Curtis Joel Rothermel, Springvalley, Minn., and William Edwin Rothermel, Chicago, Ill. Filed Oct. 21, 1901. Serial No. 79,455. (No model.)



Claim.—1. The continuous process of making metallurgical coke, which consists in pulverizing bituminous or semibituminous coal, mixing it with about four per cent. of water and about ten per cent. of coal-tar, charging the coking-ovens with said mixture, and distilling it, substantially as described.

2. The continuous process of making metallurgical coke, which consists in pulverizing bituminous or semibituminous coal, mixing it with about four per cent. of boiling-hot water, mixing the moistened mass with about ten per cent. of coal-tar, charging the coking-ovens with said mixture, distilling it, and returning the heavy portion of the distillate containing tar, pitch and similar substances (mixed with a fresh charge of coal moistened with hot water) into the coking-ovens during the coking operation, substantially as described.

705,927. BRAKE-SHOE ADJUSTER. EDWIN M. HERR, Pittsburg, Pa., assignor to the Westinghouse Air Brake Company, Pittsburg, Pa., a Corporation of Pennsylvania. Filed Dec. 7, 1901. Serial No. 85,051. (No model.)

Claim.—1. The combination with a brake-shoe, of an adjustable support therefor, and means operated by the dragging movement of said shoe for adjusting said support.

2. The combination with a brake-shoe having an adjustable support, of another brake-shoe adapted to be applied by the dragging movement of the first shoe and means for automatically adjusting the said support to compensate for the wear of said shoe.

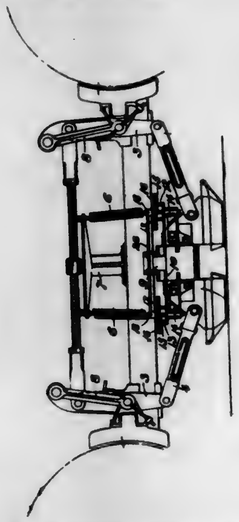
3. The combination with a brake-shoe having an adjustable support, of another brake-shoe adapted to be applied by the dragging movement of the first shoe when the car is moving in either direction, and means operated by the dragging movement for adjusting said support.

4. In a car-brake, the combination with a brake-shoe having an adjustable support and means for applying said shoe, of another brake-shoe and intermediate connections adapted to apply the second shoe by the dragging movement of the first shoe, and means operated by such movement for automatically adjusting said support when the first brake-shoe becomes worn.

5. In a car-brake, the combination with a magnetic brake-shoe having an adjustable support, of means for automatically adjusting said support to compensate for the wear of said shoe.

6. In a car-brake, the combination with a magnetic brake-shoe hav-

ing an adjustable spring-support, and means operated by the dragging movement of said shoe for adjusting said support.



7. In a car-brake, the combination of a brake-shoe, a support therefor having an adjustable screw to compensate for the wear of the shoe, and means operated by the dragging movement of said shoe for adjusting said screw.

8. In a car-brake, the combination of a brake-shoe, a support therefor having an adjustable screw, and fixed stops secured to the car-frame by which said screw may be rotated during the dragging movement of said shoe.

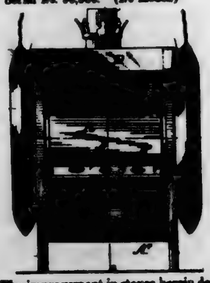
9. In a car-brake, the combination with a rail brake-shoe having an adjustable support, of means operated by the dragging movement of said shoe for adjusting said support.

10. In a car-brake, the combination with a rail brake-shoe, having an adjustable support, of a wheel-shoe adapted to be applied by the longitudinal movement of the rail-shoe, and means operated by said longitudinal movement for adjusting said support.

11. In a car-brake, the combination with a magnetic rail-shoe having an adjustable support, of means operated by the longitudinal movement of the rail-shoe for adjusting said support.

12. In a car-brake, the combination of a rail brake-shoe, an adjustable supporting-screw having projecting arms, and fixed stops for engaging said arms.

705,928. STOVE. WILLIAM HEUERMANN, Sedalia, Mo. Filed Mar. 4, 1902. Serial No. 96,586. (No model.)



Claim.—1. The improvement in stoves herein described, comprising the combustion-chamber or fire-box having an outlet-opening in its top, a top flue communicating with said opening and extending from end to end of the combustion-chamber, the offtake connected with said flue, the grate within the combustion-chamber, the draft-box below said grate and lateral to the combustion-chamber, the damper controlling said draft-box, the plate within the ash-box and overlying the opening between the draft-box and the ash-box, and the end sections having encircling flues provided with stop-plates and on one side of said stop-plates with nipples arranged to enter the opposite ends of the top flue and on the other side of said stop-plates with openings leading into the combustion-chamber, all substantially as and for the purposes set forth.

2. The combination in a stove with the combustion-chamber and the top flue extending along the same and provided with an opening communicating with the combustion-chamber and with a valve controlling said opening, of the sections at the ends of the combustion-chamber and provided with encircling flues each having a stop-plate and communicating on one side thereof with the end of the top flue and on the other side of said stop-plate with the interior of the combustion-chamber, substantially as and for the purpose set forth.

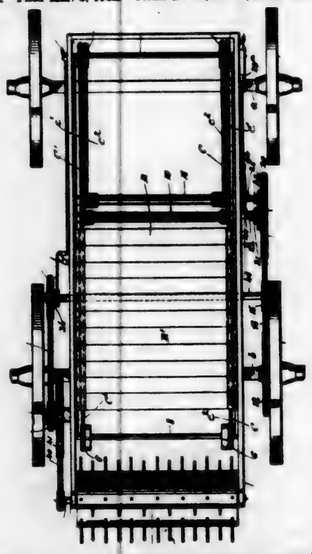
3. The combination in a stove with a combustion-chamber and a top flue, of the end sections hinged to the combustion-chamber and having encircling flues and nipples connecting the same with the opposite ends of the top flue, and having stop-plates and openings in the end flues, whereby the products of combustion from the combustion-chamber may be caused to circulate through the end flues and thence into the top flue and an offtake connected with the top flue, substantially as set forth.

4. The combination with the combustion-chamber, and a flue extending along the top thereof, and communicating at its middle with the combustion-chamber and having at its middle an offtake, of a valve controlling the communication between the top flue and the combustion-chamber, and the end sections having encircling flues arranged to receive the products of combustion from the combustion-chamber and to discharge such products to the opposite ends of the top flue, substantially as set forth.

5. The combination with the combustion-chamber, of flues encircling the opposite ends of the combustion-chamber and having openings through which to receive the products of combustion from the combustion-chamber, and an offtake in connection with said flues, substantially as set forth.

6. The combination of the combustion-chamber, the end sections having flues encircling the opposite ends of the combustion-chamber, a top flue in communication at its opposite ends with the opposite end flues, a door in one of the end sections, and a valve controlling direct communication between the top flue and the combustion-chamber, substantially as set forth.

705,929. MANURE-DISTRIBUTER. JOHN HOWELL, Schaller, Iowa. Filed Mar. 5, 1902. Serial No. 96,761. (No model.)



Claim.—1. A manure-distributer comprising a receptacle, suitable idler-pulleys near the front and rear portions of said receptacle, independent windlasses disposed between the idler-pulleys, cables fitted to said pulleys and having their opposite end portions coiled on the respective windlasses, a flexible bottom attached to and carried by said cables, a driving-shaft, and means for independently driving either of said windlasses from said shaft.

2. A manure-distributer comprising a suitable receptacle having supporting-pulleys near its front and rear portions, cables carrying a series of slats forming a flexible bottom, a driven shaft having a gear, separate windlasses disposed below the slatted bottom; the front portions of the cables passing in a forward direction from the bottom and coiled on one windlass, and the rear portions of said cables coiled on the other windlass and passing from the rear portion of the bottom, and thence around the front and rear pulleys, shiftable gears keyed on the windlasses, and means for individually adjusting said movable gears into and out of mesh with the driving-gear.

3. In a manure-distributer, the combination with suitable cables, and a flexible bottom having slats attached to said cables, of separate windlasses on which the opposite end portions of the cables are coiled, suitable brackets adjacent to said windlasses, shiftable gears keyed to the windlasses and provided with grooved hubs, adjusting-arms slidably fitted on said brackets and having depending shipper-forks loosely fitted in said hubs of the gears, rods connected to said arms and to a suitable operating-lever, and a shaft having a driving-gear with which the shiftable gears are adapted to independently mesh.

4. In a manure-distributer, a flexible bottom comprising suitable cables, transverse slats laid on said cables and provided with recesses in their upper faces, metallic plates fitted in said recesses, and U-shaped bolts embracing the cables and having their legs passed through the slats and plates and adapted to receive nuts which are countersunk in the recesses of the slats, substantially as specified.

5. A manure-distributer comprising a suitable receptacle, a windlass-driving shaft provided with a suitable gear, separate windlasses, each having a shiftable gear adapted to mesh with said gear of the shaft, cables having their end portions coiled on the respective windlasses and carrying suitable slats, a toothed distributing-cylinder disposed in rear of the flexible bottom, a cylinder-driving shaft extending across the receptacle and provided with a sprocket-gear, a driving-chain propelled by the movement of the distributer, and having operative connection with the cylinder-driving shaft and with the windlass-driving shaft, and a train of gearing between the cylinder-driving shaft and the cylinder, said gear-train including an intermediate shaft, and suitable means for throwing the train out of service.

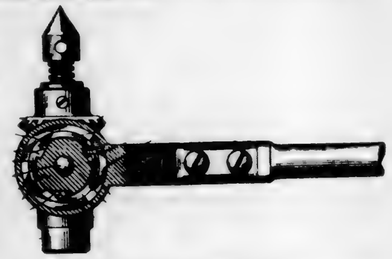
705,930. SAW-CLAMP. AUGUST J. JAEGER, Phillips, Wis. Filed Mar. 29, 1902. Serial No. 100,864. (No model.)

Claim.—1. A saw-clamp, comprising a substantially S-shaped member terminating at each of its ends in a screw-eye, and provided with a slide disposed adjacent to each of said eyes, a screw member engaging each of said eyes, and a flat plate mounted transversely upon each of said screw members, and provided with a bifurcated edge for straddling one of said slides, being guided thereby.

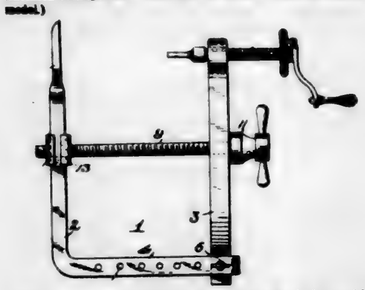
2. A saw-clamp, comprising a frame provided with a depending bracket, a screw-eye integrally mounted upon said bracket, a screw engaging said screw-eye, a plate mounted upon said last-mentioned screw, a jaw integrally mounted upon said frame opposite said last-mentioned plate, a jaw integrally mounted upon said frame at right angles with the jaw first mentioned, a bracket integrally mounted upon said frame and provided with a screw-eye and with a slide, a screw revolubly mounted in said screw-eye, and a plate provided with an aperture engaging said screw, and with a bifurcated end for straddling said slideway.

705,931. RATCHET MECHANISM. CHRISTIAN JOST, Berne Switzerland. Filed Apr. 18, 1900. Serial No. 13,159. (No model.)

Claim.—A ratchet mechanism comprising a part to be driven, having a hub, a ratchet inclosed by the hub, said ratchet having a plurality of peripheral, rectangular notches, the shorter walls of the notches being substantially radial to the axis of the ratchet, means for rotating said ratchet, a ring consisting of a plurality of segments located between the periphery of the ratchets and the inner surface of said hub, each segment terminating in a shoulder and the shoulders being situated in said rectangular notches, and the adjacent ends of certain of the segments having outwardly-diverging beveled faces and rollers fitted between the rings and the inner surface of the hub and adapted to cooperate with the said outwardly-diverging faces.



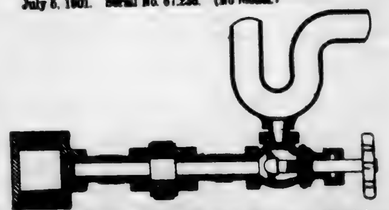
705,932. COMBINED VISE, DRILL, AND BOLT-HOLDER. ERASTUS L. KEARNEY, Highpoint, N. C., assignor of one-half to J. E. Northith, Davidson county, N. C. Filed Mar. 18, 1902. Serial No. 98,812. (No model.)



Claim.—1. In a device of the character described, the combination of stationary and movable arms each having a longitudinal slot, and a screw for adjusting the movable arm, said screw being adjustable in said slots, substantially as specified.

2. In a device of the character described, the combination of two arms, one of which is provided with a right angular support, means detachably connecting the other arm to said support, and means for adjusting the detachable arm toward and from the other arm, said means being longitudinally adjustable upon the arms, substantially as set forth.

705,933. TRAP-FLUSH. JOHN R. KETT, San Francisco, Cal., assignor of one-half to J. Raymond Smith, San Francisco, Cal. Filed July 5, 1901. Serial No. 67,236. (No model.)



Claim.—The combination of a drain-pipe having a U end therein to form a trap and having an aperture in the lowest part of said U end, a supply-pipe, a conduit leading from the supply-pipe to a point below said trap, a valve in said conduit, and a removable connection between the conduit and said aperture, said connection being open at both ends and having a conical inner surface, the smaller open end being connected with the conduit and the larger open end being connected with the aperture for the trap, substantially as described.

705,934. STETHOSCOPIC INSTRUMENT. ADOLPHUS A. KNUDSEN and FRANK H. CLARK, Brooklyn, N. Y. Filed Apr. 7, 1902. Serial No. 101,983. (No model.)

Claim.—1. In a device of the character described, the combination of a hollow case, a diaphragm therein, an air-chamber attached to and open-

ing into the hollow case, such chamber being provided with two apertures forming sockets, such sockets being disposed diametrically of the hollow case, tubes in the sockets and rotatable therein to fold in a plane parallel with the plane of the case or at an angle thereto, and means for retaining the ends of such tubes in the sockets, substantially as shown and described.

2. In a device of the character described, the combination of a hollow case, a diaphragm therein, two sockets opening into such case, such sockets being disposed diametrically of the hollow case, tubes in the sockets and rotatable therein to fold in a plane parallel with the plane of the case or at an angle thereto, and means for retaining the ends of such tubes in such sockets, substantially as shown and described.

3. In a device of the character described a hollow case, two metallic disks within such case, an annular band between the edges of such disks, an air-chamber attached to an opening into such hollow case, apertures therein forming sockets, such sockets being disposed diametrically of the hollow case, tubes in the sockets and rotatable therein to fold in a plane parallel with the plane of the case or at an angle thereto, substantially as shown and described.

4. In a device of the character described, a primary air-chamber, a diaphragm therein, a secondary air-chamber a diaphragm between such primary and secondary air-chambers and two tubes rotatably attached to such secondary air-chamber, to fold in a plane parallel with the plane of the case or at an angle thereto, substantially as shown and described.

705,985. MAGNETIC CORE FOR INDUCTANCE-COILS. JOHN C. LEE, Brookline, and EDWIN H. COLPITTS, Boston, Mass., assignors to American Telephone and Telegraph Company, a Corporation of New York. Filed Nov. 30, 1901. Serial No. 84,199. (No model.)

Claim.—1. The herein-described method of producing non-conducting magnetic cores for electromagnetic apparatus, which consists in subjecting divided magnetic metal assembled or laid up into a loosely-built or open-work mass of desired form to heat in an atmosphere capable of constantly yielding oxygen to the said metal, until the said mass is substantially converted to magnetic oxid.

2. An improvement in the art of producing cores of high electrical resistance and sufficient permeability, for inductance or loading coils, which consists in building plates wires or like thin elements of iron into proper form and size, and then submitting the same as a whole to the action of a high temperature in the presence of an oxygen-yielding atmosphere, until the iron is reduced or converted to ferroso-ferric oxid, substantially as set forth.

3. The hereinbefore-described method of making magnetic oxid cores for loading-coils, which consists in building or laying up iron plates, ribbon, or wire into a structure of desired form having interstitial spaces between the component layers or turns and extending to the exterior of the mass; in subjecting the said mass to strong heat in an oxidizing-chamber; and in supplying to said chamber an oxygen-containing medium such as steam which will readily give up oxygen to the iron, substantially as described.

4. The hereinbefore-described method of producing inductance or loading coil cores which consists in building, laying up or winding iron plates or wire into an open-work core structure of desired conformation; and in then converting the substance of said structure without change of form into a compact and relatively dense mass of artificial magnetic oxid of substantially uniform constitution, by heating or roasting the said structure in the presence of an oxygen-supplying medium such as steam or carbon dioxid, substantially as described.

5. A core for inductance-coils constituted of non-conducting material having high magnetic permeability, substantially as described.

6. A core for inductance or loading coils constituted of artificially-produced magnetic oxid.

7. A magnetic core for inductance or loading coils constituted of ferroso-ferric oxid formed in a compact mass by the substantially uniform oxidation of divided iron.

8. A magnetically-permeable core of high electrical resistance constituted of artificial magnetic oxid prepared in a solid and compact mass of desired conformation by oxidizing a structure built of plates, ribbons or wires of magnetizable metal into such conformation, substantially as described.

9. A magnetically-permeable and non-conducting core for inductance or loading coils composed throughout or mainly of ferroso-ferric oxid in a compact state, and of substantially uniform constitution, prepared by oxidizing a structure consisting initially of iron plates, strips or wire built up or wound into the desired form and size, substantially as set forth.

705,986. LOADED ELECTRIC CIRCUIT. JOHN C. LEE, Brookline, and EDWIN H. COLPITTS, Boston, Mass., assignors to American Telephone and Telegraph Company, a Corporation of New York. Filed Nov. 30, 1901. Serial No. 84,200. (No model.)

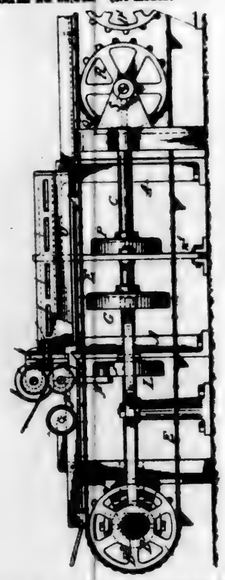
Claim.—1. A loading-coil, consisting of a core of continuous or compact high-resistance material having high permeability, and an electrical winding surrounding the said core, substantially as described.

2. A loading-coil having a properly-conformed compact mass of artificial magnetic oxid for a core, with an electrical winding surrounding the said core, substantially as described.

3. A loading or inductance coil comprising a magnetic core constituted of ferroso-ferric oxid formed in a compact mass, and an electrical conductor wound or coiled thereover, substantially as described.

4. An electrical circuit for the transmission of energy by varying currents provided with inductance-coils serially connected therein at proper intervals, the said coils having highly-permeable and high-resistance cores constituted of dense or closely-compacted magnetic oxid of iron or like magnetic metal or alloy, substantially as described.

705,987. MACHINE FOR APPLYING SOLDER TO METAL BLANKS. JOHN LEE, San Francisco, Cal., assignor to American Can Company, Jersey City, N. J., a Corporation of New Jersey. Filed Dec. 7, 1900. Serial No. 39,045. (No model.)



Claim.—1. In a machine for preparing blanks for the formation of soldered joints, the combination with means for holding or supporting a flat blank in a horizontal position, of parallel side guides for the ends of the blanks, and means for delivering one or more pieces of loose solder of proper length to form a seam, upon the surface of the blank, parallel and adjacent to but removed from the edges thereof, and means for causing said pieces to adhere in substantially the position in which they are delivered upon the blank.

2. In a machine for preparing blanks for the formation of soldered joints the combination with means for holding or supporting a flat blank in a horizontal position, and parallel side guides for the ends of the blanks, means for delivering a piece of loose solder of proper length to form a seam upon the surface of the blank parallel and adjacent to but removed from the edge thereof, and means for holding said piece and causing it to adhere in substantially the position in which it is delivered upon the blank.

3. In a machine for preparing blanks for the formation of soldered joints, the combination with a feed for a solder wire or strip, of a solder-cutter and means for supporting in a horizontal position a flat can-body blank beneath said cutter, and parallel side guides for the ends of the blank, whereby pieces of solder severed by said cutter fall upon said blanks.

4. In a machine for preparing blanks for the formation of soldered joints comprising means for propelling such blanks successively and flatwise in a horizontal position, parallel side guides for the ends of the blanks, means for feeding a solder-strip to a position above each blank, a solder-severing device, means for delivering the severed solder upon the surface of each blank, and means for heating and causing the solder-strip to adhere to each flat blank in substantially the position in which it is delivered upon the same, substantially as specified.

5. In a machine for preparing blanks for the formation of soldered joints, a guideway for said blanks, means intermittingly operated for propelling such blanks along it, an intermittingly-operated solder-feed, a solder-cutter, a support for the free end of the fed solder and means for removing said support so as to drop the severed piece upon the blank.

6. In a machine for preparing blanks for the formation of soldered joints, blank-propelling means intermittingly operated, a solder-strip feed intermittingly operated, a solder-cutter, a solder-support which receives solder from said feed, and maintains it above the blank, means for withdrawing said support and releasing the solder and a guide for delivering the severed solder in correct position upon the blank.

7. In a machine for preparing blanks for the formation of soldered joints, intermittingly-operated means for propelling a flat blank in a horizontal position, for feeding solder, for severing solder, and for delivering loose severed solder upon the surface of the blank, parallel and adjacent to but removed from the edges thereof, in combination with a heating device, and continuously-operating propelling means for conveying the blank carrying the loose solder in a horizontal position in proximity to the heating device, and parallel side guides for the ends of the blank.

8. In a machine for preparing blanks for the formation of soldered joints, the combination with the solder-wire feed, of a reciprocating cutter, a movable solder-holder, a solder-guide below the same, and mechanical connections for accomplishing operations of feeding the solder horizontally upon the holder severing a length of such solder, withdrawing the holder from beneath the solder, and so delivering a piece of solder through said guide.

9. In a machine for preparing blanks for the formation of soldered joints, the combination with a support upon which can-blanks lie and are propelled in a horizontal position, and side guides for the ends of the blanks, of an elongated solder-guide above the support having a contracted discharge in proximity to said support, and means for delivering lengths of solder-wire into said guide, which are thereby delivered in horizontal position upon the blanks adjacent to but removed from the edges thereof.

10. In combination with rolls arranged for feeding solder wire or strip horizontally, a cutter intermediate between said solder and rolls, and means for operating the cutter and releasing the piece of solder, thereby severed, from the holder, means for supporting and propelling flat blanks in a horizontal position, parallel side guides for the ends of the flat blanks, and a guide for the severed piece of solder, and means for heating the blanks and the solder-wire thereon and causing the solder to adhere to the blanks parallel and adjacent to but removed from the edges or seam-sections thereof, substantially as specified.

11. In a machine for preparing flat blanks for the formation of soldered joints, the combination with means for supporting and conveying the flat blanks in a horizontal position, of side guides for the ends of the blanks, means for delivering cut lengths of solder-wire adjacent to but removed from the edges of the blanks, and means for heating the blanks and the solder-stripe thereon and causing the same to adhere thereto adjacent to but removed from the edges of the blanks, substantially as specified.

12. The combination with means for supporting the flat blank in a horizontal position, with means for flattening and delivering the solder-wire in cut lengths upon the flat blank adjacent to but removed from the edges thereof, and means for causing the cut lengths of solder-wire to adhere to the blank in positions adjacent to but removed from the edges thereof, substantially as specified.

13. The combination with a horizontal table for supporting flat blanks, of parallel side guides for the opposite ends of the blanks, means for conveying the blanks along the table, a pair of solder-wire-feed devices, a pair of cutters for the solder-wire, a pair of guides for delivering the cut lengths of solder-wire upon the blanks in position adjacent to but removed from the edges of the blanks, and means for causing the cut lengths of solder-wire to adhere to the blanks in such positions, substantially as specified.

14. The combination with a horizontal table for supporting flat blanks, of guides for the edges of the blank, means for conveying the blanks along the table, a pair of solder-wire feeding and flattening devices, a pair of cutters for the solder-wire, a pair of guides for delivering the cut lengths of solder-wire upon the blank in positions adjacent to but removed from the edges of the blank, and means for causing the cut lengths of solder-wire to adhere to the blank in such positions, substantially as specified.

15. The combination with means for supporting and conveying flat blanks in a horizontal position, a pair of parallel side guides for the ends of the blanks, of a solder-wire-feed device, a solder-wire cutter, and a guide for the cut lengths of solder-wire for delivering the same on the flat horizontal blanks in a position adjacent to but removed from the edge thereof, and a heating device, substantially as specified.

705,988. PAINT. WILLIAM LEONARD FOOTE, Brooklyn, N. Y. Filed Oct. 28, 1901. Serial No. 80,217. (No specimens.)

Claim.—1. A composition of matter, consisting of talc, kaolin, silex, dissolved rubber, zinc oxid, diluted hydrofluoric acid, and silicate of soda.

2. A composition of matter, consisting of talc, kaolin, silex, corundum, dissolved rubber, zinc oxid, diluted hydrofluoric acid, and silicate of soda.

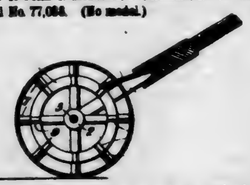
3. A composition of matter, consisting of talc, kaolin, silex, dissolved rubber, zinc oxid, an aqueous solution of alum, diluted hydrofluoric acid, and silicate of soda.

4. A composition of matter, consisting of talc, kaolin, silex, corundum, rubber in solution, zinc oxid, diluted hydrofluoric acid, alum in aqueous solution, silicate of potassium, and silicate of soda.

5. A composition of matter, consisting of one part talc, two parts kaolin, three parts silex, two parts corundum, three-fourths part rubber in solution, four parts zinc oxid, one and one-half parts diluted hydrofluoric acid, one-half part alum in aqueous solution, and sufficient silicate of soda to make the composition of a suitable paint-like consistency.

6. A composition of matter, consisting of one part talc, two parts kaolin, three parts silex, two parts corundum, three-fourths part rubber in solution, four parts zinc oxid, one and one-half parts diluted hydrofluoric acid, one-half part alum in aqueous solution, and sufficient of a mixture of equal parts of silicate of potassium and silicate of soda to make the composition of a suitable paint-like consistency.

705,989. SOUNDING TOY. LEE LOEB, Buffalo, N. Y., assignor of three-fourths to John C. McIntire, Jr., Buffalo, N. Y. Filed Sept. 30, 1901. Serial No. 77,084. (No model.)

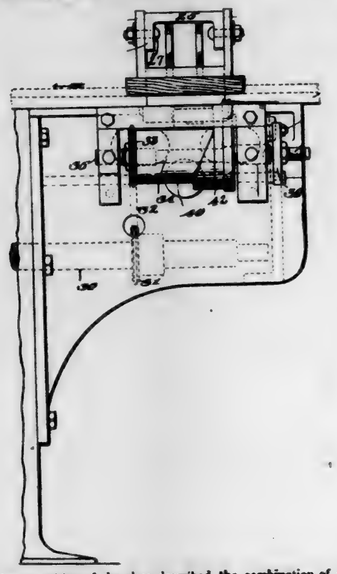


Claim.—In a sounding toy, a ground-wheel, a wheel encircled by the ground-wheel, and connected thereto, a handle, said handle having a V-shaped recess in its lower end, a clapper having one end pivoted in the V-shaped recess and adapted to bear against the walls of the recess for producing a spring action, the opposite end of the said clapper being bifurcated to embrace the wheels and engage the studs, as and for the purpose described.

705,940. FEED MECHANISM. HENRY HARLOW, Manor Park, England. Filed Feb. 24, 1902. Serial No. 96,282. (No model.)

Claim.—1. In a machine of the class described, the combination of a feed member, means for advancing the feed member toward the work and then moving the same in a direction to feed the work, and an automatically-operable lever adapted to impart a movement to the feed mem-

ber opposite the direction of feed and having a spring-arm for moving the feed member away from the work.



2. In a machine of the class described, the combination of a feed member, means for advancing the feed member toward the work and then moving the same in a direction to feed the work, and a spring-actuated lever for imparting a movement to the feed member opposite the direction of feed and having means for moving said feed member away from the work.

3. In a machine of the class described a feed member, means for advancing the feed members toward the work and then moving the same in a direction to feed the work, and a spring-controlled lever, the spring of which is adapted to move the feed member opposite the direction of feed and having a spring-arm adapted to move the feed member away from the work.

4. In a machine of the class described, a feed member having a slot, means for advancing the feed member toward the work and then moving the same in a direction to feed the work, and an automatically-operable lever having a spring-arm fitted in said slot the lever serving to move the feed member in a direction opposite that of the feed and its spring-arm, to move the feed member away from the work.

5. In a machine of the class described, a feed member, means for advancing the feed member toward the work and then moving the same in a direction to feed the work, an automatically-operable lever having a spring-arm, the lever being adapted to move the feed member in a direction opposite to that of the feed, and its spring-arm to move the feed member away from the work, and means for regulating the amount of movement of the feed member.

6. In a machine of the class described, a feed member, means for advancing the feed member toward the work and then moving the same in a direction to feed the work, an automatically-operable lever having a spring-arm, the lever being adapted to move the feed member in a direction opposite to that of the feed, and its spring-arm to move the feed member away from the work, and an adjustable stop disposed in the path of said lever.

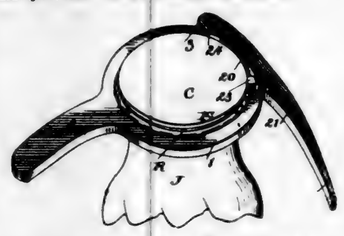
7. In a machine of the class described, a feed member, means for advancing the feed member toward the work, and then moving the same in a direction to feed the work, a lever having a spring-arm adapted to move the feed member away from the work, and a coiled spring connected with said lever and adapted through the latter, to operate the feed member in a direction opposite the line of feed.

8. In a machine of the class described, a feed member, a cam adapted to move the feed member toward the work, a second cam for moving the feed member in a direction to feed the work, and a spring-controlled lever having a spring-arm and adapted to return the feed member to the initial position thereof.

9. In a machine of the class described, the combination of a feed member and means for moving it toward and from the work and longitudinally forward and backward, a spring-arm having means to engage the work, and means for positively operating the spring-arm to cause it to engage the work as the backward movement of the feed member begins and for releasing said spring-arm as the forward movement of the feed member begins.

10. In a machine of the class described, a feed member, a cam for moving it toward the work, a second cam for moving the feed device longitudinally to advance the work, means for returning the feed device to its initial position, work-engaging means to prevent the rearward movement of the work during the return of the feed member, and a third cam for operating the work-engaging means.

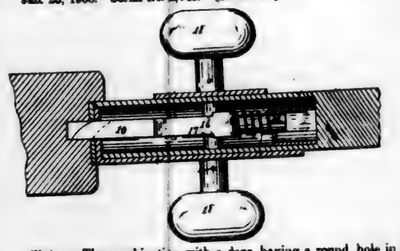
705,941. JAR-OPENER. WILLIAM S. MARSH, Intervale, Me. Filed Apr. 1, 1902. Serial No. 100,227. (No model.)



Claim.—1. The herein-described jar-opener made in two members, of which one comprises a ring and a handle, the other comprises a handle with a wedge projecting from that edge which stands toward the interior of the ring, and a pivotal connection between the two members.

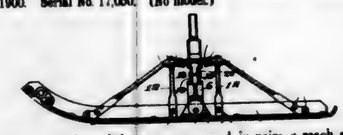
2. The herein-described jar-opener, the same consisting of one member having a ring-shaped body with a handle projecting from one side and an ear projecting from another side at a point about ninety degrees from the handle; a second member consisting of a nearly straight body dished at one edge to conform with the contour of the interior of said ring, having a handle at one end, and provided with a wedge projecting from said dished edge toward the interior of the ring; and a pin rising from said ear and engaging the other end of the last-mentioned member so as to permit the pivotal movement of the members on each other in parallel planes.

705,942. LOCK. WILLIAM A. MARKEY, Rosbyrock, W. Va. Filed Jan. 25, 1900. Serial No. 2,746. (No model.)



Claim.—The combination with a door having a round hole in the edge thereof, a spring-catch provided with a longitudinal slot therein, shoulders on said catch engaging lugs provided on a knob-shaft, and a shank on the rear end of said catch, of a cylindrical sleeve of equal diameter with the hole in the door slidably secured on the rear end of said shank and adapted to hold the catch rigidly in said hole, substantially as described.

705,943. SLED. CONRAD MILLER, Leadville, Colo. Filed May 17, 1900. Serial No. 17,050. (No model.)



Claim.—1. In a sled, runners arranged in pairs, a reach arranged between the same and connected to one pair of said runners, a forked coupling-head carried by said reach and provided with a shank, means

for detachably connecting said shank with the reach, and means for connecting the head with the other runners.

2. In a sled, runners arranged in pairs, a reach arranged between the same and connected to one pair of said runners, a forked coupling-head carried by said reach and provided with a shank, a clamping-collar for detachably connecting said shank with the reach, and means for connecting the head with the other runners.

3. In a sled, runners arranged in pairs, a reach arranged between the same and connected to one pair of said runners, a forked coupling-head carried by said reach and provided with a shank, a clamping-collar for detachably connecting said shank with the reach, and a pin for connecting the head with the other runners.

4. In a sled, runners arranged in pairs, a reach arranged between the same and connected to one pair of said runners, a turning-gear carried by the other pair, and a forked coupling-head connected to said reach, the fork of said head receiving and embracing said turning-gear.

5. In a sled, runners arranged in pairs, a reach arranged between the same and connected to one pair of said runners, said reach being provided with a downwardly-extending offset, and a coupling-head connected to said reach and also connected to the other pair of runners.

6. In a sled, runners arranged in pairs, a reach arranged between the same and connected to one pair of said runners, said reach being provided with a downwardly-extending offset, a turning-gear carried by the other pair of runners, and a forked coupling-head connected to said reach, the fork of said head receiving and embracing said turning-gear.

7. In a sled, runners arranged in pairs, a reach arranged between the same and connected to one pair of said runners, a turning-gear carried by the other pair and comprising a pair of plates working upon each other, one of said plates being provided with an extension having a segmental guide-slot, and the other plate carrying a guide-lug working in said slot, and a connection between said reach and said turning-gear.

8. In a sled, runners arranged in pairs, a reach arranged between the same and connected to one pair of said runners, a turning-gear carried by the other pair and comprising a pair of plates working upon each other, one of said plates being provided with an extension having a segmental guide-slot, and the other plate carrying a guide-lug working in said slot, and a swivel connection between said reach and said turning-gear.

9. In a sled, runners arranged in pairs, a reach arranged between the same and connected to one pair of said runners, a turning-gear carried by the other pair and comprising a pair of plates working upon each other, one of said plates being provided with an extension having a segmental guide-slot, and the other plate carrying a guide-lug working in said slot, and a coupling-head swiveled to said reach and connected to said turning-gear.

10. In a sled, runners arranged in pairs, a reach arranged between the same and connected to one pair of said runners, a turning-gear carried by the other pair and comprising a pair of plates working upon each other, one of said plates being provided with an extension having a segmental guide-slot, and the other plate carrying a guide-lug working in said slot, and a forked coupling-head swiveled to said reach and embracing the plates of said turning-gear.

11. In a sled, runners arranged in pairs, a reach arranged between the same and connected to one pair of said runners, a turning-gear carried by the other pair and comprising a pair of plates working upon each other, one of said plates being provided with an extension having a segmental guide-slot, and the other plate carrying a guide-lug working in said slot and provided with an aperture, a forked coupling-head swiveled to said reach and embracing the plates of said turning-gear, and a pin passing through said forked head and the aperture of the guide-lug.

12. In a sled, runners arranged in pairs, a reach arranged between the same, a roller carried by said reach and comprising a pair of superimposed plates, attaching-spindles removably secured to said plates and connected to one pair of said runners, and a connection between the reach and the other pair.

13. In a sled, runners arranged in pairs, a reach arranged between the same, a roller carried by said reach and comprising a pair of superimposed plates, attaching-spindles removably secured to said plates and connected to one pair of said runners, and a swivel connection between the reach and the other pair.

14. In a sled, runners arranged in pairs, a reach arranged between the same, a roller carried by said reach and comprising a pair of superimposed plates, attaching-spindles removably secured to said plates and connected to one pair of said runners, bearing-eyes carried by said runners and adapted to receive the attaching-spindles, and a connection between the reach and the other pair.

15. In a sled, runners arranged in pairs, a reach arranged between the same, a roller carried by said reach and comprising a pair of superimposed plates, attaching-spindles removably secured to said plates and connected to one pair of said runners, bearing-eyes carried by said runners and adapted to receive the attaching-spindles, braces carried by the reach and connected to said spindles, and a connection between the reach and the other pair of runners.

16. In a sled, runners arranged in pairs, a reach arranged between the same, a roller carried by said reach and connected to one pair of said runners, a pole carried by the other pair, and a roller carried by said pole for connecting it to said runners, said reach and pole rollers each comprising a pair of spaced plates, and attaching-spindles arranged therebetween for connection with the respective runners.

17. In a sled, runners arranged in pairs and each comprising a runner proper, a knee pivoted thereto, and a sectional supporting-beam connecting the knees of each runner, each of said beams being provided with an anchoring-iron arranged between its sections, and a reach arranged between the pairs of runners.

18. In a sled, runners arranged in pairs and each comprising a runner proper, a knee pivoted thereto, and a sectional supporting-beam connecting the knees of each pair, and a reach arranged between said pairs.

19. In a sled, runners arranged in pairs and each comprising a runner proper, a knee pivoted thereto, a brace secured to the runner proper and extending over said knee, and a sectional supporting-beam connecting the knees of each pair, and a reach arranged between said pairs.

20. In a sled, runners arranged in pairs and each comprising a runner proper, a knee pivoted thereto, a brace secured to the runner proper and extending over said knee, tie-rods connected to the runner proper and having an adjustable connection with the brace for supporting the latter, and a supporting-beam connecting the knees of each pair of runners, and a reach arranged between said pairs.

21. In a sled, runners arranged in pairs and each comprising a runner proper, a knee pivoted thereto, a brace secured to the runner proper and extending over said knee, tie-rods connected to the runner proper and the brace for supporting the latter, stops carried by said brace for limiting the movement of the runner on the knee, and a supporting-beam connecting the knees of each pair of runners, and a reach arranged between said pairs.

22. In a sled, runners arranged in pairs and each comprising a runner proper, a knee pivoted thereto, a brace secured to the runner proper and extending over said knee, tie-rods connected to the runner proper and the brace for supporting the latter, stops for limiting the movement of the runner on the knee, and a supporting-beam connecting the knees of each pair of runners, a reach arranged between the runners and connected to one of the pairs thereof, and a swivel connection between the reach and the other pair.

23. In a sled, runners arranged in pairs and each comprising a runner proper, a knee pivoted thereto and provided at its front and rear faces with recesses, and a sectional supporting-beam for connecting the runners of each pair, the members of said beam fitting within said recesses, and a reach arranged between the pairs of runners.

24. In a sled, runners arranged in pairs and each comprising a runner proper, a knee pivoted thereto and provided at its front and rear faces with recesses, means for limiting the movement of said runner proper on said knee, and a sectional supporting-beam for connecting the runners of each pair, the members of said beam fitting within the recesses of the knee, and a reach arranged between the pairs of runners.

25. In a sled, a runner comprising a runner proper, a U-shaped saddle embracing the runner proper, and a knee connected to said saddle.

26. In a sled, a runner comprising a runner proper, a U-shaped saddle embracing the runner proper, and a knee having its lower end bifurcated and receiving said saddle for connecting the knee to the runner proper.

27. In a sled, a runner comprising a runner proper, a saddle connected to said runner proper, the ends of said saddle converging to provide a comparatively long bearing-surface at the point of contact between the saddle and the runner proper, and a knee connected to said saddle.

28. In a sled, a runner comprising a runner proper of inverted-T shape in cross-section, a U-shaped saddle embracing the runner proper, and a knee having its lower end bifurcated and receiving said saddle for connecting the knee to the runner proper.

29. In a sled, a runner comprising a runner proper, a knee pivoted thereto, a brace secured to the runner proper and extending over the knee, and L-shaped stops carried by said brace for limiting the movement of the runner upon said knee.

30. In a sled, a runner comprising a runner proper, a knee pivoted thereto, a brace secured to the runner proper and extending over the knee, tie-rods also secured to the runner and the brace for supporting the latter, and stops carried by said brace for limiting the movement of the runner upon said knee.

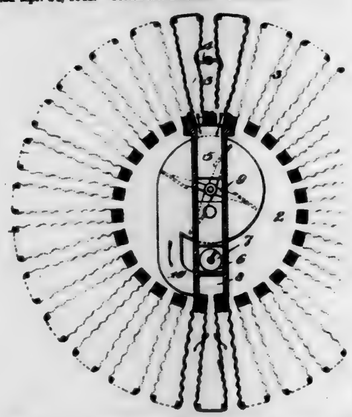
31. In a sled, a runner comprising a runner proper, a saddle embracing said runner proper, a knee having its lower end bifurcated and receiving said saddle to connect the knee to the runner proper, a brace secured to the runner proper and extending over the knee, and tie-rods also secured to the runner proper and the brace for supporting the latter.

32. In a sled, a runner comprising a runner proper, a saddle embracing said runner proper, a knee having its lower end bifurcated and receiving said saddle to connect the knee to the runner proper, a brace secured to the runner proper and extending over the knee, tie-rods also secured to the runner proper and the brace for supporting the latter, and stops carried by said brace for limiting the movement of the runner proper upon the knee.

33. In a sled, a runner comprising a runner proper of inverted-T shape in cross-section, a U-shaped saddle embracing said runner proper, a knee having its lower end bifurcated and receiving said saddle to connect the knee to the runner proper, a brace secured to the runner proper and extending over the knee, and tie-rods also secured to the runner proper and the brace for supporting the latter.

34. In a sled, a runner comprising a runner proper of inverted-T shape in cross-section, a U-shaped saddle embracing said runner proper, a knee having its lower end bifurcated and receiving said saddle to connect the knee to the runner proper, a brace secured to the runner proper and extending over the knee, tie-rods also secured to the runner proper and the brace for supporting the latter, and stops carried by the brace for limiting the movement of the runner proper upon the knee.

705,944. DUST-COLLECTOR. JOHN R. MITCHELL, St. Louis, Mo. Filed Apr. 24, 1902. Serial No. 104,552. (No model.)



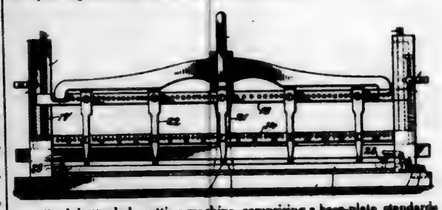
Claim.—1. In a dust-collector, a reel having a central drum into which dust-laden air is introduced and having filtering frames or pockets communicating with said drum, a main cut-off chamber in said drum, cleaning mechanism for the filtering frames or pockets which are for the time being in communication therewith, a supplemental cut-off chamber in said drum, and a reverse-draft fan having its inlet communicating with the main cut-off chamber and its outlet communicating with the supplemental cut-off chamber.

2. In a dust-collector, a rotatable reel having a central drum into which dust-laden air is introduced and filtering frames or pockets thereon, a plurality of cut-off chambers in said drum designed to communicate with one or more of said filtering frames or pockets and to cut off the dust-laden air in said drum from said pockets, cleaning mechanism coöperating with the filtering frames or pockets which are for the time being in communication with one of said cut-off chambers, and a back-draft fan having its inlet communicating with the cut-off chamber with which said cleaning mechanism coöperates and having its outlet communicating with the other of said cut-off chambers.

3. In a dust-collector, a reel having a central drum into which dust-laden air is introduced and having filtering mechanism communicating with said drum, a main cut-off chamber in said drum, cleaning mechanism for that part of the filtering mechanism which is for the time being in communication therewith, a supplemental cut-off chamber in said drum, and a reverse-draft fan having its inlet communicating with the main cut-off chamber and its outlet communicating with the supplemental cut-off chamber.

705,945. BUTTONHOLE-CUTTER. LEOPOLD F. MOSCK, New York, N. Y. Filed Dec. 21, 1901. Serial No. 86,753. (No model.)

Claim.—1. A buttonhole-cutting machine, comprising a series of cutting-blades, each blade having a plurality of cutting edges, standards, an upper cross-bar movable vertically with relation to the standards, a lower cross-bar movable vertically with relation to the standards, shank portions carrying the cutters and adjustably secured to said bars, and means for operating said bars, substantially as specified.



2. A buttonhole-cutting machine, comprising a base-plate, standards on said base-plate, upper and lower bars movable in said standards, cutter-carrying shanks adjustable along said bars, cutting-blades adjustable in the shanks, each blade having a plurality of cutting edges, a presser-bar engaging with one of said first-named bars, and an operating-lever connected to said presser-bar, substantially as specified.

3. A buttonhole-cutting machine comprising a base-plate, standards on said base-plate, cross-bars movable in said standards, cutters carried by said cross-bars, means for operating the cross-bars, and a gage-plate movable outward and inward with relation to the cutters, substantially as specified.

4. A buttonhole-cutting machine, comprising a base-plate, standards on said base-plate, cross-bars movable in said standards, springs for moving the cross-bars upward, a lever for moving the cross-bars downward, cutters carried by said bars and adjustable along the same, a gage-plate adjustable relatively to the cutters, and means for holding said gage-plate as adjusted, substantially as specified.

5. A buttonhole-cutting machine, comprising a base-plate, standards on said base-plate and provided with channels, one channel being forward of the other, a cross-bar movable in one of the channels, a cross-bar movable in the other of said channels, cutter-carrying shanks adjustably connected to said bars, cutters carried by said shanks, means for operating the bars, and a holding-clamp for the goods to be operated upon, substantially as specified.

6. A buttonhole-cutting machine, comprising a base-plate, standards on the base-plate, bars movable in the standards, cutter-carrying shanks attached to the bars, cutters carried by the shanks, and covering-hoods for the cutters, substantially as specified.

7. In a buttonhole-cutting machine, a cutter-carrying shank, and a cutter adjustable in said shank, the said cutter having a plurality of cutting edges of different lengths, substantially as specified.

8. In a buttonhole-cutting machine, a cutter-carrying shank, and a cutter adjustable in said shank, the said cutter having a plurality of cutting edges of different lengths, and an eyelet-cutter at one end of each cutting edge, substantially as specified.

9. In a buttonhole-cutting machine, a cutter-carrying shank having fingers at its lower end, a cutter-plate arranged between said fingers, means for clamping said plate, and a plurality of cutting edges on said plate, the said cutting edges being of different lengths, substantially as specified.

10. In a buttonhole-cutting machine, a cutter-carrying shank having fingers at its lower end, a cutter consisting of a plate having a plurality of cutting edges of different lengths, the said plate being recessed at its opposite sides to receive said fingers, and means for clamping the plate between the fingers, substantially as specified.

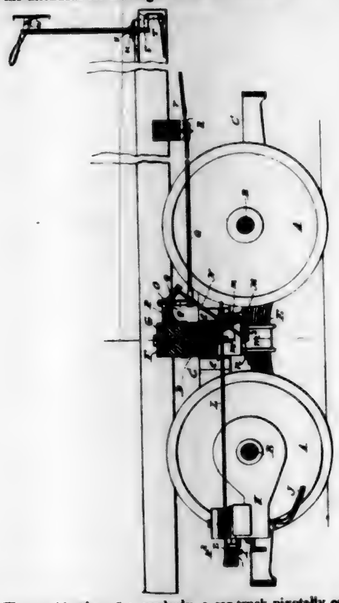
705,946. CAR-BRAKE. JOHN R. MONTAGUE, Syracuse, N. Y., assignor to Hydraulic Car-Brake Company, Syracuse, N. Y., a Corporation of New York. Filed Oct. 16, 1901. Serial No. 78,807. (No model.)

Claim.—1. The combination of a car-body, a car-truck pivotally connected therewith; brake-applying mechanism supported by the car-truck and brake-controlling mechanism flexibly connected with the brake-applying mechanism below and in line with the axis about which the truck moves relatively to the car-body.

2. The combination of a car-body; a car-truck pivotally connected therewith, brake applying mechanism, a rocking lever connected with said brake mechanism, another rocking lever, means for operating it, and connections between the two rocking levers having a pivot in line with the axis about which the truck moves relatively to the car-body.

3. The combination of a car-body, a car-truck pivotally connected therewith, fluid-pressure brake mechanism, a valve-operating rod connected therewith, a rocking lever connected with said valve-rod, another rocking lever, means for operating it and connections between the two rocking levers having a pivot in line with and below the axis about which the car turns.

4. The combination of a car-body, a truck pivotally connected therewith, two rock-shafts, a rod connecting said rock-shafts and having a jointed connection with one of them in line with the axis about which the truck turns relatively to the car-body, means for connecting the brake-operating mechanism with one of said rock-shafts and devices under the control of the attendant for moving the other rock-shaft.



5. The combination of a car-body, a car-truck pivotally connected therewith, two rock-shafts, a rod connecting the rock-shafts and having a jointed connection with one of them in line with the axis about which the truck turns, valve mechanism, means connecting one of the rock-shafts with said valve mechanism, brake-controlling mechanism, and means connecting said mechanism with the other of said rock-shafts.

6. The combination of a car-body, a car-truck pivotally connected therewith, the upper rock-shaft having laterally-projecting arms, the lower rock-shaft also having laterally-projecting arms, a rod connected to arms on the two rock-shafts and having a jointed connection with the lower rock-shaft in line with the axis about which the truck turns relatively to the car-body, connections leading from the other arm on the lower rock-shaft to the brake-applying mechanism and connections leading from the other arm on the upper rock-shaft to the brake-controlling mechanism.

705,947. AIR COOLING, DRYING, AND PURIFYING APPARATUS. WILLIS L. MOORE, Washington, D. C. Filed May 29, 1902. Serial No. 109,497. (No model.)

Claim.—1. In an air-cooling apparatus, the combination of an ice-compartment, reticulated tubes extending through the same for diffusing air through the ice; an intermediate bottom for sustaining the ice in the upper compartment, a drip-pan for catching the flow of water from the intermediate bottom; a discharge-pipe for conducting the drip-water from the upper compartment to the bottom of the lower compartment; a second ice-compartment immediately below the first for the reception of ice and some chemical that lowers the melting point of ice, tubes arranged in the lower compartment for the passage of air through the same, a suction-fan to energize the operation of the machine, a damper to regulate the flow of air into the top of the shell, and a trough encircling the shell to catch the moisture that may condense on the outside of the shell.

2. A two-compartment air-cooling apparatus having ice-containing devices for the upper compartment with vertical reticulated or perforated tubes through the same, open at their upper ends, vertical pipes in the lower compartment opening at their upper ends below the ice-chamber, and means for maintaining the level of the meltage-water in the lower compartment below the level of the upper ends of the vertical air-pipes substantially as described.

3. An air-cooling apparatus comprising a casing, an intermediate bottom with openings through its edges next the casing, reticulated or perforated tubes arranged in the upper compartment, a drip-pan arranged below the intermediate bottom and having a drain-pipe leading into the lower compartment, air-tubes arranged in the lower compartment and opening below and protected by the drip-pan, and opening at their lower ends through the lower compartment, an overflow tapped into the lower compartment below the level of the upper ends of said air-tubes, and a drain-pipe tapped into the lower part of the lower compartment and also into the overflow-pipe and having a cut-off valve, and an external trough for the bottom of the casing also tapped into the overflow-pipe substantially as shown and described.

4. A two-compartment air-cooling apparatus having ice-containing devices for the upper compartment, a drip-pan arranged beneath the same and having central discharge-pipe leading to the lower compartment, vertical pipes in the lower compartment arranged about the drip-discharge pipe and opening at their upper ends below the drip-pan, and means for maintaining the level of the meltage-water in the lower compartment below the level of the upper ends of the vertical air-pipes in the lower compartment substantially as described.

5. An air-cooling apparatus having an ice-chamber with an intermediate bottom or diaphragm having openings through it around its outer edges and a central drainage-hole, a subjacent drip-pan, and vertical tubes of reticulated or perforated material open at their upper ends and arranged in said intermediate bottom and opening through the same and above said drip-pan substantially as described.

6. An air-cooling apparatus made in two compartments, the upper compartment having an intermediate bottom or supporting-diaphragm for ice with openings through it, and a subjacent drip-pan with central discharge-pipe, vertical tubes in the lower compartment surrounding the central drip-discharge pipe and opening at their upper ends into the lower compartment below the drip-pan and covered by the same to exclude drip-water from the tubes substantially as described.

7. An air-cooling apparatus made in two compartments, the upper compartment having an intermediate bottom or supporting-diaphragm for ice with openings through it, a subjacent drip-pan with central discharge-pipe, a series of vertical pipes in the lower compartment surrounding the drip-discharge pipe and opening at their upper ends below the drip-pan and covered by the same to exclude drip-water, and an overflow-pipe tapped into the lower compartment at a point below the upper ends of said pipes substantially as described.

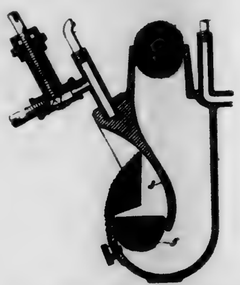
8. An air-cooling apparatus having two compartments, one above the other, the upper one having means for holding the ice in it and open-meshed or perforated tubes through it opening at their upper ends into the top of the upper compartment and at their bottoms into the top of the lower compartment, the lower compartment being made as a trapped chamber and having vertical air-pipes through it opening at their upper ends below the upper compartment and adapted to receive a freezing mixture to produce a lower temperature than in the upper compartment substantially as described.

9. A two-compartment air-cooling apparatus consisting of an upright cylinder having ice-containing devices for the upper compartment, vertical pipes in the lower compartment opening at their upper ends below the ice-containing devices with a free space between said upper ends of the pipes and the ice-containing devices above, and doors arranged in the sides of the cylinder at an intermediate point of the cylinder opposite said free space to permit the introduction of a freezing mixture in the lower compartment substantially as shown and described.

100 O G.—67

10. A two-compartment air-cooling apparatus having ice-sustaining devices for the upper compartment, and an air-space below said ice-sustaining devices, a series of vertical pipes arranged in the lower compartment and opening at their upper ends into the lower portion of the air-space below the ice-sustaining devices, means for trapping the meltage-water around the vertical pipes of the lower compartment without overflowing into said pipes and an air-discharge conduit communicating with the bottom ends of said vertical air-pipes substantially as described.

705,948. HYDROCARBON-BURNER. MARSHAL W. MORGAN, Mount Vernon, Ind. Filed Aug. 1, 1901. Serial No. 70,496. (No model.)



Claim.—1. In a hydrocarbon-burner, a body having a fixed chamber, a side wall of the body being curved downward and inward forming one wall of an inlet, a perforated burner at the outlet end, spaced screens at the inlet end of said chamber, a tube attached at its ends to the burner-body, a valve-casing having communication with said tube, a valve controlling the outlet of said casing, there being an open-air space between said outlet and the screens, and a supply-tube communicating with the first-named tube, substantially as specified.

2. In a hydrocarbon-burner, a body having a fixed chamber, a side wall of the body being curved downward and inward, forming one wall of an inlet, a perforated burner at the outlet end, spaced screens at the inlet end of said chamber, a tube attached at its ends to the burner-body and extended vertically and having a portion extended transversely for supporting a mantle, a valve-casing having communication with said tube, a valve controlling the outlet of said casing, there being an open-air space between said outlet and the screens, and a supply-tube communicating with the first-named tube, substantially as specified.

705,949. CARTRIDGE. GUSTAV MÜLLER, Duesseldorf, Germany, assignor to Firm Rheinische Metallwaaren- und Maschinenfabrik, Duesseldorf-Derendorf, Prussia, Germany. Filed Feb. 25, 1901. Serial No. 48,708. (No model.)

Claim.—1. A metallic cap for a cartridge provided with a yieldable spring end portion for the projectile to bear against, substantially as set forth.

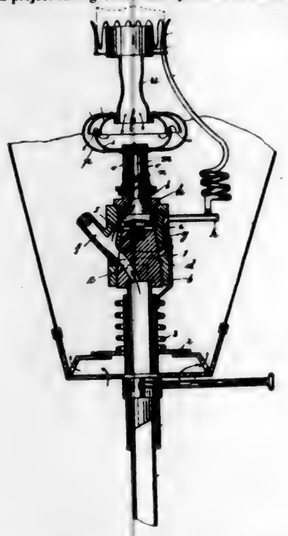
2. The combination, with a cartridge-shell, of a metallic cap closing the front end of the shell and provided with a yieldable spring end portion, substantially as set forth.

3. A cap for a cartridge provided with spring-tongues struck up from the metal of its end portion, substantially as set forth.

705,950. INCANDESCENT GAS-BURNER. ALEXANDRE MURINE, St. Petersburg, Russia. Filed Nov. 21, 1900. Serial No. 37,315. (No model.)

Claim.—1. In an incandescent burner the combination with the feed-opening for the gas-supply and the burner, of a chamber for mixing the gas with air, said chamber being constructed with concentrically-arranged upper cup-like shells secured at their upper narrow edges to a ring for receiving the burner and having spaces between their wider lower edges, lower shells of similar shape which are connected with their lower narrow edges to a ring closely surrounding the gas-inlet and project with their upper wider edges into the spaces left between the lower edges of the upper shells, and outwardly-bent springs connected at their ends with said rings, substantially as and for the purpose stated.

2. In an incandescent burner the combination with the cone fixed to the gas-supply pipe, the housing rotatably mounted upon said cone, and the gas-channels formed in the cone and housing, of a gas-chamber formed by the upper part of the housing, a conically-hollowed plug screwed into the top part of the housing and having a centrally-bored axially-arranged extension on top, a hollow cylinder screwed on said extension and having a perforated bottom and open top, a needle axially fixed within the hollow of the cylinder, and another hollow cylinder adjustably mounted upon the first-named cylinder and having a conical opening in its top for said needle to project through, substantially as and for the purpose stated.



705,951. FENCE-LOCK. WILLIAM R. MACLEAN, Galetta, Canada. Filed Oct. 13, 1900. Serial No. 32,941. (No model.)

Claim.—1. A lock for locking a wire to a post or picket, comprising a U-shaped clip adapted to receive a wire between its parallel members and having vertically-alined bearings in said members to receive a post or picket, and integral locking-arms projecting from the ends of the portion connecting the parallel members, said arms being adapted to be bent so as to engage with their inner edges the wire and force it in firm contact with the post or picket, as set forth.

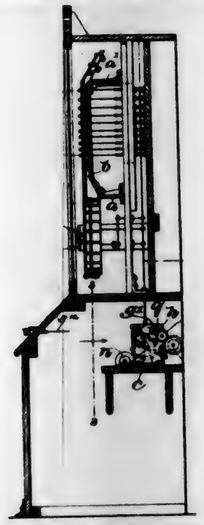
2. A lock for locking a wire to a post or picket, consisting of a U-shaped clip adapted to receive a wire between its parallel members and having vertically-alined openings in said members to receive a post or picket, and integral locking-arms projecting from the ends of the portion connecting the parallel members, said arms having their inner edges recessed or notched and adapted to be bent into engagement with the wire to force it into firm contact with the post or picket, as set forth.

705,952. MECHANICAL MUSICAL INSTRUMENT. JOHN MCTAMMANY, Spencer, Mass. Filed July 9, 1898. Serial No. 685,481. (No model.)

Claim.—1. In combination with the string of a musical instrument, an actuator, a string-controller, a coupler provided with a relatively movable dog resting in potential relation to the actuator, and an automatic selecting apparatus for projecting the dog into operative engagement with its actuator at the desired intervals.

2. The combination in a stringed musical instrument of a series of string-controllers, an actuator common to all the controllers, a series of couplers, each provided with a relatively movable dog arranged and resting in potential relation to the actuator, and an automatic selecting apparatus for projecting the dogs into operative engagement with the actuator.

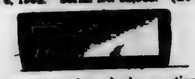
3. The combination of a stringed musical instrument, a series of string-controllers, an actuator common to all the controllers, a series of couplers between the actuator and the controllers, each coupler including a slide in juxtaposition to the actuator, and a dog movable in the slide toward and from the actuator, and an automatic selecting apparatus adapted to operatively project the said dogs in a predetermined order.



4. The combination of a stringed musical instrument, a series of string-controllers, an actuator common to all the controllers, a series of couplers between the actuator and the controllers, each coupler including a slide in juxtaposition to the actuator, and a dog movable in the slide toward and from the actuator, a series of levers adapted to project said dogs, and a progressively-moving program device adapted to release and control said levers in a predetermined order.

5. The combination of a stringed musical instrument, a series of string-controllers, an actuator common to all the controllers, a series of couplers between the actuator and the controllers, each coupler including a slide in juxtaposition to the actuator, and a dog movable in the slide toward and from the actuator, a series of levers adapted to project said dogs, each having a shoulder arranged to engage the dog of the accompanying slide when the dog-projecting movement of the lever is prolonged, and a perforated sheet against which said levers bear yieldingly.

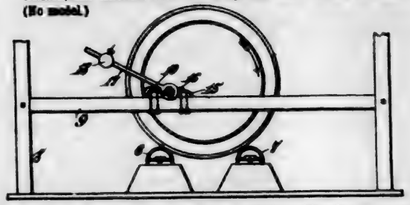
705,953. KNOCKDOWN BOX. JACOB B. NEHEISEL, New Orleans, La. Filed Feb. 6, 1902. Serial No. 92,903. (No model.)



Claim.—1. A knockdown box, the box portion having an end flap bent upon itself and turned down inside said portion, slits formed in the bottom of the box radiating from the corners of the base of the said flap toward the center of the box-bottom, side flaps, a portion of each of which is folded upon itself and folded down into the box portion, the remaining portion of the side flaps lying flat upon the bottom of the box portion with their contiguous edges snugly abutting, whereby the folds in the side flaps are firmly braced against each other, the unfolded portions of the side flaps forming a supplemental bottom in the box portion, and an end wall bent up from the bottom, a cover integral with the same and bent over the box, and an endless flexible band secured in the said slits in the bottom of the box adapted to be secured around and secure the box in a closed position.

2. A knockdown box, the box portion having an end flap bent upon itself and turned down inside said portion, slits formed in the bottom of the box radiating from the corners of the base of said flaps toward the center of the box-bottom, side flaps, a portion of each of which is folded upon itself and folded down into the box portion, the remaining portion of the side flaps lying folded upon the bottom of the box portion with their contiguous edges snugly abutting whereby the folds of the side flaps are firmly braced against each other, the unfolded portions of the side flaps forming a supplemental bottom in the box portion, an end wall bent up from the bottom, a cover integral with the same and bent over the box, tongues formed integral with and extending sidewise from the base of the end flaps or folds, and adapted to lock between the folded portions of the side flaps, and an endless flexible band secured in the side walls in the bottom of the box and adapted to pass around and secure the box in a closed position.

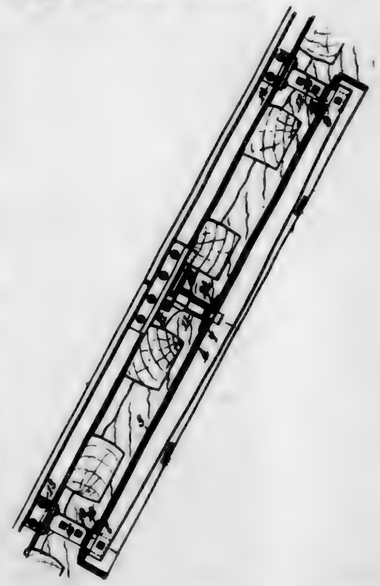
705,954. SCRAPER FOR ASPHALT-COOKING DRUMS. JOHN P. NELSON, San Antonio, Tex. Filed Apr. 21, 1902. Serial No. 104,005. (No model.)



Claim.—1. The combination of an asphalt-cooking drum, a scraper-plate having a straight edge adapted to bear against the inner surface of said drum, a shaft carrying said scraper-plate and extending beyond the drum, a weighted arm carried by the shaft outside the drum, and adjustable bearings for said shaft.

2. The combination of an asphalt-cooking drum, a scraper-plate having a straight edge adapted to bear against the inner surface of said drum, a shaft carrying said scraper-plate and extending through and beyond the drum, weighted arms carried by the shaft outside the drum, and the weights thereof being adjustable and horizontally-adjustable bearings for said shaft.

705,955. RAIL-SUPPORT. CARL E. NEUBAUER, Virginia, Minn., assignor of one-half to Alfred Burke, Ida Krause, and Joseph Karl, Virginia, Minn., and Frank Julius Dahlberg, Buhl, Minn. Filed Feb. 10, 1902. Serial No. 93,406. (No model.)



Claim.—1. In a rail-support, a beam, said beam having rail-supports at its ends, and an intermediate adjustable joint-support.

2. In a rail-support, a beam having rail-supports and a screw intermediate said rail-supports, and a nut on said screw, said nut and screw constituting a joint-support.

3. In a rail-support, a beam, said beam having rail-supports at its ends, and an intermediate adjustable joint-support, combined with a car-

ing for inclosing the beam, said casing having openings through which said supports project.

4. In a rail-support, a beam having rail-supports and an intermediate adjustable joint-support, a casing for inclosing said beam, said casing being of greater width than the beam, and having openings through which said supports project.

5. In a rail-support, a beam having rail-supports and a screw between said rail-supports, and a nut on said screw, the nut being provided with ratchet-teeth and the nut and screw constituting a joint-support, and a pawl mounted to engage said ratchet-teeth.

6. In a rail-support, a beam having rail-supports and an intermediate adjustable joint-support, a casing for inclosing said beam, said casing being perforated, and the said supports extending through said perforations, and plates surrounding said supports and closing said perforations.

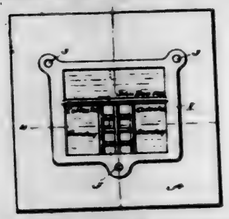
7. In a rail-support, a beam having rail-supports and an intermediate adjustable joint-support, and clamps adapted to be fastened to the rails and having depending plates rigidly connected with said rail-supports.

705,956. COMPOSITION FOR CLEANING AND PRESERVING METALS. WILLIAM C. OBERWALDER, New York, N. Y. Filed Feb. 7, 1902. Serial No. 92,972. (No specimens.)

Claim.—1. The composition of matter for cleaning and preserving the polish of metals, said composition consisting in an abrasive material, sulfate of soda, borax, pulverized camphor, and a soapy substance combined in essentially the proportions stated.

2. A composition of matter for cleaning and preserving and polishing metals, said composition consisting in an abrasive material, sulfate of soda, borax, pulverized camphor, carbonate of magnesium, and a soapy substance combined in essentially the proportions stated.

705,957. STREET LETTER-BOX. FRANK D. OSBORN, Birmingham, Ala., assignor of one-half to Alexander C. Macpherson, Brooklyn, N. Y. Filed Feb. 5, 1902. Serial No. 92,662. (No model.)



Claim.—1. In a letter-box of the class described, the combination with a box-wall having a sunken panel with the upper connecting offset portion cut through to form a narrow slot for the insertion of a card, a transparent plate fitting the panel-recess in front of the slot, and a metal frame covering the joint between the plate and the surrounding wall, and devices, releasable only on the inner side of said wall, detachably securing said frame to said wall.

2. In a letter-box of the class described, the combination with the box-wall having an integral sunken panel of which a portion is removed leaving an opening through the wall and further having a narrow card-admitting slot through the upper offset portion connecting the panel and non-sunken wall, a transparent plate fitting the panel-recess in front of the plane of said slot, a frame covering the joint between the plate and the wall surrounding it and provided with an integral grating in front of said opening, and devices, releasable only from the inner side of the wall, detachably fixing the frame to the wall.

3. In a letter-box of the class described, the combination with the box-wall having the partially-cut-away sunken panel provided with the outwardly-extending rib around the opening formed by such cutting away and further having along one side of the panel a slot extending through the offset formed by sinking the panel, of a glass plate overlying the panel and resting against said rib, and the frame having the integral grating covering said opening and secured to the wall to cover the margins of the glass and hold it against said rib, substantially as set forth.

4. In a letter-box of the class described, the combination with the box-wall having an integral sunken panel provided with an opening through its lower central portion and with an outwardly-extending rib around said opening, and further having a narrow slot through the upper offset formed in sinking the panel, a transparent plate fitting the panel-recess and held in front of the plane of said slot by said rib, a metal frame covering the joint between said plate and the surrounding wall and provided with a grating and integrally connected at top and bottom with said frame, and devices releasable only from the inner side of the wall, detachably fixing said frame to said wall.

5. In a letter-box, the combination with a box-wall pressed inward to form a sunken panel and having the upper offset slotted from end to end to admit sliding a card downward along the outer face of the panel, said panel being cut away centrally at its upper side to allow the finger to raise the card and cut away centrally below, to form a sight-opening, and provided with an outwardly-extending flange around the margin of the opening, a transparent plate fitting the panel-recess and resting against said flange, and a metal frame covering the joint between the plate and the surrounding wall and provided with a grating registering with said opening and integrally connected at top and bottom with said frame.

705,958. FOUNTAIN-PEN. RIDLEY C. PAINE, Bethel, N. Y. Filed Nov. 21, 1901. Serial No. 83,144. (No model.)

Claim.—1. A fountain-pen, comprising a casing having in its end carrying the pen a contracted opening, the outer wall of which flares outwardly to form a conical valve-seat, a rocking feeder adapted to move in and out through the valve-seat by gravity to feed the ink to the pen and to drain the ink therefrom, and a cap adapted to be secured on the casing and provided with a valve for engaging the said valve-seat when the cap is in position, as set forth.

2. A fountain-pen, comprising a casing having in its end carrying the pen a contracted opening, the outer wall of which flares outwardly to form a conical valve-seat, a weighted feeder mounted to slide and rock, whereby the feeder will be first moved out through the valve-seat and then swung into contact with the pen-point automatically, and a cap adapted to be secured on the casing and provided with a valve adapted to engage the said valve-seat when the cap is in position, as set forth.

3. A fountain-pen, comprising a casing provided with a conical valve-seat at its end forming a contracted opening leading into the casing, said end being adapted to carry a pen-point, a weighted feeder mounted to slide and rock in the casing and having an offset near its outer end, the portion beyond the offset being parallel with the body of the feeder and adapted to engage the pen-point when projected out through the valve-seat, and a cap adapted to be secured on the casing and provided with a valve for engaging the valve-seat when the cap is in position, as set forth.

4. A fountain-pen, comprising a casing provided with a nozzle having at its end a conical valve-seat forming a contracted opening leading into the casing, said end being adapted to carry a pen-point, a feeder mounted to swing and slide on a transverse pivot and provided with a weight at its inner end, said feeder having an offset near its outer end, the portion beyond the offset being parallel with the body of the feeder and engaging the pen-point when projected, means for limiting the sliding movement of the feeder, and a cap adapted to be secured on the nozzle and provided with a valve for engaging the said valve-seat when the cap is in position, as set forth.

5. A fountain-pen, comprising a casing provided with a nozzle having a conical valve-seat at one end and adapted to carry a pen-point at said end, a feeder slotted intermediate of its ends and provided with a weight at its inner end and having an offset outer end for engaging a pen-point a transverse pin forming a fulcrum for the feeder, a pin extending into the slot of the feeder, and a cap screwing on the nozzle and provided with a valve engaging the valve-seat, as set forth.

6. In a fountain-pen, the combination of a casing adapted to carry a pen at one end and having a contracted opening in said end, the outer wall of which opening flares outwardly, and a weighted feeder mounted to rock and slide in the casing, said feeder being provided with an offset near its outer end, for engaging the wall of the said opening, the portion beyond the offset being parallel with the body of the feeder and adapted when projected to engage the pen-point, as set forth.

7. In a fountain-pen, the combination with a casing adapted to carry a pen-point at one end and having an opening in said end, the outer wall of which opening flares outwardly, and a feeder slotted intermediately of its ends and provided with a weight at its inner end and with an offset near its outer end, the offset being adapted to engage the wall of the opening and the portion beyond the offset to engage the pen-point, a transverse pin in the casing upon which the feeder is fulcrumed, and a second pin projecting into the slot of the feeder, as set forth.

8. A fountain-pen, comprising a casing provided with a nozzle having a contracted opening at its end, the outer wall of the opening being flared outwardly, a pen-point carried by the nozzle and provided with a tongue having its rear end longitudinally split, and a weighted and rocking feeder adapted to move in and out through the contracted opening by gravity to engage the tongue of the pen to feed the ink thereto and to drain the ink therefrom.

9. A fountain-pen, comprising a casing provided with a nozzle having in its end a contracted opening, the outer wall of which is flared outwardly, a pen-point carried by the nozzle and provided with a tongue having its rear end slit longitudinally, and a weighted feeder mounted to slide and swing on a transverse pivot arranged between its ends, the end of the feeder when projected engaging the tongue of the pen-point, as set forth.

705,959. FLY-TRAP. ESSEX POTTER, Greensburg, Ind. Filed Nov. 20, 1901. Serial No. 83,053. (No model.)

Claim.—1. The combination with a screen formed with an opening, of a grooved collar having an annular flange and fitting in said opening, a cone having an opening in its apex, and a flange secured to said cone adapted to fit in said annular flange to secure the cone to the screen.

2. The combination with a screen formed with an opening, of a grooved collar having an annular flange and fitting in the opening, said flange being provided with bayonet-slots, a cone having an opening in its apex, a flange secured to said cone adapted to fit in said annular flange to secure the cone to the screen, a trap, a flange secured to said trap, and lugs upon the last-mentioned flange adapted to engage said bayonet-slots.

3. The combination with a trap, of a grooved flange secured to the base of said trap, a disk having an opening and fitting in said groove to close the bottom of said trap, and a cone fitting in said opening.

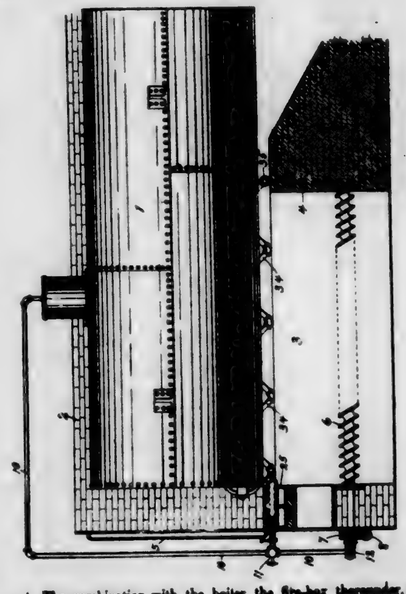
4. The combination with a screen formed with an opening, of a grooved collar having an annular flange and fitting in said opening, a cone having an opening in its apex, a flange secured to said cone adapted to fit in said annular flange, securing the cone to the collar, a semispherical trap, a grooved flange secured to said trap, a disk having an opening and fitting in said groove, a grooved collar having a flange and fitting in said last-mentioned opening, a lug upon said flange to engage a bayonet-join in said first-mentioned flange.

705,960. BOILER-FURNACE. ALEXANDER M. RANKIN, New York, N. Y., assignor to Oscar B. Madden, New York, N. Y. Filed Sept. 20, 1901. Serial No. 75,788. (No model.)

Claim.—1. A furnace having a gas-head at the center of the front of the fire-box above the level of the grates, said head having jet-apertures opening to the fire-box, means for supplying highly superheated or gasified steam to said gas-head, water-receptacles situated, respectively, above and below the jet-apertures therein, and means for supplying said receptacles with water, substantially as set forth.

2. A furnace having a steam-pipe, or series of connected steam-pipes, extending about the fire-box along the sides and bridge-wall of same, and a gas-head at the front of the fire-box above the fuel-bed and connected to the end of said series of pipes, said gas-head having in its side next the fire-bed a series of jet-apertures for the escape of the gasified steam, and a protecting water-conduit above said apertures.

3. A furnace having a water-base 26, mounted in its front wall, in combination with a boiler, pipes connecting said water-base with the boiler, a steam-pipe extending about the fire-box and connected at one end with the boiler and at the other end with a gas-head, 26, on the water-base, the said gas-head provided with jet-apertures 28 for the escape of the gasified steam to the fire-box, and provided with a protecting water-conduit 30, and the pipes connecting said conduit with the water-space of the boiler.

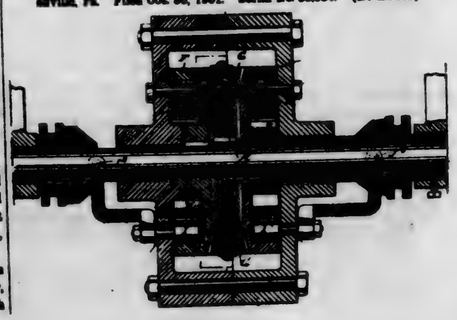


4. The combination with the boiler, the fire-box thereunder, and the grate-bars forming the fire-bed, of the water-base in the front wall of the fire-box, pipes connecting said water-base with the water-space in the boiler, a gas-head mounted on said water-base and having jet-apertures opening into the fire-box, means for supplying said gas-head with superheated or gasified steam, a water vessel or conduit on said gas-head above and adjacent to the said jet-apertures, and pipes connecting said conduit at one side with the water-base and at the other side with the water-space in the boiler, substantially as set forth.

5. The combination with the boiler, the furnace under the same, the gas-head at the front of the combustion-chamber, the superheating-pipes about the combustion-chamber and connected at one end with the boiler and at the other end with said gas-head, and the burning-jet on said gas-head, as and for the purpose set forth.

6. A furnace having a gas-head 26, in the front wall of its fire-box, zigzag steam-pipes 34 and 36 extending from the front of the fire-box back to the bridge-wall at the sides of the fire-box, the pipe 35 on the bridge-wall connecting said pipes 34 and 36, and the pipe 37 connecting the pipe 36 with the gas-head, in combination with a boiler over the furnace, and a pipe connecting the steam-space in the boiler with the pipe 34, substantially as set forth.

705,961. REVERSING MECHANISM. ROLLEND R. RICE, Marysville, Pa. Filed Oct. 30, 1901. Serial No. 80,537. (No model.)



Claim.—1. A reversing mechanism, comprising a loose pulley, a driven shaft, a stationary shaft, split clutch-rings carried by the pulley, gear-wheels, of which one is secured to the driven shaft and the other is mounted to rotate loosely on the stationary shaft, the said gear-wheels being adapted to be engaged by the said clutch-rings, a carrier secured to the stationary shaft, pinions on the said carrier and in mesh with the said gear-wheels, and means for opening and closing the said clutch-rings, as set forth.

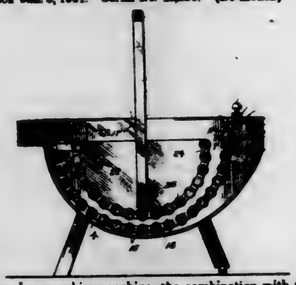
2. A reversing mechanism, comprising a loose pulley, a driven shaft, a stationary shaft, split clutch-rings carried by the pulley, gear-wheels, of which one is secured to the driven shaft and the other is mounted to rotate loosely on the stationary shaft, the said gear-wheels being adapted to be engaged by the said clutch-rings, a carrier secured to the stationary shaft, pinions on the said carrier and in mesh with the said gear-wheels, means for opening and closing the said clutch-rings, the said means comprising cams engaging the ends of the split clutch-rings, shifting cones under the control of the operator, and arms engaging the shifting cones and secured on the shafts of the said cams, as set forth.

3. A reversing mechanism, comprising a loose pulley, a driven shaft, a stationary shaft, split clutch-rings carried by the pulley, gear-wheels, of which one is secured to the driven shaft and the other is mounted to rotate loosely on the stationary shaft, the said gear-wheels being adapted to be engaged by the said clutch-rings, a carrier secured to the stationary shaft, pinions on the said carrier and in mesh with the said gear-wheels, means for opening and closing the said clutch-rings, the said means comprising cams engaging the split ends of the said clutch-rings, cam-shafts carrying the cams and journaled in the webs of the said pulley, arms on the said cam-shafts, pins adjustable in the said arms, and shifting cones slidable on the said shafts and engaged by the said pins, as set forth.

4. A reversing mechanism comprising a loose pulley, a driven shaft, a stationary carrier, pinions journaled thereon, beveled gear-wheels in mesh with opposite sides of the said pinions, one of the said gear-wheels being secured on the said driver shaft and the other being mounted to rotate loosely, and means for locking either of the said gear-wheels to the said pulley, as set forth.

5. A reversing mechanism comprising a loose pulley, a driven shaft, a stationary carrier, pinions journaled thereon, beveled gear-wheels in mesh with opposite sides of the said pinions, one of the said gear-wheels being secured on the said driven shaft and the other being mounted to rotate loosely, and means for locking either of the said gear-wheels to the said pulley, the said means comprising split clutch-rings secured to the pulley and adapted to engage the solid gear-wheels, cams for opening or closing the said split clutch-rings, and manually-controlled means for actuating the said means, as set forth.

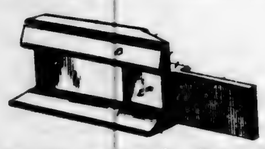
705,962. WASHING-MACHINE. JOHN B. KEYSER, Manchester, Pa. Filed Jan. 5, 1901. Serial No. 42,239. (No model.)



Claim.—In a washing-machine, the combination with the semicylindrical tub having an extended end, a semicylindrical stationary rubber pivoted at one end to the sides of the tub and adapted to rest upon the extended end when thrown out of engagement with the tub, the angular bearing-plates secured to the sides of the tub having one portion vertical and the other outwardly curved, links having their outer ends pivoted to the sides of the tub and their inner end provided with eyes, of a semicylindrical reciprocating rubber having trunnions detachably connected to the eyes of the links and adapted to rest in the bearing-plates, substantially as specified.

705,963. RAILROAD-RAIL JOINT. CHRIS BRANDS, Fredonia, Kans., assignor of one-third to William T. Stroud, Fredonia, Kans. Filed Feb. 4, 1902. Serial No. 92,771. (No model.)

Claim.—1. A railroad-joint comprising rail-terminals, one of which has a centrally-projecting tongue and a head cut back to clear the upper portion of the flange and form a table, and the other terminal formed with a longitudinal slot in the web and flange and a head projected beyond the end of said web and flange, the meeting portions of the rail-heads being scarfed.



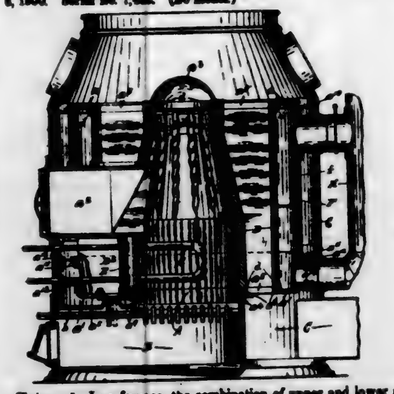
2. A railroad-joint comprising rail-terminals, one of which is transversely cut through to remove a portion of the head, web and flange to provide a longitudinally-projecting tongue having a vertical extent equal to the combined height of the flange and web at the center, the head being cut back from the point of intersection of the tongue with the web and flange, and the other terminal having a longitudinally-extending slot in the web and flange at the center and the head projected beyond the end of the flange and web to extend over the flange of the adjacent rail-terminal, the ends of the heads having interlocking relation and shaped to form a scarf-joint.

705,964. STOVEPIPE-HOLDER. JOSEPH A. RHODES, East Las Vegas, N. Mex. Filed Sept. 9, 1901. Serial No. 74,237. (No model.)

Claim.—1. The herein-described stovepipe-holder, consisting of an open band of bendable material and having an outwardly-extending arm at each end, one of the arms being provided with a longitudinal slot, a bolt carried by the short arm passed through the slot of the long arm and provided with a nut, corrugated stationary limb members projecting from opposite sides of the band, corrugated extension limb members overlapping a portion of the stationary limb members and provided with hooks at their ends, and a sleeve on the overlapped portions of the said limb members, as set forth.

2. A stovepipe-holder, comprising an open band of bendable material, arms on ends of the band, one arm having a longitudinal slot, a screw-bolt and nut on the other arm, the bolt passing through the slot and the nut clamping the arms toward each other, and two limbs adjustable for length having hooks on outer ends, and projecting from the band at one edge thereof.

705,965. FURNACE. ELMER O. RICHARD, Syracuse, N. Y., assignor to the Kelsey Furnace Company, Syracuse, N. Y. Filed Mar. 6, 1900. Serial No. 7,668. (No model.)



Claim.—1. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, the lower plate being provided with an upwardly-extending flange, a tubular shell interposed between the upper plate and the upwardly-extending flange of the lower plate, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell at the inner side of the upwardly-extending flange of the lower plate and communicating with the openings in said plates, and a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being detachably mounted on the lower plate within the tubular shell at the inner side of said upwardly-extending flange and between two of the air-heating conduits, substantially as and for the purpose specified.

3. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, the upper plate being provided with a downwardly-extending flange of less diameter than said plate, and the lower plate being provided with an upwardly-extending flange having a peripheral shoulder, a tubular shell surrounding the depending flange on the upper plate and the upper portion of the flange on the lower plate, and interposed between the upper plate and the peripheral shoulder of the flange on the lower plate, upright air-heating conduits forming the upright wall of a part of the combustion-chamber, said conduits being arranged between the upper and lower plates within the tubular shell at the inner sides of said flanges of the upper and lower plates and communicating with the openings in said plates, and a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being mounted on the lower plate within the tubular shell at the inner side of the upwardly-extending flange of said lower plate and between two of the air-heating conduits, substantially as set forth.

4. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, a tubular shell interposed between the upper and lower plates, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell and communicating with the openings in said plates, a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being arranged within the tubular shell between two of the air-heating conduits, and a supplemental water-heating chamber projecting from the inner face of the former water-heating chamber into said combustion-chamber, substantially as and for the purpose set forth.

5. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, the lower plate being provided with an upwardly-extending flange, a tubular shell interposed between the upper plate and the upwardly-extending flange of the lower plate, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell at the inner side of the upwardly-extending flange of the lower plate and communicating with the openings in said plates, a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being detachably mounted on the lower plate within the tubular shell at the inner side of said upwardly-extending flange and between two of the air-heating conduits, and a supplemental water-heating chamber projecting from the inner face of the former water-heating chamber into said combustion-chamber, substantially as and for the purpose described.

6. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, a tubular shell interposed between the upper and lower plates, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell and communicating with the openings in said plates and having the lower portions of their contiguous sides formed substantially flat and engaged with each other, and the upper portions of said sides corrugated and separated, and a water-heating chamber also forming the upright wall of a part of said combustion-chamber and arranged within the tubular shell between two of the air-heating conduits, substantially as and for the purpose specified.

7. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, the lower plate being

ing conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell and communicating with the openings in said plates, and a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being arranged within the tubular shell between two of the air-heating conduits, substantially as and for the purpose described.

2. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, the lower plate being provided with an upwardly-extending flange, a tubular shell interposed between the upper plate and the upwardly-extending flange of the lower plate, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell at the inner side of the upwardly-extending flange of the lower plate and communicating with the openings in said plates, and a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being detachably mounted on the lower plate within the tubular shell at the inner side of said upwardly-extending flange and between two of the air-heating conduits, substantially as and for the purpose specified.

3. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, the upper plate being provided with a downwardly-extending flange of less diameter than said plate, and the lower plate being provided with an upwardly-extending flange having a peripheral shoulder, a tubular shell surrounding the depending flange on the upper plate and the upper portion of the flange on the lower plate, and interposed between the upper plate and the peripheral shoulder of the flange on the lower plate, upright air-heating conduits forming the upright wall of a part of the combustion-chamber, said conduits being arranged between the upper and lower plates within the tubular shell at the inner sides of said flanges of the upper and lower plates and communicating with the openings in said plates, and a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being mounted on the lower plate within the tubular shell at the inner side of the upwardly-extending flange of said lower plate and between two of the air-heating conduits, substantially as set forth.

4. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, a tubular shell interposed between the upper and lower plates, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell and communicating with the openings in said plates, a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being arranged within the tubular shell between two of the air-heating conduits, and a supplemental water-heating chamber projecting from the inner face of the former water-heating chamber into said combustion-chamber, substantially as and for the purpose set forth.

5. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, the lower plate being provided with an upwardly-extending flange, a tubular shell interposed between the upper plate and the upwardly-extending flange of the lower plate, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell at the inner side of the upwardly-extending flange of the lower plate and communicating with the openings in said plates, a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being detachably mounted on the lower plate within the tubular shell at the inner side of said upwardly-extending flange and between two of the air-heating conduits, and a supplemental water-heating chamber projecting from the inner face of the former water-heating chamber into said combustion-chamber, substantially as and for the purpose described.

6. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, a tubular shell interposed between the upper and lower plates, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell and communicating with the openings in said plates and having the lower portions of their contiguous sides formed substantially flat and engaged with each other, and the upper portions of said sides corrugated and separated, and a water-heating chamber also forming the upright wall of a part of said combustion-chamber and arranged within the tubular shell between two of the air-heating conduits, substantially as and for the purpose specified.

7. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, the lower plate being provided with an upwardly-extending flange, a tubular shell interposed between the upper plate and the upwardly-extending flange of the lower wall, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell at the inner side of the upwardly-extending flange of the lower plate and communicating with the openings in said plates, a water-heating chamber also forming the upright wall of a part of said combustion-chamber, said water-heating chamber being detachably mounted on the lower plate within the tubular shell at the inner side of said upwardly-extending flange and between two of the air-heating conduits, and water-circulating pipes connected to the water-heating chamber, one of the pipes being arranged above said upwardly-extending flange, and the other being passed through said flange, substantially as and for the purpose set forth.

8. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, the lower plate being provided with an upwardly-extending flange, a tubular shell interposed between the upper plate and the upwardly-extending flange of the lower plate, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell and communicating with the openings in said plates, a water-heating chamber also forming the upright wall of a part of said combustion-chamber, said water-heating chamber being detachably mounted on the lower plate within the tubular shell at the inner side of said upwardly-extending flange and between two of the air-heating conduits, a supplemental water-heating chamber projecting from the inner face of the former water-heating chamber into said combustion-chamber, and water-circulating pipes connected to the water-heating chamber, one of the pipes being arranged above said upwardly-extending flange, and the other being passed through said flange, substantially as and for the purpose described.

9. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, a tubular shell interposed between the upper and lower plates, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell and communicating with the openings in said plates, a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being arranged within the tubular shell between two of the air-heating conduits, and an air-heating chamber arranged within the tubular shell at the outer side of the water-heating chamber, substantially as and for the purpose specified.

10. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, the lower plate being provided with an upwardly-extending flange, a tubular shell interposed between the upper plate and the upwardly-extending flange of the lower wall, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell at the inner side of the upwardly-extending flange of the lower plate and communicating with the openings in said plates, a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being detachably mounted on the lower plate within the tubular shell at the inner side of said upwardly-extending flange and between two of the air-heating conduits, and an air-heating chamber arranged within the tubular shell between said upwardly-extending flange and the water-heating chamber, substantially as and for the purpose set forth.

11. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough, the lower plate being provided with an upwardly-extending flange, a tubular shell interposed between the upper plate and the upwardly-extending flange of the lower plate, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell at the inner side of the upwardly-extending flange of the lower plate and communicating with the openings in said plates, a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being detachably mounted on the lower plate within the tubular shell at the inner side of said upwardly-extending flange and between two of the air-heating conduits, an air-heating chamber arranged within the tubular shell between said upwardly-extending flange and the water-heating chamber, a supplemental water-heating chamber projecting from the inner face of the former water-heating chamber into said combustion-chamber, and water-circulating pipes passed through the air-heating chamber and connected to the water-heating chamber, one of the pipes being arranged above said upwardly-extending flange, and the other being passed through said flange, substantially as and for the purpose described.

12. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough and aligned with each other, the lower plate being provided with an upwardly-extending flange formed with an opening extending horizontally therethrough, a tubular shell interposed between the upper plate and the upwardly-extending flange of the lower plate, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell at the inner side of the upwardly-extending flange of the lower plate and communicating with the openings in said plates, a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being detachably mounted on the lower plate within the tubular shell at the inner side of said upwardly-extending flange and between two of the air-heating conduits, and an air-heating chamber arranged within the tubular shell between said upwardly-extending flange and the water-heating chamber and formed with upper and lower openings communicating with one of the openings extending vertically through the lower plate and with the openings extending horizontally through the upwardly-extending flange of said lower plate, substantially as and for the purpose specified.

13. In a furnace, the combination of upper and lower separable plates having openings extending vertically therethrough and aligned with each other, the lower plate being provided with an upwardly-extending flange formed with an opening extending horizontally therethrough, a tubular shell interposed between the upper plate and the upwardly-extending flange of the lower plate, upright air-heating conduits forming the upright wall of a part of the combustion-chamber of the furnace, said conduits being arranged between the upper and lower plates within the tubular shell at the inner side of the upwardly-extending flange of the lower plate and communicating with the openings in said plates, a water-heating chamber also forming the upright wall of a part of the combustion-chamber, said water-heating chamber being detachably mounted on the lower plate within the tubular shell at the inner side of said upwardly-extending flange and between two of the air-heating conduits, an air-heating chamber arranged within the tubular shell between said upwardly-extending flange and the water-heating chamber and formed with upper and lower openings communicating with one of the openings extending vertically through the lower plate and with the opening extending horizontally through the upwardly-extending flange of said lower plate, and water-circulating pipes passed through the air-heating chamber and connected to the water-heating chamber, one of the pipes being arranged above said upwardly-extending flange, and the other being passed through the opening extending horizontally through said flange, substantially as and for the purpose set forth.

705,966. TOY BUBBLE-BLOWER. LUELLEN H. ROCKWELL, Mount Carmel, Pa., assignor of one-half to William M. Kramer, Mount Carmel, Pa. Filed Mar. 19, 1902. Serial No. 98,986. (No model.)

Claim.—1. A bubble-blower comprising a blowing element, a body with a reservoir therein, and a bubble-forming head having a bell-mouth with a filling of saponaceous material, the head and blowing element having bores practically continuous with each other.

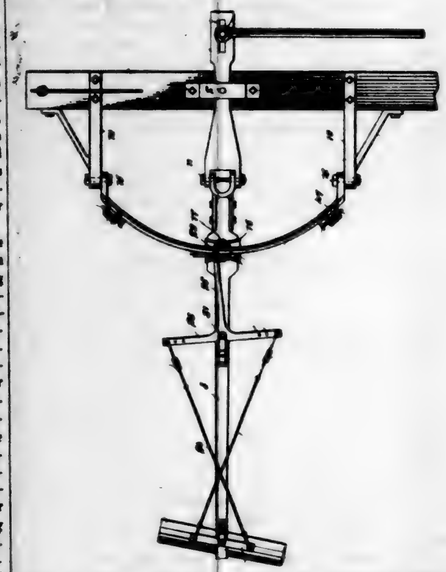
2. A bubble-blowing toy comprising a blowing element, a body with a reservoir therein, and a bubble-forming head, the blowing element having a mouthpiece and a stem with a bore therethrough, the said stem extending through the reservoir of the body and engaging the inner end of the head and the latter provided with a bore, and a bell-mouth having a saponaceous filling.

3. A bubble-blowing toy comprising a blowing element, an intermediate body having a reservoir, and a bubble-forming head, the said parts being frictionally engaged and disposed in longitudinal alinement, the head and blowing element having bores therethrough which are practically continuous with each other.

4. A bubble-blowing toy comprising a blowing element having a mouthpiece and a stem with a bore therethrough, the free end of the stem being reduced, an intermediate body having a reservoir through which the stem extends, and a bubble-forming head engaged by the one end of the body and having a bore therethrough and also provided with a mouth supplied with a saponaceous filling, the free end of the stem being adapted to engage the end of the head within the body.

705,967. AUTOMATIC CURRENT-MOTOR. JOHN ROSE, Greenville Wash. Filed July 15, 1901. Serial No. 67,999. (No model.)

Claim.—1. In a current-motor, the combination of a track, an oscillatory member engaging the said track, bumpers located on either end of said track, and a slide on said oscillatory member and adapted to strike the said bumpers as the oscillatory member moves along the said track, a blade pivoted upon said oscillatory member, and flexible connections between said blade and said slide for the purpose of shifting the angle of said blade when said slide engages said bumpers.



2. In a current-motor, the combination of an oscillatory member, a pivoted track engaging the said oscillatory member, a trolley adapted to move on said track and connect the same with the said oscillatory member, bumpers located on either end of said track, and a slide having a tripping mechanism positioned so as to meet said bumpers.

3. In a current-motor, the combination of a blade, an oscillatory member carrying the said blade, a swinging member mounted on the said oscillatory member and connected to the said blade, a slide also mounted on the said oscillatory member and connected to the said swinging member, a pivoted track engaging the said member, and bumpers located on either end of the said track and adapted to coöperate with the said sliding member to control the position of the said blade.

4. In a current-motor, the combination of a blade, an oscillatory member carrying the said blade, a swinging member connected to the said blade, a slide carried on the said oscillatory member, a pivoted member connected to the said oscillatory member, a support therefor, and a pair of bumpers adapted to control the position of the said slide.

5. In a current-motor, the combination of a blade, a slide connected thereto, pawls carried by said slide, and a rack moving under said pawls, whereby the position of the said blade is controlled.

6. In a current-motor, the combination of an oscillatory member, a swinging member mounted on the said oscillatory member, a slide connected to said swinging member and having pawls, a pair of bumpers adapted to operate on the said pawls, and a rack carried by the said oscillatory member, whereby the position of the said swinging member with respect to the said oscillatory member is controlled.

7. In a current-motor, the combination of an oscillatory member, racks and a slide carried by the said oscillatory member, pawls mounted on the said slide, and bumpers adapted to coöperate with the said pawls to control the position of the said sliding member.

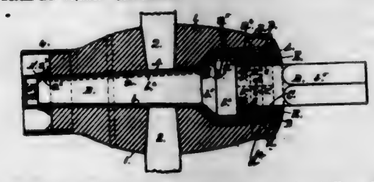
8. In a current-motor, the combination of an oscillatory member, a movable member carried thereby, pawls mounted on said movable member, trips connected to said pawls, racks to be engaged by said pawls, and a pair of bumpers adapted to operate upon the said trips and the said movable member to control their positions with respect to the said oscillatory member.

9. The combination in a current-motor, of a blade, a swinging member connected to said blade, a slide having pawls and trips adapted to control the position of the said swinging member, racks to be engaged by said pawls, a pivoted track, and bumpers mounted on said track whereby the blade is swung into a different position at each end of its stroke.

10. An automatic current-motor, comprising a swinging arm pivoted upon a center and provided with a trolley, an arc-shaped track concentric to said center and engaging said trolley, a blade mounted upon said swinging arm and movable relatively thereto, and means for periodically shifting the position of said blade relatively to the said arm.

11. An automatic current-motor, comprising a swinging arm pivoted upon a center, a blade mounted upon said arm and movable relatively thereto, levers and connections for periodically moving said blade relatively to said arm, and bumpers for actuating said levers and connections.

705,968. VEHICLE-WHEEL SPINDLE. BLAIR B. ROOT, Lancaster, Pa., assignor to John F. Hess, Lancaster, Pa. Filed Oct. 2, 1901. Serial No. 77,269. (No model.)



Claim.—1. The combination in a vehicle-wheel spindle and bearing, with the box, A, having the rearwardly-widening portion, *a*, the outwardly-sloping conical portion, *a'*, with the thickened wall, and the rearwardly-extending cylindrical portion, a^2, having the internal screw-thread, a^3, with means provided for securing it axially to a wheel-hub, of the spindle, B, seated in said box, said spindle having the rearwardly-widening portion, *b*, the outwardly-sloping conical portion, *b'*, the rearwardly-extending cylindrical portion, b^1, having the abrupt shoulder, b^2, and the cylindrical portion, b^4, having the angular rear end portion, b^5, with means provided, such as a divided screw, to revokably hold said spindle in place, substantially as and for the purpose hereinbefore set forth.

2. The combination in a vehicle-wheel spindle and bearing, with the box, A, as described, axially secured to a wheel-hub as shown, and the spindle, B, as described, seated in said box as shown, said box having the internal screw-thread, a^3, and said spindle having the abrupt shoulder, b^2, with the cylindrical portion, b^4, of the divided screw, C, with the external screw-thread, *c*, sleeved on said portion, b^4, screwed into said box and against said shoulder, b^2, substantially as described and for the purpose hereinbefore set forth.

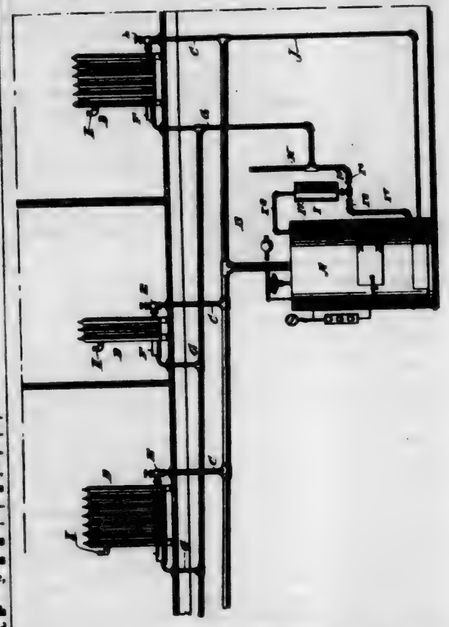
3. In a vehicle spindle and bearing with the box, A, as described axially secured to a wheel-hub as shown, and the spindle, B, as described seated in the box as shown; said box having the internal screw-thread, a^3, and said spindle the abrupt shoulder, b^2, with the cylindrical portion, b^4; the divided screw, C, with the external screw-thread, *c*, sleeved on said portion, b^4, screwed into said box and against said shoulder, b^2; said screw, C, having the diametrical longitudinal cuts, *c'*, making the sections, c^2 c^2, with the notches, c^4, and the projections, c^5, engaging said notches, and with means provided to lock said screw, C, in place; all substantially as described and for the purpose hereinbefore set forth.

4. In a vehicle-wheel spindle and bearing, with a hub, I, having the box, A, as described, axially secured into said hub, the spindle, B, as described journaled in said box, and the screw, C, as described screwed therein and against the shoulder, b^2; the ring screw, D, with the internal screw-thread, *d*, screwed onto said screw, C, and against the rear end of said box, substantially as described and for the purpose hereinbefore set forth.

705,969. STEAM-HEATING SYSTEM. WILLIS E. ROYS, Richmond Hill, N. Y., assignor to Margaret T. Roys, New York, N. Y. Filed Nov. 18, 1900. Serial No. 36,625. (No model.)

Claim.—A gravity steam system, comprising a steam-generator, a plurality of radiators, steam-supply connections between the generator and the said radiators, steam-admission and temperature-controlling devices in the said connections adjacent to the radiators, each controlling device serving to regulate the amount of steam passing to its particular radiator and to control the degree of heat to which the room is to be heated, a water-of-condensation-disposing device connected with each radiator and arranged to receive and discharge the accumulating water of condensation from the radiator independently of said controlling device and irrespective of the pressure in the radiator, said water-of-condensation-disposing device preventing escape of steam from the radiator and a return connection between the said water-of-condensation-disposing device and the said generator, to return the water of condensation to the generator, said return connection containing a pressure-relief device open to the atmosphere, and an automatic return device between the said generator and the said relief device, as set forth.

705,969.



705,970. SOLAR ATTACHMENT FOR TRANSIT INSTRUMENTS. ORVILLE F. SHATTUCK, Denver, Colo. Filed Nov. 14, 1901. Serial No. 82,206. (No model.)

Claim.—1. In a solar attachment for transit, theodolite or similar instruments, the combination with the telescope, of two reflectors mounted to rotate about the objective extremity of the telescope while the latter remains stationary, and arranged to reflect a ray of light twice, substantially as described.

2. In an instrument of the class described, the combination with the telescope, of a bracket revolubly mounted on the objective extremity of the instrument and composed of two parallel side pieces, two reflectors mounted between the parallel members of the bracket and arranged to reflect a ray of light twice before entering the objective of the telescope.

3. In an instrument of the class described, the combination with the telescope, of a bracket revolubly mounted on the objective extremity of the telescope and composed of two parallel sides pieces, and two reflectors mounted between the sides of the bracket, one being fixed and the other movable to vary the angle between them, substantially as described.

4. The combination with the telescope of a transit, theodolite or similar instrument, of a reflector-holder revolubly mounted on the objective extremity of the telescope, two reflectors mounted on said holder and turning therewith, the reflectors being arranged at suitable angles to each other to reflect a ray of light twice, suitable means for regulating one of the reflectors to vary their angle, and suitable means for rotating the reflector-holder on the telescope, substantially as described.

5. The combination with the telescope of a transit, theodolite or similar instrument, of a reflector-holder revolubly mounted on the objective extremity of the telescope, two reflectors mounted on said holder and turning therewith, the reflectors being arranged at suitable angles to each other to reflect a ray of light twice, the second reflection being in the line of the optical axis of the telescope, and suitable means for regulating one of the reflectors to vary their angles for the purpose set forth.

6. The combination with the telescope of a transit or similar instrument, of a reflector-holder revolubly mounted on the objective extremity

of the telescope, two reflectors mounted on said holder and arranged to twice reflect a ray of light, the second reflection being in line of the optical axis of the telescope, one of the reflectors being pivotally mounted, and a differentially-threaded nut mounted to regulate the position of the pivoted reflector for the purpose set forth.

7. The combination with the telescope of a transit or similar instrument, of a bracket revolubly mounted to project beyond the objective of the telescope, two reflectors mounted on said bracket, one of them being fixed and crossing the line of sight of the telescope at a suitable angle, and the other being arranged at a suitable angle to the first and pivotally connected with the bracket, and a differentially-threaded nut suitably mounted for regulating the position of the pivoted reflector to vary its angle with the fixed reflector, substantially as described.

8. The combination with the telescope of a transit or similar instrument, of a bracket revolubly mounted to project beyond the objective of the telescope, two reflectors mounted on said bracket, one of them being fixed, and the other being arranged at a suitable angle to the first, and pivotally connected with the bracket, a differentially-threaded nut suitably mounted for regulating the position of the pivoted reflector to vary its angle with the fixed reflector, the said nut having a graduated head, substantially as described and for the purpose set forth.

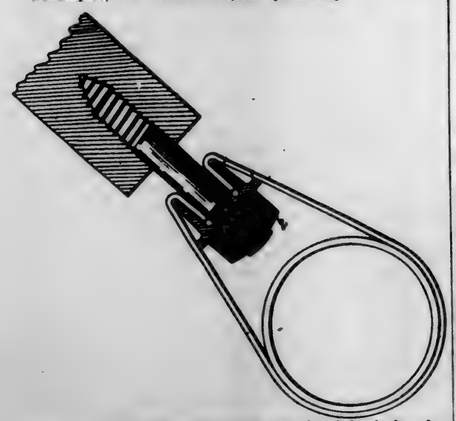
9. The combination with the telescope of an instrument of the class described, of a bracket mounted to project beyond the objective of the telescope, two reflectors mounted on said bracket and arranged to form a suitable angle with each other, one of the said reflectors being pivotally connected with the bracket, a differentially-threaded nut suitably mounted for regulating the position of the pivoted reflector, the head of said nut being graduated for the purpose set forth, and a spring-held pointer mounted on the bracket and engaging the head of said nut, substantially as described.

10. The combination with the telescope of a transit or similar instrument, of a bracket revolubly mounted on the objective extremity of the telescope and projecting beyond the same, two reflectors mounted on said bracket and arranged at a suitable angle to each other, and suitable means for rotating the reflector-carrying bracket, substantially as described.

11. The combination with the telescope of a transit or similar instrument, of a reflector-holder revolubly mounted on the objective extremity of the telescope and projecting forward therefrom, two reflectors mounted on said reflector-holder and arranged to rotate therewith, the two reflectors being arranged to form an angle with each other and also arranged to twice reflect a ray of light, the second reflection being in line of the optical axis of the telescope, one of the reflectors being movably mounted, and a screw mounted on the reflector-holder, to regulate the position of the movable reflector for the purpose set forth.

12. The combination with the telescope of a transit, theodolite, or similar instrument, of a reflector-holder revolubly mounted on the objective extremity of the telescope, two reflectors mounted on said holder and turning therewith, the reflectors being arranged at suitable angles to each other to reflect a ray of light twice, suitable means for rotating the reflector-holder on the telescope, and suitable means for locking said holder in any desired position of adjustment, substantially as described.

705,971. PIPE-HANGER. CHARLES W. SHARP, Carbondale, Ill. Filed Sept. 9, 1901. Serial No. 74,720. (No model.)



Claim.—1. A pipe-hanger consisting of a threaded rod adapted to be screwed in a stationary support, and a washer provided with a flange and adjustably carried by said rod, in combination with a metallic strap or support bent to form a loop for receiving the pipe, and its ends bent and held within the washer between the flange and the rod, and a nut for supporting the washer, substantially as specified.

2. A pipe-hanger consisting of a rod having both its ends threaded, a washer removably carried thereby provided with a flange, a strap bent into the form of a loop to support the pipe, hooks formed on the end of the strap and engaging the flange of the washer, and a nut placed upon the rod beneath the washer for supporting and adjusting the same, substantially as specified.

705,972. MOLD FOR ARTIFICIAL TEETH. THOMAS STEELE, Redbank, N. J. Filed Dec. 5, 1901. Serial No. 84,737. (No model.)

Claim.—1. A mold for artificial teeth, having a core-bar, heads hold adjustably thereon, and core-pins projecting rigidly from the said heads, as set forth.

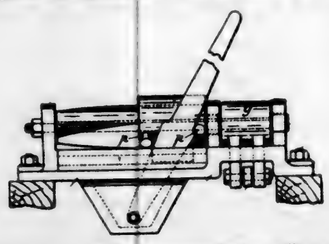
2. A mold for artificial teeth, having a core-bar, heads hold adjustably thereon, core-pins on the said heads, and means for adjustably securing the heads to the core-bar, the heads having shanks provided with elongated slots, and screws extending through the slots and screwing in the core-bar for securing the shank to the core-bar, as set forth.

3. A mold for artificial teeth, having a core-bar provided with recesses, heads carrying the pins and having shanks extending into the recesses of the core-bar, each shank having an elongated slot and a countersink, and a screw passing through the slot and screwing into the core-bar, the head of the screw extending in the said countersink, as set forth.

705,973. COUPLING FOR CONNECTING HANDLES TO TOOLS. WILLIS A. SUTTLE, Austin, Tex. Filed Apr. 17, 1902. Serial No. 103,443. (No model.)

Claim.—In a device of the character described, the combination with a sleeve having communicating vertical and horizontal slots disposed one above the other, of a tang having transversely-projecting shoulders one arranged above the other, and a cuff having a tapering end to coact with the lower end of the sleeve and the lowermost shoulder to hold the uppermost shoulder in the horizontal slot, substantially as set forth.

705,974. SHUNTING-LEVER. WILLIAM TAYLOR, Sandiacre, England. Filed Apr. 15, 1902. Serial No. 102,984. (No model.)



Claim.—1. In a shunting-lever or switching appliance, the combination of a helical element provided with a slot, a cylindrical element or piece in alinement therewith and provided with a slot, and a flat axle-bar passing through the slot in both said elements, said flat axle-bar being capable of a slight torsion at one end only, thereby permitting the said cylindrical element to move independently of the helical element.

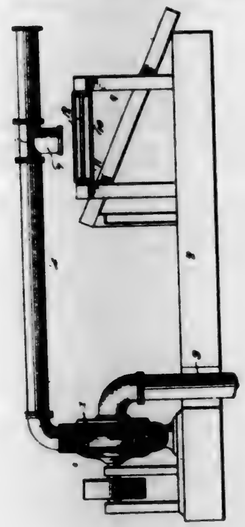
2. In a shunting-lever or switching appliance, the combination of a helical element provided with a tapering slot, a cylindrical element separate therefrom but in alinement therewith and provided with a tapering slot, and a flat axle-bar passing through said slots and held at one end only but capable of slight torsion at the other end, so permitting the cylindrical element to move without influencing the helical element.

3. In a shunting-lever or switching appliance, the combination of a helical element provided with a tapering double-ended keyhole-slot, a cored nut adapted to traverse the same and provided with means for preventing its rotation, a cylindrical element in alinement with said helical element but capable of a movement independent of the helical element, said cylindrical element provided with a tapering double-ended keyhole-slot, and a flat axle-bar passing through the slots and on which bar said elements are mounted, said bar being held firmly at one end only but capable of slight torsion at the other end, and means for operating said shunting-lever or switching appliance.

4. In a shunting-lever or switching appliance, the combination of a helical element provided with a double-ended tapering keyhole-slot extending axially therethrough, a traveling nut mounted thereon, a lever for operating said nut, a cylindrical element in alinement with said helical element and provided with a double-ended tapering keyhole-slot extending axially therethrough, a flat axle-bar passing loosely through said slots, a slotted bush mounted between the helical and the cylindrical elements and supported in an intermediate bearing, the ends of said axle-bar being mounted in end bearings in a manner to permit the cylindrical element to move independently of the helical element, by a slight torsion on one end of said axle-bar.

5. In a shunting-lever or switching appliance comprising a helical element provided with a tapering double-ended keyhole-slot extending axially therethrough, a cored nut adapted to traverse the same, a lever operating said nut, a cylindrical element in alinement with said helical element provided with a tapering double-ended keyhole-slot extending axially therethrough, a bush arranged between said elements and provided with a tapering double-ended keyhole-slot extending axially therethrough, the flat axle-bar, formed with a cylindrical head at one end and with a screw-threaded portion at the other end, adapted to pass through said elements and bush, and bearings to support the ends of said axle-bar.

705,975. CLAM OR OYSTER DREDGE. WILLIAM A. THOMPSON, La Crosse, Wis. Filed Oct. 22, 1901. Serial No. 80,301. (No model.)



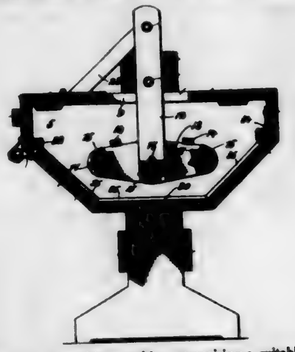
Claim.—1. A dredge having a discharge-conduit provided with a depending discharge branch, and a screen beyond the latter, whereby material carried through the conduit to the screen, will by its own gravity drop through the depending discharge branch, substantially as described.

2. A dredge having a discharge-conduit provided with a discharge branch and a screen beyond the latter, in combination with a screen onto which said branch discharges, substantially as described.

3. A dredge having a discharge-conduit provided with a discharge branch and a screen beyond the latter, in combination with an endless traveling carrier-screen onto which said branch discharges, substantially as described.

4. A dredge having a discharge-conduit provided with a discharge branch and a screen beyond the latter, in combination with a carrier-screen onto which said branch discharges, a chute under said carrier-screen to discharge the material that passes through the latter and a chute on which the material carried by said carrier is discharged by the latter, substantially as described.

705,976. WASHING-MACHINE. GEORGE THOMAS, Gothenburg, Nebr. Filed Mar. 25, 1902. Serial No. 99,891. (No model.)



Claim.—1. A washing-machine, comprising a suitable supporting-frame, a pivoted ends-box, a pivotal shaft supported in stationary bearings on said ends-box, a rubber pivoted in the supporting-frame above the pivots of said box, and links connecting the pivoted rubber with the pivotal shaft on the ends-box.

2. A washing-machine, comprising a supporting-frame, having the slotted bearings at its upper portion, a ends-box pivotally supported in said frame at points below said bearings thereof, a rubber having the arms provided with the fulcrum-shaft and the connecting-rod, said fulcrum-shaft being removably mounted in the slotted bearings of the supporting-frame, another shaft mounted in stationary bearings on an end portion of the ends-box, and connecting arms or links between the last-mentioned shaft and the connecting-rod at the upper ends of the rubber-arms.

3. A washing-machine having a frame, a ends-box pivoted thereto, means for swinging said ends-box, a rubber pivoted to the frame in eccentric relation and independently of the ends-box and adapted to swing in an arc eccentric to the path of said ends-box, and links pivoted to the rubber and to the ends-box and communicating the motion of the latter to said rubber.

705,977. METHOD OF PRODUCING FIGURED PILE FABRIC. OTTO THIER, New York, N. Y. Filed Dec. 4, 1901. Serial No. 84,671. (No specimens.)

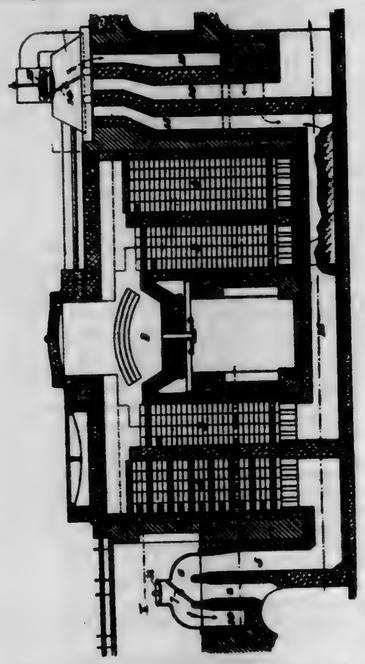
Claim.—The herein-described method for producing figured pile fabrics, consisting essentially in subjecting a portion of the pile of a plain, woven pile fabric to the action of colors to color this portion of the pile according to a predetermined design, at the same time subjecting the remaining portion of the pile to the action of a pile-destroying medium, then steaming the fabric to fix the color applied and to aid in the final destruction of that portion of the pile treated with the pile-destroying medium, and finally removing the destroyed pile from the fabric, as set forth.

705,978. REGENERATIVE FURNACE. FRANCIS H. TERRY, Pittsburg, Pa. Filed Nov. 14, 1901. Serial No. 82,318. (No model.)

Claim.—1. A regenerative furnace having air and gas regenerators on each side thereof, reversing-valves on opposite sides of the furnace, and a flue leading from one regenerator on each side to the reversing-valve on the side opposite the said regenerator; substantially as described.

2. A regenerative furnace having gas and air regenerators arranged in pairs on each side thereof, a reversing air-valve on one side, a reversing gas-valve on the other side, one of each pair of regenerators having a flue leading beneath the furnace to the valve on the other side thereof, while the other of said pair has a flue connection to the valve on the same side; substantially as described.

3. A regenerative furnace having gas and air regenerators arranged in pairs on each side thereof, an air-valve casing on one side having three flues, one leading to the chimney-flue, another to the air-regenerator on the same side of the furnace, and the third leading to the air-regenerator on the opposite side of the furnace, and a gas-valve casing having three flues, one leading to the gas-regenerator on the same side, one to the chimney-flue, and the third to the gas-regenerator on the opposite side and reversing-valves within the valve-casings; substantially as described.



4. A regenerative furnace having a pair of regenerators on each side thereof, one of each pair being a gas-regenerator and the other an air-regenerator, three flues on one side of the furnace, one leading to the chimney-flue, another to the air-regenerator on the same side, and the third to the air-regenerator on the opposite side, three flues on the other side of the furnace, one a chimney-flue, the second leading to the gas-regenerator on the same side, and the third leading to the gas-regenerator on the opposite side, and valve mechanism for reversing the flow to the regenerators; substantially as described.

705,979. OVEN-SWAB. OSBRAVE W. TRESCHEL, Philadelphia, Pa. Filed Mar. 22, 1902. Serial No. 99,555. (No model.)

Claim.—1. A swab comprising a head having an opening in one end thereof, a link-bar projecting through the opening and secured to the head and a cloth-securing device carried by the link-bar.

2. A swab comprising a head, a casing on one end thereof and provided with a perforation, a headed link-bar projecting through the opening, and a cloth-securing device carried by the link-bar.

3. A swab comprising a head, a casing on one end thereof and provided with open sides and an opening in its end, a headed bar projecting through the opening in the end of the head, bars on the open sides of the head and a cloth-carrying device secured to the bar.

705,980. SHUTTLE-CHECKING MECHANISM FOR LOOMS. WALTER W. TWIST and WILLIAM H. BROOKHEAD, Fall River, Mass., assignors to Draper Company, Hopedale, Mass., a Corporation of Maine. Filed Oct. 5, 1901. Serial No. 77,620. (No model.)

Claim.—1. A shuttle-box, a spring-controlled binder having a fixed fulcrum adjacent the outer end of the box, and an impact member in pivotal connection with the binder and having a sliding fulcrum adjacent the mouth of the box, said impact member being normally maintained by the binder at an angle part way across the shuttle-path and constituting the movable wall of the shuttle-box.

2. A shuttle-box, and a shuttle-checking device comprising two oppositely-extended, juxtaposed members fulcrumed adjacent the inner and outer ends of the shuttle-box, respectively, and pivotally connected, one of said members having a sliding fulcrum, the inner of said members constituting the movable wall of the box, which is encountered by the shuttle as it enters the shuttle-box, and a spring to act upon the outer member and therethrough normally maintain the impact-face of the inner member partly across and at an acute angle to the shuttle-path.

3. A shuttle-box, and a shuttle-checking device comprising a spring-controlled, swinging member having a fixed fulcrum at its outer end, and a coöperating pivotally-connected impact member slidably supported at its inner end adjacent the mouth of the box, the impact member being normally maintained at an acute angle to and intersecting the shuttle-path.

4. A shuttle-box, and a shuttle-checking device comprising a spring-controlled, swinging member having a fixed fulcrum at its outer end, and a coöperating pivotally-connected impact member slidably supported at its inner end adjacent the mouth of the box, the impact member being normally maintained at an acute angle to and intersecting the shuttle-path, and means to limit the inward movement of the impact member.

5. A shuttle-box, and a shuttle-checking device comprising a spring-controlled member having a fixed fulcrum adjacent the outer end of the box, and a coöperating impact member having a sliding fulcrum at its inner end adjacent the mouth of the box and near its outer end pivotally connected with the spring-controlled member, the impact member having its elongated plane inner face normally maintained in the path of the shuttle at an angle thereto.

6. A shuttle-box, and a shuttle-checking device comprising a spring-controlled member, a juxtaposed and oppositely-extended impact member in pivotal engagement therewith near the outer end of the impact member, fulcra for said members adjacent the ends of the shuttle-box, the impact member being normally maintained in the path of the shuttle at an angle thereto, and a stop on the spring-controlled member to limit inward movement of the impact member.

7. A shuttle-box, and a shuttle-checking device comprising a spring-controlled member having a fixed fulcrum adjacent the outer end of the box, an impact member having a sliding fulcrum at its inner end, a rounded projection on one member to enter a socket in the adjacent face of the other member, to form a pivotal connection between them at or near the outer end of the impact member, and a stop on the spring-controlled member to coöperate with and limit inward movement of the impact member, the elongated, plane inner face of the latter being normally in the path of the shuttle at an acute angle thereto.

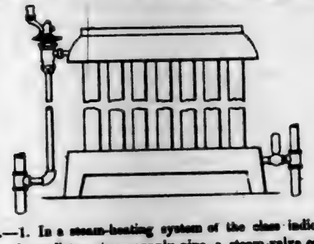
8. A shuttle-box, and a shuttle-checking device comprising a spring-controlled member having a fixed fulcrum adjacent the outer end of the box, and an impact member slidably supported at its end adjacent the mouth of the box, a lateral projection on one member to seat in a socket in the adjacent face of the other member, to form a pivotal connection between them adjacent the outer end of said impact member, the inner face of the latter being normally in the path of the shuttle at an angle thereto, engagement of the incoming shuttle with the impact member rocking it about its support and in turn rocking the coöperating member against its spring, the pressure of the impact member upon the shuttle gradually increasing as the latter approaches the outer end of the box and the inner face of the impact member parallels the shuttle side.

9. A shuttle-box, and a shuttle-checking device comprising a spring-controlled member having a fixed fulcrum adjacent the outer end of the box, and an impact member mounted to rock on said spring-controlled member and normally maintained with its inner elongated face in the path of the shuttle at an angle thereto, and a fixed support on which the inner end of the impact member can fulcrum and slide, the incoming shuttle simultaneously rocking the impact member upon the spring-controlled member and moving its inner end upon said fixed support, to thereby gradually increase the area of engagement between the impact member and the shuttle and the pressure upon the latter as it advances in the box.

10. In a loom, a spring-controlled protector rock-shaft, the lay having a shuttle-box, and a compound binder, comprising a member fulcrumed adjacent the outer end of the box and operatively connected with the said rock-shaft, and an impact member mounted at or near its outer end to rock on the first-mentioned member, and a fixed support for and on which the inner end of the impact member may slide, said impact member being normally maintained with its inner face in the path of the shuttle at an acute angle thereto.

11. A shuttle-box, and a shuttle-checking device, comprising an outer spring-controlled movable member, and a coöperating inner impact member, having a sliding fulcrum at its inner end, near the entrance of the shuttle-box, and bearing near its outer end upon said outer member, said impact member normally intersecting the shuttle-path.

705,981. LOW-PRESSURE STEAM-HEATER. FREDERIC TUDOR, Brookline, Mass. Filed June 13, 1901. Serial No. 64,494. (No model.)



Claim.—1. In a steam-heating system of the class indicated, the combination of a radiator, steam-supply pipe, a steam-valve controlling the admission of steam to the radiator, a return-pipe and connections therewith to the radiator, a manipulating-handle and associated actuating devices for the steam-valve having an opening movement which is limited within one revolution of the valve-handle, the valve and its actuating devices proportioned to admit to the radiator its maximum normal condensable quantity of steam before it reaches the limit of its opening movement, and constructed to indicate the arrival of the valve at the said point of maximum normally condensable steam delivery.

2. In a steam-heating system of the class indicated, the combination of a radiator, steam-supply pipe, a steam-valve controlling the admission of steam to the radiator, a return-pipe and connections therewith to the radiator, a manipulating-handle and associated actuating devices for the steam-valve having an opening movement which is limited within one revolution of the valve-handle, the valve and its actuating devices proportioned to admit to the radiator its maximum normal condensable quantity of steam before it reaches the limit of its opening movement, constructed to indicate the arrival of the valve at the said point of maximum normally condensable steam delivery, and to accelerate the final opening movement of the valve with relation to the rate of angular movement of the valve-handle.

3. In a steam-heating system of the class indicated, the combination of a radiator, a steam-valve controlling the admission of steam to the radiator, return connections, a valve-stem, a cam surrounding the valve-stem, a cam-follower secured to the stem, the said cam being so proportioned that a fraction of a full rotation of the follower suffices to open the valve to the point where it admits the normal maximum quantity of steam condensable by the radiator, and an index-scale for the cam-follower which marks the point of said normal opening; the full movement of the valve being limited to one revolution of the cam-follower.

4. In a steam-heating system of the class indicated, the combination of a radiator, a steam-valve controlling the admission of steam to the radiator, return connections, a valve-stem, a cam surrounding the valve-stem, a cam-follower secured to the stem, the said cam being so proportioned that a fraction of a full rotation of the follower suffices to open the valve to the point where it admits the normal maximum quantity of steam condensable by the radiator, and an index-scale for the cam-follower which marks the point of said normal opening; the full movement of the valve being limited to one revolution of the cam-follower, and the portion of the cam beyond the point of normal maximum condensable steam delivery being of greater pitch than the initial-opening portion.

705,982. MAIL DELIVERY AND COLLECTION SYSTEM. FRANKLIN S. VOSBE, Keokuk, Iowa. Filed Sept. 6, 1901. Serial No. 74,570. (No model.)

Claim.—1. In a mail delivery and collection system, the combination of an elevated car having an opening in its bottom, a closure arranged to swing across the opening, a pinion to swing the closure, a gearing to reciprocate the pinion, and a chute communicating with the said opening in the car, substantially as described.

2. In a mail delivery and collection system, the combination of an elevated car provided with an opening in its bottom, a closure arranged to swing across the opening, means to swing the closure, a chute communicating with the said opening in the car, a door adjacent to the top of the chute, and mechanism connected to the door and having an element extending in the path of the car whereby the door is opened.

3. In a mail delivery and collection system, the combination with an electrically-propelled elevated car, of a stationary collection-box supported in an elevated position to discharge its contents into the car, a collection-box adapted to be raised, a hinged cover for the stationary box formed with a projection, and a device carried by the movable box adapted to strike said projection and open both boxes simultaneously.

4. In a mail delivery and collection system, an electrically-propelled elevated car having a discharge-opening in its bottom, mechanism therein for supporting and discharging mail, comprising an endless carrier, removable partitions in the carrier, a swinging door to open and close the opening in the car, a chute with which the opening communicates, a door to close the chute, and means to automatically open and close the door.

5. In a mail delivery and collection system, an electrically-propelled elevated car, and mechanism therein for supporting and discharging mail comprising an endless carrier provided with removable partitions in combination with a receiving-chute, and means for automatically opening and closing said chute.

6. In a mail delivery and collection system, the combination with an electrically-propelled elevated car, of an endless carrier therein for supporting mail-matter removable partitions on said carrier, a hinged door, mechanism for opening and closing said door, a receiving-chute, and means for automatically opening and closing said chute.

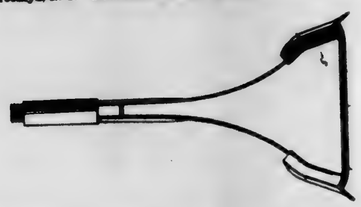
7. In a mail delivery and collection system, the combination with an electrically-propelled elevated car, of an endless carrier supported therein, removable partitions on said carrier for separating and supporting mail-matter, gearing for rotating said carrier, a hinged door for the car, and mechanism connected with said gearing for opening and closing said door.

8. In a mail delivery and collection system, the combination with an electrically-propelled elevated car, of an endless carrier supported therein, comprising parallel chains, cross-bars connecting said chains, a covering for said cross-bars and a plurality of pairs of fingers projecting from

said chains; removable partitions held by said fingers and means for revolving the endless carrier.

9. In a mail delivery and collection system, the combination with an electrically-propelled car, of a collection-box provided with a hinged door, a diagonally-disposed pivoted plate within the box and connected to the door by links, and means for tilting said plate upon its pivot to open the door, consisting of a longitudinally-movable rod and toggle-levers supporting said rod between the front wall of the box and said plate.

705,988. BOTTLE-WASHING BRUSH. CARL K. VOLCKENING, Brooklyn, N. Y. Filed Mar. 13, 1902. Serial No. 98,004. (No model.)



Claim.—1. A bottle-washing brush comprising expanding fingers the end of each finger being provided with an opening, and a rubber-brush material having socket members to engage over said ends of the fingers, portions of the socket members engaging in said openings, substantially as specified.

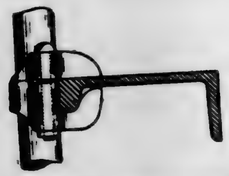
2. In a bottle-washing brush, spring-fingers, each finger having its end turned over upon the main portion, the said turned-over end having a rearwardly-opening slot or channel, and a rubber brush having socket members for engaging over said ends, substantially as specified.

3. A bottle-washing brush comprising spring-fingers, a rubber-brush material having socket members for engaging over the ends of the fingers, and a cross-strip connecting the socket members, the said cross-strip at its ends being curved rearward toward the ends of the fingers, substantially as specified.

4. A bottle-washing brush comprising socket members, spring-fingers for engaging in said socket members, a cross-strip connecting the socket members, longitudinal ribs on said cross-strip, and a transverse central rib on said cross-strip, substantially as specified.

5. A bottle-washing brush comprising spring-fingers, a rubber-brush material having socket members for engaging on said fingers and having a cross-strip, longitudinal ribs on said cross-strip, crossed ribs on the cross-strip, and a transverse central rib, substantially as specified.

705,984. CONDUIT-CLAMP. FRANK O. WELLINGTON, Braintree, Mass., assignor to Fore River Ship and Engine Company, Quincy, Mass., a Corporation of New Jersey. Filed Oct. 15, 1901. Serial No. 78,705. (No model.)

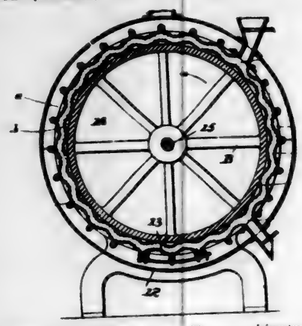


Claim.—1. A conduit-clamp comprising a substantially U-shaped body having its arms provided with notches or recesses facing in the same direction to fit over a flange of a beam, and means carried by said body for engaging the opposite side of the beam-flange, whereby said recessed arms will be confined in clamped position without exerting pressure on the conduit.

2. A conduit-clamp comprising a substantially U-shaped body having its arms adapted to engage one side of a beam, stud jaws movable toward the sides of the arms of said body, and means for moving both jaws in the same direction to engage the opposite side of a beam from that engaged by the arms of the U-shaped body.

3. A conduit clip or clamp consisting of a U-shaped body having an integral jaw at each end and cotiperating jaws attached to said body for securing said body to a projecting plate, the jaws being so arranged relatively to the U-shaped body as to confine a conduit between the U-shaped body and the plate without exerting pressure on the conduit, substantially as described.

705,985. MACHINE FOR CLEANING RICE &c. ROSIA W. WILSON, Baltimore, Md., assignor, by mesne assignments, to Southern Rice Polishing Machine Company, Baltimore, Md., a Corporation of Maryland. Filed Dec. 19, 1900. Renewed Dec. 19, 1901. Serial No. 86,584. (No model.)



Claim.—1. A grain-cleaning machine comprising two members, one of which is rotatable, each of its members having an annular sinuous surface opposed to the like surface of the other member, the high or contiguous portions *a*, *b* of said surfaces being close to each other in passing to temporarily form pockets and being only separated sufficiently to prevent grinding the grain between them, walls for confining the grain in the space between said surfaces whereby it is caused to travel circumferentially, and inlet and discharge openings to said space.

2. A grain-cleaning machine comprising two members, one of which is rotatable, each of its members having an annular roughened sinuous surface opposed to the like surface of the other member, the high or contiguous portions *a*, *b* of said surfaces being close to each other in passing to temporarily form pockets and being only separated sufficiently to prevent grinding the grain between them, walls for confining the grain in the space between said surfaces whereby it is caused to travel circumferentially, and inlet and discharge openings to said space.

3. A grain-cleaning machine comprising two members, one of which is rotatable, each of its members having an annular sinuous screen opposed to the like screen of the other member, the high or contiguous portions *a*, *b* of said screens being close to each other in passing to temporarily form pockets and being only separated sufficiently to prevent grinding the grain between them, walls for confining the grain in the space between said surfaces whereby it is caused to travel circumferentially, and inlet and discharge openings to said space.

705,986. REIN-GUARD. JOHN T. WEST, Bowling Green, Ky. Filed July 10, 1901. Serial No. 67,710. (No model.)

Claim.—1. The combination with a divided crupper-strap and a crupper, of a rein-guide frame confined at its front end and having at its rear end a drop member which depends below the longitudinal plane of said frame, and a transversely-arranged confining-loop engaging with the members of said crupper in rear of the division in the crupper-strap, and forming a support for said rein-guide frame.

2. The combination with a divided crupper-strap and a crupper, of a rein-guide frame having the side bars extending forwardly from a rear drop member, and a confining-loop engaging with the side members of the crupper in rear of the division in the crupper-strap, and also engaging with the side bars of said frame, said side bars being confined against displacement relative to the parts by the side members of the crupper and by the end portions of said loop.

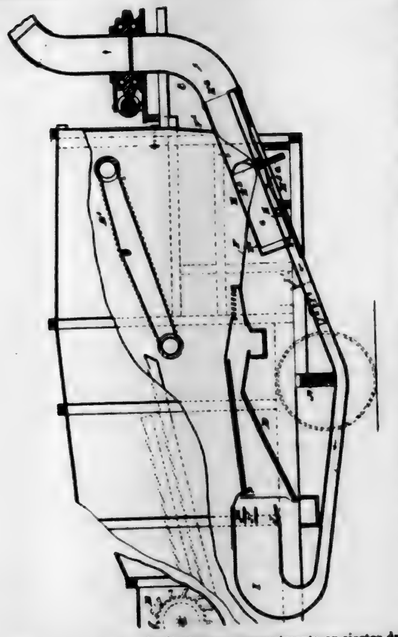
3. The combination with a divided crupper-strap and a crupper, of a rein-guide frame having side bars extending forwardly from a rear member, and a confining-loop slidably fitted to the side members of the crupper and to the side bars of said frame, said loop engaging with the crupper in rear of the division in the crupper-strap, and the side bars of the frame being held against displacement by the end portions of the loop and the side members of the crupper.

4. The combination with a crupper and a divided crupper-strap, of two loops disposed one in rear of the other and both engaging with the members of the crupper in rear of the division in the crupper-strap, and a rein-guide frame having side bars confined by and engaged with both of said loops, said side bars being provided with projections which engage the front loop and restrain said frame from rearward endwise movement.

5. The combination with a divided crupper-strap and a crupper, of a confining-loop engaging with said crupper-strap, a rein-guide frame having its side bars fitted between the members of the crupper-strap and the ends of the loop, and provided with projections arranged to fit against the loop and to restrain the frame from rearward endwise movement, and means engaging with the crupper and with the frame at a point intermediate of the length of the latter to support said frame in rear of said loop.

6. The combination with a crupper, of a confining-loop having its end portions doubled upon itself and forming keepers arranged to loosely receive the said members of the crupper, and a rein-guide frame having side bars extending forwardly from a rear member and fitted loosely within said confining-loop, said side bars being held from displacement by engaging with the members of the crupper and with the end portions of the loop.

705,987. THRESHING OR SEPARATING MACHINE. GEORGE R. WILSON, Stillwater, Minn. Filed Sept. 13, 1900. Serial No. 730,269. (No model.)



Claim.—1. A stacker-fan having two compartments, an ejector-duct leading from one of said compartments, means for delivering material to be stacked to the ejecting compartment of the fan, and means for delivering a blast from the other compartment of the fan against said material before it enters the fan to force the same toward and into the fan.

2. A stacker-fan having two compartments, an ejector-duct leading from one of said compartments, means for delivering material to be stacked to the ejecting compartment of the fan, said fan being arranged in an approximate horizontal position, with one of said compartments above the other, and means for delivering a blast from the lower compartment of the fan against said material before it enters the fan to force the same into and toward the fan.

3. A stacker-fan having two compartments, an ejector-duct leading from one of said compartments, means for delivering the material to be stacked to the ejecting compartment, and means for delivering a blast from the other compartments of the fan against said material before it enters the material to force the same toward and into the fan, said fan having a moving straw-supporting partition between the material-receiving eye, and said other compartment.

4. In a threshing and stacking mechanism, the combination of a stacker-fan having means for producing a suction air-current and a separate positive blast, an ejector-duct, into which said suction-current is delivered, means for delivering the material to be stacked to the suction portion of the fan, and devices for directing the said positive blast from said fan into the suction portion of the fan.

5. In a combined threshing and straw-stacking mechanism, the combination of means for supplying threshed material, a straw-separating device, a fan having two compartments to one of which the separated straw is delivered, an ejector-duct leading from the straw-receiving compartment of the fan, air-blast-conducting passages leading from the other compartment of the fan and back to the eye of the straw-receiving compartment, and chaff-separating means located in said passages in the path of said blast.

6. In a combined threshing and straw-stacking mechanism, the combination of the following elements, namely: threshing devices, a straw-separating mechanism, grain and chaff separating means, a final ejecting-duct for chaff and straw, a fan-casing situated relatively between the final ejector-duct and the grain and chaff separating means, an inlet to the fan-casing for chaff and straw, a chamber communicating with said inlet and adapted to receive the chaff from the grain and chaff separating means and the straw and deliver both to said inlet, a rotary fan in said casing adapted to positively engage both the chaff and the straw and drive them through said ejector-duct and supply a blast of air to said duct and means for taking from said fan-casing a blast of air forward to the front side of the grain and chaff separating means to drive the chaff backward therefrom into the said chaff and straw chamber, substantially as set forth.

7. In a threshing-machine, the combination of the straw-separator, the grain and chaff separating means, the final straw-ejecting duct, a chamber or duct receiving the chaff immediately after it leaves the grain and chaff separating means, a fan situated relatively between the grain and chaff separating means and the final straw-ejector duct, a casing for the fan divided by a partition, a straw-conduit delivering straw from the straw-separator to one portion of the fan, the fan being adapted to positively engage with the straw as the latter passes through said casing and drive it through said final ejector-duct, and a duct leading from the other portion of the fan and extending relatively forward to the grain and chaff separating means and delivering thereto a positive blast of air adapted to carry the chaff therefrom to the said chaff chamber or duct, substantially as set forth.

8. In a threshing-machine, the combination of a threshing mechanism, a final straw-ejecting duct, a straw-separating mechanism receiving the straw from the thresher, a fan at the rear of the straw-separating mechanism arranged to receive and positively engage with the threshed straw and force the same through the ejector-duct, a grain and chaff separating means situated relatively forward of said fan, and an air-duct extending forward from said fan to the grain and chaff separating means whereby a positive blast of air is delivered to the grain and chaff separating means adapted to carry the chaff backward toward the straw-duct.

9. In a threshing-machine, the combination of a threshing-cylinder rotating on an axis relatively forward in the machine, a straw-separating mechanism at the rear of the threshing-cylinder, a fan at the rear of the straw-separater on an axis remote from that of the threshing-cylinder, a straw chamber or duct delivering the straw to said fan, the fan being adapted to positively engage with the straw and force it through the ejector-duct, a grain and chaff separating means relatively forward of said fan, an air-conduit leading from said fan to the forward part of the grain and chaff separating means and delivering a blast thereto in a rearward direction, and means for preventing the entrance of straw into the said air-conduit, substantially as set forth.

10. In a threshing-machine, the combination of a threshing mechanism, a straw-chamber, a final ejector-duct, a stacker-fan between the threshing mechanism and the ejector-duct, a casing for said fan having an upper compartment and a lower compartment cut off from the ejector-duct, the upper compartment having an upturned straw-receiving eye through which the straw enters to the fan and from which it passes to the ejector-duct, and the lower compartment having an independent air-receiving eye, a grain and chaff separating means, and an air-conduit leading from the lower fan-compartment to the grain and chaff separating means to deliver a positive air-blast thereto, substantially as set forth.

11. In a threshing-machine, the combination of the straw-separator, the grain and chaff separating means, a fan-casing having an upwardly-turned eye and divided into two compartments, a chamber or duct which receives chaff from the grain and chaff separating means and straw from the separator, and guides both to the said eye, a final ejector-duct communicating with the upper compartment, a duct leading from the lower compartment to the grain and chaff separating means and a fan in said casing adapted to positively engage with the straw and chaff and eject them from said casing and also adapted to drive a positive blast of air

through the grain and chaff separating means to carry the chaff to the ejecting-compartment, substantially as set forth.

12. The combination of the straw-separating mechanism, the grain and chaff separating means, the final straw-ejecting duct, the fan-casing having a straw-receiving eye in the path of the straw and an interior rotary partition below said straw-receiving eye dividing it into two compartments, fan-blades on both sides of the partition, one of said compartments communicating with the final straw-ejector duct, and an air-blast duct leading from the other of said compartments to the grain and chaff separating means, substantially as set forth.

13. In a threshing-machine, the combination of threshing devices a straw-separating mechanism for separating the straw from the grain, grain and chaff separating means, a fan-casing having an eye adapted to receive the threshed straw, a straw ejecting or stacking duct, a fan in said casing, a diaphragm separating the casing into two parts, with one of which said straw-receiving eye communicates, and an air-supply eye for the other part of said fan, and a blast-duct leading from the latter part of said fan to said grain and chaff separating means, substantially as set forth.

14. In a threshing-machine, the combination of threshing devices, a straw-separating mechanism for taking the straw from the grain, grain and chaff separating means, a fan-casing having an upturned eye to receive the threshed straw, a straw ejecting or stacking duct, a fan in said casing having a diaphragm moving with the fan and separating the casing into two parts, with one of which parts said straw-receiving eye communicates, an air-supplying means for the under part of said fan, and a blast-duct leading from the latter part of said fan forward at the lower part of the machine to said grain and chaff separating means, substantially as set forth.

15. In a threshing-machine, the combination of threshing devices, a straw-separating mechanism for taking the straw from the grain, grain and chaff separating means, a fan-casing having an eye adapted to receive the threshed straw, a straw ejecting or stacking duct, a fan in said casing having a diaphragm moving with the fan and separating the casing into two parts, with one of which parts said straw-receiving eye communicates, an air-supply means for the other part of said fan and a blast-duct leading from the latter part of said fan to said grain and chaff separating means, the latter being arranged to deliver chaff to said straw-receiving-eye, substantially as set forth.

705,988. TOBACCO-PIPE. HENRY M. WILLIS, East Williston, N. Y. Filed Apr. 5, 1901. Renewed Dec. 30, 1901. Serial No. 87,623. (No model.)

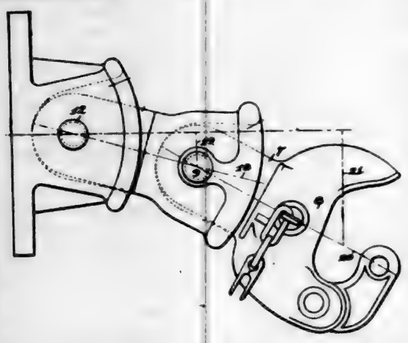
Claim.—1. In a tobacco-pipe, the combination with a bowl which has a cylindric bore axially coincident with the tube or passage of the pipe-stem, and a cavity in its outer surface which connects with said bore, of a plug which is arranged to turn in said bore, an arm which is provided to the outer end of said plug and arranged to lie in said cavity with its outer surface flush or substantially so with the contiguous external surface of the bowl, and a semicylindric scoop provided to the inner end of the plug, placed in the passage of the pipe-stem and arranged to scrape the surface of said passage when turned by an axial movement of the plug, substantially as herein described.

2. In a tobacco-pipe, the combination with a bowl which has a cylindric bore axially coincident with the tube or passage of the pipe-stem, and a cavity in its outer surface which connects with said bore, of a cylindric plug which is arranged to turn in said bore, an arm which is provided to the outer end of said plug and arranged to lie in said cavity with its outer surface flush with the adjacent outer surface of the bowl, and with a space between the edge of the arm and the edge of the cavity for the insertion of an instrumentality for starting the plug from the bore, and a semicylindric scoop provided to the inner end of the plug and placed in the passage of the pipe-stem to scrape the same by a turning movement of the scoop, substantially as herein described.

705,989. INTERMEDIATE COUPLING. WILLIAM C. WILSON, St. Louis, Mo. Filed May 26, 1902. Serial No. 109,099. (No model.)

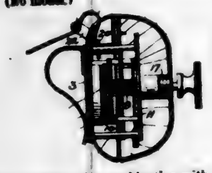
Claim.—1. The combination with a socket and a coupler-head adapted to be pivotally mounted in the socket; of an intermediate coupler adapted to be pivotally mounted in the said socket upon the removal of the coupler-head therefrom, and adapted to pivotally mount the coupler-head; substantially as specified.

2. The combination, with the usual socket and coupler-head, of an intermediate coupler adapted to be inserted between the coupler-head and the socket to increase the lateral motion of the coupler-head; substantially as specified.



3. The combination with the usual socket and coupler-head, of an intermediate coupler adapted to be inserted between the socket and the coupler-head to increase the lateral motion of the coupler-head; said intermediate coupler being offset so as to change the height of the coupler-head by reversing the intermediate coupler; substantially as specified.

705,990. ALARM FOR REFRIGERATOR-PANS. PHILIP VON and LOUIS LAPENE, North Adams, Mass. Filed May 27, 1902. Serial No. 109,196. (No model.)



Claim.—1. In an alarm, the combination with a gong, of a spring-motor, an escapement arranged to control said motor, a lever bearing a hammer located to strike said bell, a slidingly-mounted pinion mounted to be driven by said motor and bearing a pin located to engage said lever to hold said escapement inoperative, a lever bearing a float and arranged to operate said pinion to disengage said pin from said first-mentioned lever, substantially as described.

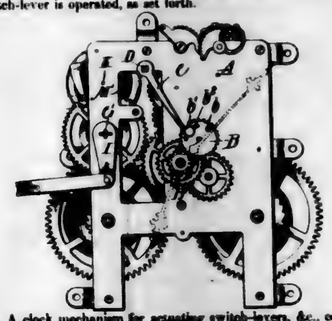
2. In an alarm, the combination with a bell, of a spring-motor, a lever bearing an escapement arranged to control said motor and carrying a hammer located to strike said bell, a slidingly-mounted pinion arranged to be driven by said motor, a lug and a shorter pin carried by said pinion and located to engage said lever to hold said motor inoperative, a lever engaging said pinion, and a float positioned to be operated to release said motor, substantially as described.

3. In an alarm, the combination with a spring-motor, means arranged to control said motor, a lever arranged to control said means, a slidingly-mounted pinion bearing a plurality of pins of graduated length located to engage said lever, means controlled by a float and arranged to operate said pinion to disengage said pins, substantially as described.

4. In an alarm, the combination with a bell, of a spring-motor, a lever bearing a hammer and an escapement arranged to control said motor, a slidingly-mounted pinion arranged to be driven by said motor, two pins of different length carried by said pinion and located to engage said lever, a lever one arm of which is connected to said pinion, and a float mounted on said last-mentioned lever and arranged to operate it to release said motor, substantially as described.

705,991. TIME-SWITCH MECHANISM. GEORGE ZAEPFEL, Croghan, N. Y., assignor of one-half to George W. Henderson, Croghan N. Y. Filed Oct. 24, 1901. Serial No. 79,846. (No model.)

Claim.—1. A clock mechanism for actuating electrical switches, &c., comprising a series of spring-actuated gear-wheels, a crank actuated by said wheels, a switch-lever pivoted to said arm, a setting-wheel in mesh with a clock-work, pins mounted on said setting-wheel, a trip-arm disposed in the path of said pins, a lock-lever normally holding said gear mechanism from rotation, and actuated by the trip-lever, a momentum-wheel, turning with the spring-actuated wheel in one direction, and designed to turn idly after the switch-lever is operated, as set forth.



2. A clock mechanism for actuating switch-levers, &c., comprising a spring-actuated gear, a crank operated thereby, a lever pivoted to said crank, a setting gear-wheel and clock mechanism for operating same, pins on said wheel, a trip-arm disposed in the path of said pins, a momentum-wheel actuated as the crank is given a one-half rotation, and allowed to turn idly after the crank has been arrested, and means, actuated by said trip-arm, to allow the gear mechanism to operate, as set forth.

3. In combination with the spring-actuated gear mechanism, a stop-wheel actuated thereby, a crank actuated by the gear mechanism, pins on the face of said stop-wheel, a shaft geared to said stop-wheel, a momentum-wheel turning idly in one direction on said shaft after the switch is thrown, a setting-wheel and clock-work geared thereto, a trip-lever and pins on the setting-wheel for actuating said lever, and means, operated by the trip-lever, for allowing the stop-wheel to rotate and for arresting same, as set forth.

4. In combination with a spring-actuated gear, a stop-wheel in mesh therewith, pins on said wheel, a setting-wheel and clock mechanism for actuating same, pins on said setting-wheel, a trip-lever, and rock-shaft to which it is fastened, said lever being disposed in the path of said pins on the setting-wheel, a lock-lever secured at one end to said rock-shaft, its other end disposed in the path of the pins on said stop-wheel, a shaft geared to the stop-wheel, a ratchet secured thereto, a momentum-wheel, a pawl carried by the latter and having engagement with said ratchet, said momentum-wheel having a free rotary movement in one direction independent of the ratchet, and allowed to stop gradually after being rotated by the pawl and ratchet, and after the stop-wheel has ceased to rotate, as set forth.

5. In combination with the spring-actuated gear, the stop-wheel, the pins thereon, the momentum-wheel and shaft carrying same, the ratchet on said shaft, and pawl carried by said wheel and engaging said ratchet, the setting-wheel, and clock-work mechanism for actuating same, the trip-arm and shaft to which it is secured, a lock-lever fastened to said trip-arm-carrying shaft, and engaging the pins of the stop-wheel, a lug on the shaft to which the lock-lever is fastened, and an arm on the momentum-wheel shaft adapted to contact with said lug which forms a stop to prevent the rotation of the stop-wheel until the pin on the graduated wheel has passed by the free end of said trip-arm, as set forth.

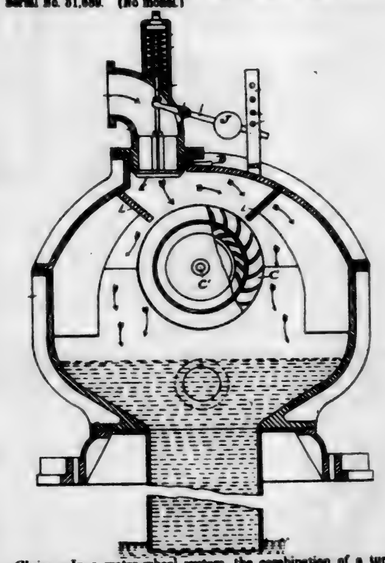
6. In combination with the spring-actuated gear mechanism, the stop-wheel, and shaft on which it is mounted, a crank on said shaft, and switch-lever pivoted to said crank, pins on the face of the stop-wheel, a shaft geared to said stop-wheel, a momentum-wheel on said shaft, a setting-wheel, and clock work mechanism geared thereto, said setting-wheel having an elongated aperture therein, an adjustable pin held in said aperture, a fixed pin on the face of the setting-wheel, a rock-shaft, a trip-arm secured thereto, and disposed in the path of said adjustable and fixed pins, a lock-lever secured to the rock-shaft and engaging the pins on the stop-wheel, a stop on said rock-shaft, and an arm, on the momentum-wheel shaft, which is designed to contact with said stop, as set forth.

705,992. SASH-WEIGHT. JOHN D. ASHLEY, Everett, Mass., assignor, by mesne assignments, to Allston Foundry Company, a Corporation of Maine. Filed June 19, 1901. Serial No. 65,166. (No model.)

Claim.—1. A sash-weight, having a central perforation in one end through which the suspending cord or chain passes, a recess in the top of which the nut or ring on the end of the cord or chain seats itself, and into the center of which said perforation opens, said recess extending centrally lengthwise the weight, and having its upper portion laterally flared or enlarged and provided with a dome-like top with self-centering walls, and an opening leading into the lower part of the recess, said opening being narrower than the widest part of said recess.

2. A sash-weight, having a central perforation in one and through which the suspending cord or chain passes, a recess in the top of which the knot or ring on the end of the cord or chain seats itself, and into the center of which said perforation opens, said recess extending centrally lengthwise the weight, and having its upper portion laterally flared or enlarged and provided with a dome-like upper end having self-centering walls converging toward the central perforation, and openings on opposite sides of the weight leading into the lower part of the recess, said recess having its greatest diameter above the top of the openings, and the latter being narrower than the widest part of the recess.

705,993. HORIZONTAL-WATER-WHEEL SYSTEM. ARTHUR GIESLER, Dayton, Ohio, assignor to the Stilwell-Bierce & Smith-Vaile Co., Dayton, Ohio, a Corporation of New Jersey. Filed Oct. 1, 1900. Serial No. 31,889. (No model.)



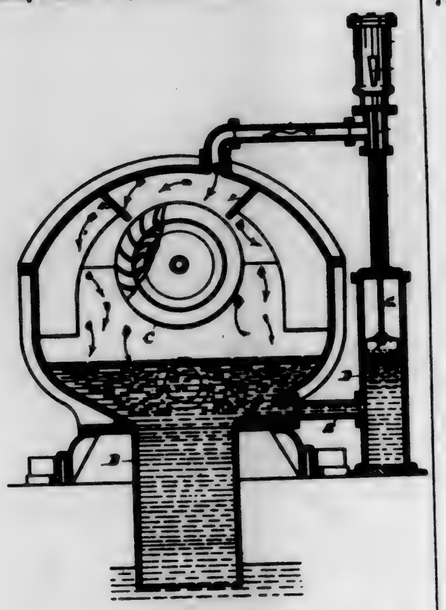
Claim.—In a water-wheel system, the combination of a turbine-casing, a draft-tube connecting said casing with the tail-water, a turbine in said casing, said turbine being of the impulse or Girard type, an air-valve opening into said casing above the surface of the water and upon the discharge side of the turbine, and yielding means to resist the opening of said valve by the atmosphere, whereby the height of the tail-water may be maintained approximately at a constant level for the purpose set forth.

705,994. TURBINE-WATER-WHEEL SYSTEM. ARTHUR GIESLER, Dayton, Ohio, assignor to the Stilwell-Bierce & Smith-Vaile Co., Dayton, Ohio, a Corporation of New Jersey. Filed Sept. 27, 1900. Serial No. 31,243. (No model.)

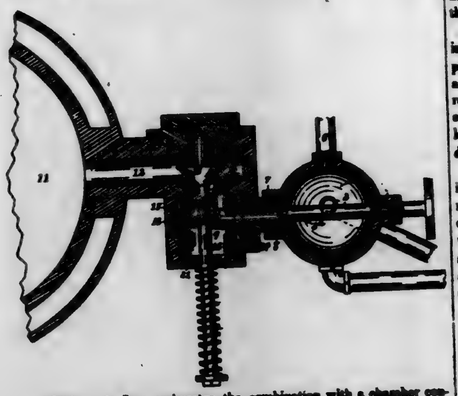
Claim.—1. In a horizontal-water-wheel system, the combination of a turbine-casing, a horizontal turbine wheel mounted in said casing, said turbine wheel being of the impulse or Girard type, a draft-tube connecting said casing with the tail-water, an auxiliary water-chamber, a communication between the draft-tube or wheel-casing and said auxiliary water-chamber, a float within said auxiliary water-chamber, an air-valve controlled by said float, and a communication between said air-valve and the turbine-casing whereby air is discharged into said turbine-casing above the surface of the water, substantially as and for the purposes specified.

2. In a horizontal-water-wheel system, the combination of a turbine-casing, a horizontal turbine wheel mounted in said casing, said turbine being of the impulse or Girard type, a draft-tube connecting said casing with the tail-water, an auxiliary water-chamber, a passage between the draft-tube or wheel-casing and said auxiliary water-chamber, a float

within said auxiliary water-chamber, an air-valve carried by said float, and a communication between said air-valve and said turbine-casing whereby air is discharged to said turbine-casing above the turbine wheel, substantially as and for the purposes specified.



705,995. CARBURETER FOR EXPLOSIVE-ENGINES. GEORGE A. GRAVES, Joplin, Mo., assignor of two-thirds to Thomas W. Cunningham and Alfred Reynolds, Joplin, Mo. Filed Oct. 15, 1901. Serial No. 78,698. (No model.)



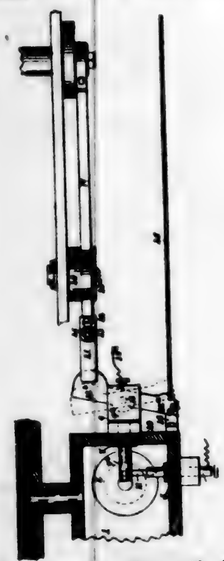
Claim.—1. In a carbureter, the combination with a chamber constructed to be connected to an engine and having air and gasolene connections, of a gasolene-cup mounted in said chamber, a valve bearing a vaporizer located to normally dip into said cup aft to be lifted out of said cup when said valve is mounted, substantially as described.

2. In a carbureter, the combination with a chamber constructed to be connected to an engine and having air and gasolene connections, an annular cup located in said chamber, a valve bearing a vaporizer dipping into said cup when said valve is seated and being withdrawn therefrom when said valve is mounted, substantially as described.

3. In a carbureter, a vaporizer comprising an annular member mounted on a valve-stem and bearing a serrated rim thereon, substantially as described.

4. In a carbureter, a cup, and a vaporizer bearing a serrated rim constructed to fit into said cup, substantially as described.

705,996. SPARKER FOR EXPLOSIVE-ENGINES. GEORGE A. GRAVES, Joplin, Mo., assignor of two-thirds to Alfred Reynolds and Thomas W. Cunningham, Joplin, Mo. Filed Oct. 15, 1901. Serial No. 78,699. (No model.)



Claim.—1. In a sparker, the combination with a fixed electrode, of a shaft bearing an electrode located to be brought into engagement with said fixed electrode, a lever pivoted on said shaft, a pair of springs connected to said lever and each mounted to exert a component of force on the lever at right angles to the force of the other, and means for intermittently engaging and releasing said lever to make and break a circuit through said electrode to make a spark, substantially as described.

2. In a sparker, the combination with an electrode, of a shaft bearing an electrode located to engage said first-mentioned electrode, a lever pivoted on said shaft, a first spring having an arm slidingly mounted in an aperture in said lever, a second spring connected to said lever and arranged to exert a component of force at right angles to the force exerted by said first spring, and means for intermittently engaging and releasing said lever to make and break a circuit through said electrode, substantially as described.

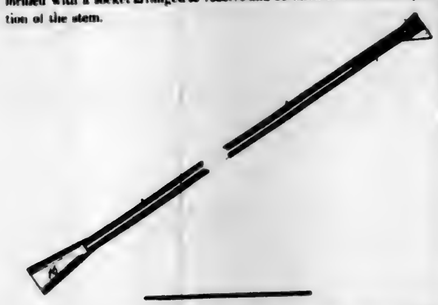
3. In a sparker, the combination with an electrode, of a shaft having an electrode located to be brought into engagement with said first-mentioned electrode by rotating said shaft, a lever mounted on a pivot extending at right angles to said shaft, two springs connected to said lever and arranged to exert pulls on said lever at right angles to each other, and a pitman bearing a spring-actuated yielding arm secured at one end and located to intermittently engage said lever as said pitman is operated, substantially as described.

705,997. COMBINATION MINER'S TOOL. MARTIN HARRISON, Ottumwa, Iowa, assignor of one-half to Lester G. Hartsoog, Ottumwa, Iowa. Filed May 21, 1901. Serial No. 61,961. (No model.)

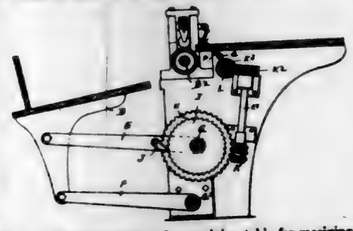
Claim.—1. A miner's combination-tool comprising a tubular stem, a tubular funnel-shaped cleaner on one end of said stem and a tamping-head on the opposite end of said stem, said tamping-head mounted eccentrically on said stem and notched radially for straddling a miner's needle when in use.

2. A miner's combination-tool, comprising a stem, a tool member on one end of said stem, a tamping-head on the opposite end of said stem, said tamping-head mounted eccentrically on said stem and bored in alinement with the bore of the stem for the reception of a miner's needle, said tamping-head being notched for straddling the miner's needle when in use.

3. A combination miner's tool, comprising a tubular stem, a tool member on one end of said stem, the opposite end of said stem being reduced in cross-section, and a tamping-head mounted eccentrically on and formed with a socket arranged to receive and be fixed to the reduced portion of the stem.



705,998. ADJUSTABLE RECEIVING-TABLE FOR SCORING-MACHINES. CLARENCE W. HOBBS, Worcester, Mass. Filed Aug. 5, 1898. Serial No. 687,753. (No model.)



Claim.—1. The combination of a receiving-table for receiving the scored cardboard, mechanism for lowering the table and mechanism for controlling the action of said table-lowering mechanism comprising a member arranged in the path of the cardboard, substantially as described.

2. The combination with a receiving-table, for receiving paper or cardboard from a scoring-machine, mechanism for lowering said receiving-table as the cardboard is delivered thereon, a clutching mechanism by which said table-lowering mechanism is operatively connected with the driving power and a clutch-controlling mechanism arranged in the path of the cardboard as it passes through the machine and arranged to be actuated thereby, whereby said table is lowered by the passage of a sheet of cardboard through the machine, substantially as described.

3. In a scoring-machine, the combination with mechanism for scoring cardboard, of a receiving-table, a framework supporting said table and pivotally connected with the frame of the scoring mechanism, means controlled by the cardboard for rocking said table, whereby said table is lowered, substantially as described.

4. The combination of a receiving-table, a framework on which said table is mounted, parallel links by which said table is pivotally connected with the fixed framework, and means for rocking one of said links to lower the table, substantially as described.

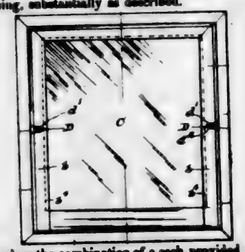
5. The combination with a receiving-table for scoring-machines, of mechanism for lowering said table during the delivery of cardboard thereon, a clutching mechanism by which said table-lowering mechanism is operatively connected with the driving power, a clutch controlling mechanism comprising a tripping member operatively connected with the clutching mechanism and placed in the path of a sheet of cardboard as it passes through the machine, substantially as described.

6. The combination of a rocking shaft, links pivoted on said shaft, a receiving-table supported on said links, a ratchet-wheel attached to said shaft, a pawl pivoted on one of said links and engaging said ratchet-wheel, and mechanism by which said shaft is rotated and said receiving-table lowered, substantially as described.

7. The combination of a rocking shaft, arms pivoted on said shaft, a receiving-table supported on said arms, a ratchet-wheel attached to said shaft, a pawl pivoted on one of said arms and engaging said ratchet-wheel, mechanism for rotating said shaft, a clutching mechanism by which said rotating mechanism is operatively connected with the driving power and a clutch-controlling mechanism arranged in the path of the cardboard as it passes through the machine, substantially as described.

705,999. WINDOW. JOHN HOSSFELD, Chicago, Ill. Filed Apr. 3, 1902. Serial No. 101,266. (No model.)

Claim.—1. A window-sash having the top rail and side members provided with flanges adapted to form channels for inserting and retaining the pane, said channels being substantially twice the thickness of the pane, and a bottom rail sufficiently narrower than the other members to allow the glass to be inserted in said channels, and provided with a shoulder corresponding with shoulders on the other members so that the pane when inserted in said channels may be pressed against said shoulders for permanent fastening, substantially as described.



2. In a window the combination of a sash provided with stiles having curved outer edges and yielding closures adapted to engage said stiles.

3. In a pivot-window, the combination of a sash having the outer edges of the stiles thereof curved, and pivoted yielding closure-strips engaging said stiles.

4. In a window, the combination of a frame, a sash pivoted to said frame, and pivoted closure-strips yieldingly engaging said sash.

5. In a window, the combination of a frame, longitudinal channels in said frame, a sash, and closure-strips pivoted in said channels adapted to yieldingly engage said sash.

6. In a window, or equivalent device, the combination of a frame provided with channels, a sash having curved edges pivoted in said frame, longitudinal closure-strips pivoted in said channels, said strips being provided with curved faces to engage said sash and curved reversely-bent flange adapted to engage the walls of said channels, and means for holding said strips in yielding engagement with said sash.

7. A window-frame constructed of sheet metal, having the inner faces of the frame sides bent out at substantially right angles and reversely bent at a bevel to form channels therein and inner stay-plates at intervals along said faces substantially as herein described.

8. In combination a frame having longitudinal channels or grooves, a sash having stiles with curved edges pivoted in said frame in alinement with said channels or grooves, closure devices pivoted in said channels having curved faces engaging said stiles and curved flanges slidingly engaging the walls of said channels and springs adapted to press against said closure devices to urge them against the sash-stiles.

9. In combination with a pivot-window and its frame, a yielding closure-strip divided at a point opposite or near the pivot whereby only one portion of said strip is pressed back when the window is opened.

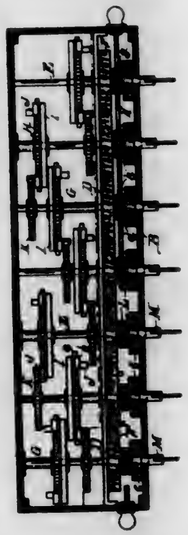
706,000. ADDING-MACHINE. JUDAH I. LEVIN, Detroit, Mich. Filed Nov. 18, 1901. Serial No. 82,636. (No model.)

Claim.—1. In an adding-machine, a series of fixed gear-wheels spaced at intervals apart, and a corresponding series of shafts journaled in axial line therewith carrying a like set of gear-wheels and the number-carrying wheels, a series of spring gear-teeth carried by said shafts in traveling contact with said fixed gears and adapted at intervals to mesh with the movable gears to impart a predetermined movement thereto, and a series of keys sleeved on said shafts having ratchet-and-pawl connection with said shafts to impart movement thereto in either direction as desired.

2. In an adding-machine, a series of fixed gear-wheels spaced at intervals apart, and a corresponding series of shafts journaled in axial line therewith, carrying a like set of gear-wheels and the number-carrying wheels, of a series of spring-teeth carried by said shafts in mesh with the fixed gears and adapted to be projected into mesh with the movable gears at intervals to impart movement thereto, and a series of keys sleeved on said shaft and having a ratchet-and-pawl connection therewith, said keys carrying numbers corresponding to those of the number-wheels but arranged in the inverse order.

3. In an adding-machine, a series of fixed gear-wheels spaced at intervals apart, and a corresponding series of shafts journaled in axial line therewith, carrying a corresponding series of gear-wheels and number-wheels, carrying a double set of numbers, from "0" to "9," of a pair of spring-teeth carried by each of said shafts, traveling in contact with the fixed gears and on opposite sides thereof, adapted at intervals to mesh with the next adjacent movable gear one tooth at a time, and a series of keys having ratchet-and-pawl connection with said shafts, said keys carrying numbers corresponding to those on the number-carrying wheels but arranged in the inverse order.

4. In an adding-machine, a series of fixed gear-wheels spaced at intervals apart and a corresponding series of shafts journaled in axial line therewith, carrying number-carrying wheels, and a corresponding series of gear-wheels, spring-teeth carried by said shafts in mesh with the fixed gears, and adapted to be projected at intervals into mesh with the movable gears, a series of ratchets carried by said shafts and a series of reversible pawls adapted to transmit motion to the ratchets through the medium of a key and a reversing-bar for tilting the pawls in either direction.



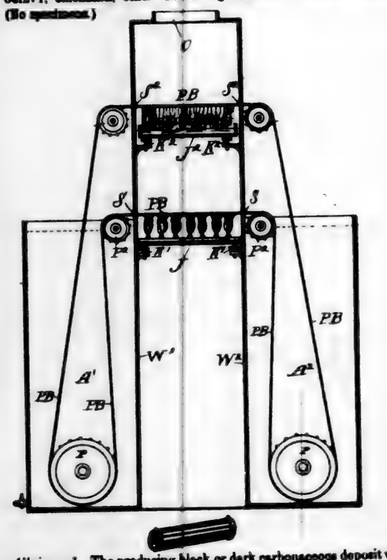
5. In an adding-machine, a series of fixed gear-wheels spaced at intervals apart, and a corresponding series of shafts formed with ratchets journaled in axial line therewith, carrying number-carrying wheels and a corresponding series of gear-wheels, spring-teeth carried by said shafts in mesh with the fixed gears and adapted to be projected at intervals into mesh with the movable gears, and a series of keys carrying numbers corresponding to those of the number-wheels but arranged in the inverse order, reversible pawls carried by said keys adapted to transmit motion to said ratchets in either direction and a reversing-bar for actuating the pawls.

6. In an adding-machine, a series of fixed gear-wheels and a corresponding series of shafts carrying a like series of movable gear-wheels and a series of number-carrying wheels, spring gear-teeth carried by said shafts meshing with the fixed gears and of a width greater than said gears and adapted at determined intervals to mesh with the next adjacent movable gear to the left to impart a proportionate movement thereto, a series of ratchet-drums carried by said shafts, formed with teeth corresponding in number to those of the gears, a series of keys sleeved on said shafts and bearing numbers corresponding to those of the number-wheels, but arranged in the inverse order, and a series of reversible pawls carried by said keys and adapted to turn said shaft in either direction.

7. In an adding-machine, a series of shafts and number-carrying wheels and means for transmitting motion from one shaft to the other in proportion to the numerical values which they represent, of a series of keys carrying numbers corresponding to those of the number-carrying wheels, but arranged in the inverse order, ratchet-and-pawl connections between said keys and shafts, means for reversing said pawl to turn the shaft in either direction and a stop to limit the return movement of the key.

8. In an adding-machine, a series of fixed gear-wheels and a corresponding series of shafts carrying a like series of movable gear-wheels, and a series of number-carrying wheels provided with two sets of numbers from "0" to "9," a pair of spring gear-teeth carried by each of said shafts meshing with the fixed gears on opposite sides thereof and adapted at intervals to move the next adjacent gear through the space of one tooth, said spring-teeth being of a width equal to that of both gears, a series of ratchet-drums formed on the shafts and having teeth equal in number to those of the gears, a series of keys formed with a lug or projection sleeved on said shafts and bearing numbers corresponding to those of the number-wheels but arranged in the inverse order, a series of tilting pawls carried by said keys and springs for holding said pawls in either direction, and a bar formed with pins for tilting said pawls to turn the shaft in either direction, said pins forming stops against which said lugs or projections are adapted to strike in the return movement of the key.

706,001. **PROCESS OF PRODUCING LAMPBLACK.** DAVID J. O'SULLY, Cincinnati, Ohio. Filed Aug. 15, 1897. Serial No. 648,167. (No specimens.)



Claim.—1. The producing black or dark carbonaceous deposit which consists in impinging a carbonaceous flame upon an aqueous surface, substantially as and for the purposes specified.

2. The process of producing black or dark carbonaceous deposits which consists in impinging a carbonaceous flame upon an aqueous surface while the said aqueous surface is in a state of motion, substantially as and for the purposes specified.

3. The process of producing black or dark carbonaceous deposits which consists in impinging a stationary carbonaceous flame upon an aqueous surface while the said aqueous surface is in a state of motion, substantially as and for the purposes specified.

4. The process of producing black or dark carbonaceous deposits, which consists in impinging a carbonaceous flame on an aqueous surface, and the presenting of an aqueous moving surface to receive and carry away the pigment deposited thereon, substantially as specified.

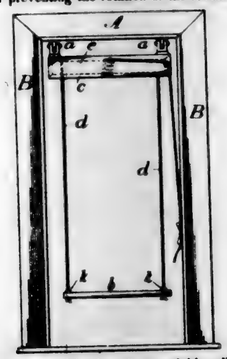
5. The process of producing black or dark carbonaceous deposits, which consists in impinging a carbonaceous flame on an aqueous surface, and then subjecting the resulting deposit of pigment to an aqueous bath or spray, substantially as specified.

6. The process of producing black or dark carbonaceous deposits, which consists in impinging a carbonaceous flame on an aqueous surface, and the adding of suitable soluble matter to the water required during the process so as to overcome the repellant nature of the carbonaceous deposit toward the water, substantially as and for the purposes specified.

REISSUES.

12,018. **SWING.** EDWARD LUBEK, New York, N. Y., assignor of two-thirds to Henry C. Babcock, Jr., and John P. Tupper, borough of Bronx, New York, N. Y. Filed Feb. 1, 1902. Serial No. 92,229. Original No. 670,287, dated Mar. 19, 1901.

Claim.—1. In a swing, the combination of a revolvable roller, a support for the roller containing journals for the same and adapted to be fastened to the lintel of a door, two flexible suspending means each secured to said roller and adapted to be wound thereon, a hoisting-cord secured to said roller and arranged so as to be wound thereon when the suspending means are unwound, a seat carried by the suspending means and adapted to be raised into proximity to the revolvable roller by the winding of the suspending means about the roller effected by tension upon and the unwinding of the hoisting-cord and lowered into operative position by the unwinding of said suspending means and consequent winding of the hoisting-cord around the revolvable roller, and fastening means for preventing the rotation of the revolvable roller.

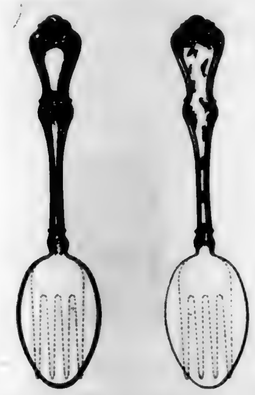


2. In a swing, the combination of a revolvable roller, a support for the roller containing journals for the same and adapted to be fastened to the lintel of a door, flexible suspending means secured to said roller and adapted to be wound thereon, a hoisting-cord secured to said roller and arranged so as to be wound thereon when the suspending means are unwound, a seat having a detachable back and carried by the suspending means and adapted to be raised into proximity to the revolvable roller by the winding of the suspending means about the roller effected by tension upon and the unwinding of the hoisting-cord and lowered into operative position by the unwinding of the suspending means and consequent winding of the hoisting-cord around the revolvable roller, and means for fastening the hoisting-cord.

3. In a swing, the combination with a case adapted to be fastened to the lintel of a door, means for so fastening such case, and a revolvable roller of uniform size through its whole length, and journaled in said case, of two ropes wound one way, one around each end of said roller, and extending without said case, a seat-board fastened on said ropes, a seat-back detachably fastened to said board and said ropes, a cord wound around the middle of said roller, in said case, in a direction opposite to said ropes, and extending without said case, and a cleat secured to the post of said door, upon which said cord is fastened to hold said swing-seat in any required position, substantially as set forth.

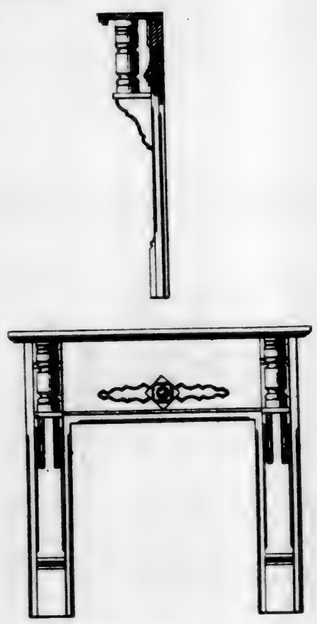
DESIGNS.

35,982. **HANDLE FOR SPOONS, FORKS, OR SIMILAR ARTICLES.** THEODORE REIDER, Providence, R. I., assignor to Roger Williams Silver Company, Incorporated, Providence, R. I. Filed Nov. 22, 1901. Serial No. 83,347. Term of patent 7 years.



Claim.—The ornamental design for the handle of a spoon, fork, or similar article, as herein shown and described.

35,983. **MANTEL.** WILLIAM H. WALKER and JAMES F. WALKER, Gate City, Ala. Filed May 17, 1902. Serial No. 107,879. Term of patent 7 years.



Claim.—The ornamental design for a mantel, as herein described and shown.

35,984. **AUTOCARETTE-BODY.** WILLIAM H. SCHNEIDER, Washington, D. C. Filed Apr. 11, 1902. Serial No. 102,485. Term of patent 14 years.

Claim.—The ornamental design for an autocarette-body, substantially as shown and described.

TRADE-MARKS

REGISTERED JULY 29, 1902.

38,664. CERTAIN NAMED YARNS AND THREAD. CALHOUN, ROBBINS & COMPANY, New York, N. Y. Filed Apr. 21, 1902.

The representation of a lion surrounded by tropical scenery, the whole inclosed in a circular band bearing the word "LION." Used since October, 1878.

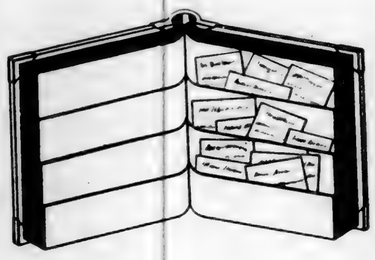
38,665. KNIT UNDERWEAR AND HOSIERY. ROBERT REIS & Co., New York, N. Y. Filed May 29, 1902.

A bust portrait of Benjamin Franklin within a circular border. Used since May 23, 1902.

38,666. WRAPPING, WAXED, AND TOILET PAPER. ALBANY PERFORATED WRAPPING PAPER CO., Albany, N. Y. Filed May 9, 1902.

The words "LOOK INTO THIS" and the representation of a box, with a hat beside the same and a man leaning over and looking into the box. Used since 1894.

38,667. SCRAP-BOOKS. THE PERFECT SCRAP BOOK CO., Albany, N. Y. Filed Apr. 4, 1902.



A picture or representation of an open scrap-book the leaves of which are provided with transverse pockets, in some of which are placed advertising-cards. Used since October 25, 1901.

38,668. DISK TALKING-MACHINES. WILBERT V. P. BRADLEY, Toledo, Ohio. Filed May 19, 1902.

The words "THE TALK-O-PHONE" and a surrounding scroll-like figure. Used since January 2, 1902.

38,669. CHECKER-BOARD GAMES. SALTA VERSAND VON AUGUST WASMUTH, Hamburg, Germany. Filed Feb. 5, 1901.

The picture of a person playing a checker-board game and thereunder the word "SALTA." Used since October, 1899.

38,670. GOLF-BALLS. H. HARTLEY CO., New York, N. Y., and Bridgeport, Conn. Filed Oct. 26, 1901.

The representation of a star surrounded by two concentric rings. Used since April 11, 1899.

38,671. CADDY-BAGS. THE H. HARTLEY COMPANY, Bridgeport, Conn., and New York, N. Y. Filed Apr. 5, 1902.

THISTLE

The word "THISTLE." Used since August 25, 1898.

38,672. VETERINARY REMEDY. EMMA M. KREISSER, Round Top, Tex. Filed June 7, 1902.

The representation of a standing bovine-calf. Used since December 20, 1901.

38,673. OINTMENT. CHARLES KIESEL, St. Louis, Mo. Filed Apr. 10, 1902.

ZEKO

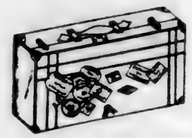
The word "ZEKO." Used since 1897.

38,674. LITTLE CIGARS AND CIGARETTES. CARL UPHAM, New York, N. Y. Filed May 14, 1902.

DRESS SUIT

The words "DRESS SUIT." Used since January 31, 1902.

38,675. LITTLE CIGARS AND CIGARETTES. CARL UPHAM, New York, N. Y. Filed May 14, 1902.



The pictorial representation of a dress-suit case, the said case having labels distributed carelessly over its front side. Used since January 31, 1902.

38,676. REMEDY FOR DANDRUFF AND A HAIR AND SCALP TONIC. SMITH T. DUSTIN, Chicago, Ill. Filed Dec. 9, 1901.

The hyphenated word "ESS-THE-DEE" inclosed within lines intended to represent a ribbon with waving ends thereto. Used since November 1, 1901.

38,677. NERVE-TONIC. EDWARD HORMAN BAKER, Des Moines, Iowa. Filed May 15, 1902.

KOLA-ETTES

The word "KOLA-ETTES." Used since August, 1900.

38,678. ALES. BARTHS BREWING COMPANY, Syracuse, N. Y. Filed June 21, 1902.

BRILLIANT

The word "BRILLIANT." Used since September 19, 1894.

38,679. JAVA AND MOCHA COFFEE. HAIG-SMITH TEA & COFFEE CO., Denver, Colo. Filed Apr. 21, 1902.

The words "WEDDING BREAKFAST" and the representation of a wedding party seated around a table, with a woman dressed as a bride in the foreground and distinguished by a long veil. Used since April 1, 1898.

38,680. ROASTED COFFEE. OSCAR H. GERWOLD, Winona, Minn. Filed June 5, 1902.

HUMMER

The word "HUMMER." Used since May, 1897.

38,681. MARMALADE. CORONATION MARMALADE CO., Boston, Mass. Filed May 3, 1902.

CORONATION

The word "CORONATION" and the representation of a crown. Used since April 15, 1901.

38,682. CONSERVING COMPOUND. R. OTTMOSER, a Firm, Hamburg, Germany. Filed Feb. 5, 1901.

Garantol

The word "GARANTOL." Used since February, 1897.

38,683. TABLE-SYRUP AND MOLASSES. THE TOWLE SYRUP COMPANY, St. Paul, Minn. Filed June 12, 1902.

A-CORN

The hyphenated word "A-CORN" and the representation of an acorn. Used since April 7, 1902.

38,684. COMPOUND FOR EXTRACTING GREASE. THEODORE H. PRICE, New York, N. Y. Filed May 23, 1902.

NAILITZA

The word "NAILITZA." Used since September 1, 1879.

38,685. CERTAIN NAMED WASHING COMPOUNDS. CHARLES C. GERHART, Clarksville, Tenn. Filed May 21, 1902.

CLEANO.

The word "CLEANO." Used since March 17, 1902.

38,686. WITHDRAWN.

38,687. SOAP. FRANK M. COULTER, Los Angeles, Cal. Filed May 13, 1902.

LEMOLA

The word "LEMOLA." Used since August 3, 1901.

38,688. CARBOLIC ACID AND PREPARATIONS CONTAINING SAME. F. C. CALVERT & CO., Bradford, Manchester, England. Filed Apr. 26, 1902.

Four arrows in the form of a cross diverging from a central disk to the circumference of a circle described around their points. Used since August, 1861.

38,689. PRINTING-INKS. SIGMUND ULLMAN CO., New York, N. Y. Filed May 21, 1902.

DOUBLETONE

The word "DOUBLETONE." Used since January 1, 1902.

38,690. INK FOR FINISHING EDGES AND HEELS OF BOOTS AND SHOES. S. A. WHITE CO., Boston, Mass. Filed Apr. 21, 1902.

MINITINK

The word "MINITINK." Used since January 23, 1902.

38,691. PAINTS. NAAMLOOZE VENNOOTSCHAP NEDERLANDSCHE VERFFABRIEK "ECLATIN," Amsterdam, Netherlands. Filed June 23, 1902.

ECLATIN

The word "ECLATIN." Used since May 9, 1901.

38,692. PAINTS AND ROOFING-PAINT. LEWIS ALLEN TERRY, Cleveland, Ohio. Filed June 16, 1902.

GRAPHAULT

The word "GRAPHAULT." Used since February 15, 1902.

38,693. BITUMINOUS COMPOSITION OR CEMENT. WARREN BROTHERS COMPANY, Boston, Mass. Filed Apr. 7, 1902.

TAROLITHIC

The word "TAROLITHIC." Used since January 1, 1902.

38,694. CERTAIN NAMED CEMENT. THE CLARK CAST STEEL CEMENT CO., Huntington, Conn. Filed June 19, 1902.

CAST STEEL.

The words "CAST STEEL." Used since November 1, 1900.

38,695. PRIMARY ELECTRIC CELLS. PORTABLE ELECTRIC POWER & LIGHT COMPANY, Jersey City, N. J. Filed June 11, 1902.

PORT ELEC

The representation of a portable electric primary cell with handle attached and lamp thereupon, with rays of light radiating therefrom, and the combination of letters "PORT ELEC" twice displayed. Used since May 22, 1902.

38,696. PORTABLE ELECTRIC AND OIL LAMPS AND LANTERNS. 20TH CENTURY M'F'G CO., New York, N. Y. Filed Apr. 28, 1902.

20th CENTURY

The abbreviation and word "20TH CENTURY." Used since November 15, 1901.

38,697. INCANDESCENT ELECTRIC LAMPS. BRYAN MARSH COMPANY, New York, N. Y. Filed Mar. 11, 1902.

The pictorial representation of a crown, which has a Maltese cross thereon. Used since 1894.

38,698. INCANDESCENT ELECTRIC LAMPS. BRYAN MARSH COMPANY, New York, N. Y. Filed Mar. 11, 1902.

IMPERIAL

The word "IMPERIAL." Used since 1894.

38,699. DRY BATTERIES. THE HUEGHMER ELECTRIC BATTERY CO., Cleveland, Ohio. Filed May 19, 1902.

THE 1900

The word and figures "THE 1900." Used since May 1, 1897.

38,700. PNEUMATIC TIRES FOR BICYCLES, CARRIAGES, AND AUTOMOBILES. FISK RUBBER COMPANY, Chicopee Falls and Springfield, Mass. Filed June 20, 1902.

PREMIER

The word "PREMIER." Used since November 22, 1900.

88,701. CERTAIN NAMED HEATING APPARATUS. PIERCE, BUTLER AND PIERCE MFG. CO., Syracuse, N. Y. Filed Nov. 14, 1901.

LOURAINE

The word "LOURAINE." Used since March 16, 1901.

88,702. WEIGHING-SCALES. THE H. H. SUBAIT MFG. CO., Kansas City, Kans. Filed June 3, 1902.

MONARCH

The word "MONARCH." Used since September 1, 1899.

THE NORRIS PETERS CO.

LABELS

REGISTERED JULY 29, 1902.

9,321.—*Title:* "CAST STEEL CEMENT." (For Cement.) THE CLARK CAST STEEL CEMENT CO., Huntington, Conn. Filed July 1, 1902.

9,322.—*Title:* "LAS AMERICAS." (For Cotton Cloth.) D. A. DE LIMA & Co., New York, N. Y. Filed July 2, 1902.

9,323.—*Title:* "KEMPSHALL FLYER." (For Golf-Balls.) THE KEMPSHALL MANUFACTURING COMPANY, Arlington, N. J. Filed July 1, 1902.

9,324.—*Title:* "KEMPSHALL LEAGUE." (For Golf-Balls.) THE KEMPSHALL MANUFACTURING COMPANY, Arlington, N. J. Filed July 1, 1902.

9,325.—*Title:* "VICTOR RECORD." (For Sound-Records.) VICTOR TALKING MACHINE CO., Camden, N. J. Filed July 1, 1902.

9,326.—*Title:* "MONARCH RECORD." (For Sound-Records.) VICTOR TALKING MACHINE CO., Camden, N. J. Filed July 1, 1902.

9,327.—*Title:* "AMMONIA CELERY." (For Medicine.) THOS. KELLY & SON, Baltimore, Md. Filed July 2, 1902.

9,328.—*Title:* "SPRAYINE." (For Medicine.) FRANK W. ROBINSON, McLeansboro, Ill. Filed July 5, 1902.

9,329.—*Title:* "CYBELINE." (For Dandruff Cure.) GEORGE L. TYLER, Auburn, N. Y. Filed June 16, 1902.

9,330.—*Title:* "STORY'S FOOT RELIEF." (For Foot-Powder.) FABRIKOID COMPANY, Newburgh, N. Y. Filed July 2, 1902.

9,331.—*Title:* "ALDERNEY BAKING POWDER." (For Baking-Powder.) THE NATIONAL LABEL CO., Cincinnati, Ohio. Filed July 3, 1902.

9,332.—*Title:* "MAIZE LOAF." (For Cereal Food.) GORDON AND RICHARDSON, St. Marys, Ohio. Filed July 1, 1902.

9,333.—*Title:* "REX PORK AND BEANS." (For Pork and Beans.) THE CUDAHY PACKING CO., Chicago, Ill., and South Omaha, Nebr. Filed June 30, 1902.

9,334.—*Title:* "COMPLIMENTS OF THE SEASON." (For Cigars.) AMERICAN LITHOGRAPHIC COMPANY, New York, N. Y. Filed July 2, 1902.

9,335.—*Title:* "PRIMUS." (For Bottled Beer.) BARKER & WHEELER CO., Peoria, Ill. Filed July 3, 1902.

9,336.—*Title:* "OTTOMAN." (For Cigars.) LINCOLN, SEYMS & CO., Hartford, Conn. Filed July 2, 1902.

DECISIONS

OF THE

COMMISSIONER OF PATENTS

AND OF

UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

EX PARTE PARKER, HOLMES & COMPANY.

Decided January 2, 1903.

1. TRADE-MARK—"WAUKWELL" FOR SHOES—NOT DESCRIPTIVE.
The word "Waukwell" as a trade-mark for shoes *Held* registrable, since it is not descriptive of the shoes.
2. SAME—ANTICIPATION—"WAUKWELL"—"WALKEASY."
Held that the trade-mark "Waukwell" is not anticipated by the prior marks "Walkeasy" and "Walk-a-way" for the same class of goods, since purchasers exercising ordinary care would not confuse the marks and be misled.

ON appeal.

TRADE-MARK FOR FOOTWEAR, ETC.

Application for registration filed March 11, 1901, No. 62,872.

Messrs. Macleod, Calver & Randall for the applicant.

ALLEN, *Commissioner:*

This is an appeal from the decision of the Examiner of Trade-Marks refusing to register the word "Waukwell" as a trade-mark for footwear.

Registration was refused on the ground that the mark is descriptive and also on the ground that it so nearly resembles prior registered marks as to cause confusion in the minds of purchasers. The prior marks are "Walkeasy" and "Walk-a-way," applied to the same class of merchandise.

It is believed that "Waukwell" differs from "Walkeasy" to such an extent that a purchaser desiring the goods of one party and using the ordinary care which is to be expected of him in his efforts to obtain those goods would not be confused by the two marks and take the goods of one supposing them to be those of the other. The registration of "Walkeasy" therefore does not prevent the subsequent registration of "Waukwell." "Walk-a-way" differs still more from the applicant's mark than does "Walkeasy."

The word "Waukwell" as applied to shoes may by some persons be construed as meaning that one wearing these shoes will walk well, and that this will be accomplished by means of the shoes, and that thus "Waukwell" is descriptive of shoes.

This view, however, excludes other reasons equally probable to explain the quality of the walk. This may result from many causes, among which weather, health, and clothing might be enumerated, and to apply all this inference to the shoes in order to find the term descriptive of them is thought to be unwarranted.

The decision of the Examiner of Trade-Marks is reversed.

EX PARTE BUSTIN.

Decided May 15, 1902.

1. DIVISION—VESSEL—HULL AND RUDDER.
Held that division was properly required between claims to the external configuration of the hull of a vessel and claims to the means for mounting the rudder, since they are recognized as independent subjects of invention and are separately classified in this Office.
2. SAME—SAME—MEANS FOR PROPELLING VESSELS—INDEPENDENT INVENTION.
Held that claims covering the means for propelling the ship should be claimed in a separate application from claims to the shape of the hull and to the means for mounting the rudder.

ON petition.

NAVIGABLE VESSELS.

Application of Charles A. Bustin filed October 22, 1901, No. 79,537.

Mr. Charles S. Champion for the applicant.

ALLEN, *Commissioner:*

This is a petition from the Examiner's requirement of division between certain groups of claims in the above-entitled application on the ground that each group covers an independent and separate invention from those covered, respectively, by the other groups of claims.

The record shows that the application as filed contained eighty-four claims. The Examiner held that these claims covered six independent inventions and required that the application be divided, so that the further prosecution of the case should be confined to one invention.

The petitioner responded by amending certain claims and canceling others. Among the claims canceled from the application were those forming two groups of claims covering, respectively, the hatch construction and the oil-spraying device. The Examiner was then requested to withdraw his requirement for further division. On reconsideration the requirement was adhered to, from which action this petition was taken.

The Examiner is of the opinion that the remaining claims cover four separate and independent inventions. He has grouped them as follows: claims 1 to 37, inclusive, as covering the external configuration of the hull; claims 38 to 55, inclusive, and claims 59, 60, 61, and 63 as covering the form of the hull, with the construction and location of the propelling apparatus; claims 56, 57, 58, 62, 64, 65, and 66 as covering the details of the propelling apparatus, and claims 67, 68, and 69 as covering the particular means of mounting the rudder.

It is pointed out that the invention covered in the first and last groups of claims belong, respec-

tively, in the subclasses of "Form" and "Steering mechanism, rudders," of class 114, Ships. Not only are these two inventions recognized by this Office in its scheme of classification as being independent of each other, but they are recognized by inventors and manufacturers as independent objects of manufacture and sale, and from this it results that these devices possess a capacity for independent use. Division was properly required between claims 1 to 37, inclusive, and claims 67, 68, and 69.

Of the remaining claims those numbered 38, 39, 51, 52, 53, 54, 56, 57, 58, 63, 64, 65, and 66 cover inventions classified in class 115, Marine Propulsion, which are recognized by inventors and manufacturers as distinct and independent subjects-matter of invention and possess a capacity for independent use from those inventions covered in the first and last groups of claims, which are classified in the class of "Ships." The requirement of division between the groups of claims covering inventions, respectively, in "Marine Propulsion" and in "Ships" was a proper one. The claims specified by the Examiner as forming the group which covers the invention in "Marine Propulsion" should, however, be extended to include claims 38, 39, 51, 52, 53, and 54, as above indicated.

Claims 40 to 50, inclusive, claim 55, and claims 59 to 62, inclusive, which include both the construction of the hull and the location and construction of the propelling mechanism, may be prosecuted in the same application, either with claims 1 to 37, inclusive, which cover the hull, or with those claims which are held to cover the propelling mechanism, as the petitioner may elect.

The petition is granted to the extent indicated.

EX PARTE REGINA MUSIC BOX COMPANY.

Decided July 8, 1902.

1. LABEL—COMMISSIONER OF PATENTS DETERMINES LAWFULNESS.
The Commissioner of Patents is authorized and required to determine whether the thing presented for registration is a label and complies with the requirements of the law. He is not required to register everything which is presented and called a label.

2. SAME—MUST BE DESCRIPTIVE AS WELL AS ARTISTIC.
A label to be registrable in the Patent Office must not only possess artistic merit, but must be descriptive of the article for which it is used.

3. SAME—FOR ARTICLE OF MANUFACTURE—DESCRIPTIVE.
A mere statement by the applicant for registration that he intends to use the design presented upon a particular article of manufacture does not make it *for* that article within the meaning of the law. The indication of the article must be in the label itself.

4. SAME—REGISTRABILITY DETERMINED BY INTRINSIC QUALITIES.
The registrability of a label must be determined by its intrinsic qualities and not by some possible or contemplated use of it.

ON appeal.

LABEL FOR MUSIC-BOXES.

Application filed April 5, 1902, No. 2,701.

Messrs. Briesen & Knauth for the applicant.

ALLEN, *Commissioner:*

This is an appeal from a decision of the Examiner refusing to register a label entitled "Regina" to be used for music-boxes.

It is admitted that the label presented for registration is an intellectual and artistic production; but registration has been refused because there is nothing about it which indicates that it is used on music-boxes.

It is contended by appellant that—

> the statute has not defined what shall be considered a label whether it shall be a picture or a writing; whether it shall be descriptive of the article to which it is affixed; or whether it may be a mere arbitrary design—

and that therefore the Commissioner must register a label though it may not be descriptive. This contention is based upon the decision of the Supreme Court of the District of Columbia in *The United States, ex rel. Schumacher*, v. *Marble, Commissioner of Patents*, (3 Mackey, 32.) In this case the court, after stating the matter quoted above, said:

> If the applicant presents it as a label, and appeals to the Commissioner to give it the protection which the law provides for it as a label, the duty of the Commissioner is to register it, and in doing so he gives it only the protection which the statute provides. * * * With the character of the device the Commissioner is not at all concerned. His function is as purely ministerial as it is capable of being.

This indicates that the Commissioner is not to exercise discretion, but must register anything which is presented as a label. The later decision by the same court, however, in the case of *United States, ex rel. Moodie*, v. *Butterworth* (30 O. G. 97) is ample authority for the opposite conclusion. The court there held that the Commissioner is required to determine whether or not the thing presented is a label and in this must exercise discretion. He must determine whether or not it is a trade-mark, as was done in that case, and it seems equally true that he must determine whether or not it is used—

> for any other article of manufacture—

since section 3 of the act of June 18, 1874, gives him authority to register only such prints or labels as are—

> to be used for any other articles of manufacture.

Under this statute all other engravings, cuts, and prints consisting of—

> pictorial illustrations or works connected with the fine arts—

are to be registered by the Librarian of Congress under the general copyright law.

It seems clear from statements made by the Supreme Court in *Higgins et al.* v. *Keuffel et al.* (55 O. G., 1139) that a label to be registrable in this Office must, aside from other considerations, be descriptive of the article for which it is used. In that case the Court said, speaking of the clause of the Constitution under which Congress is authorized to legislate for the protection of authors and inventors:

> This provision evidently has reference only to such writings and discoveries as are the result of intellectual labor. * * * It does not have any reference to labels which simply designate or describe the articles to which they are attached, and which have no value separated from the articles, and no possible influence upon science or the useful arts. * * * To be entitled to a copyright the article must have by itself some value as a composition, at least to the extent of serving some purpose other than as a mere advertisement or designation of the subject to which it is attached.

The word "label" itself necessarily implies that it is descriptive of the article to which it is applied, and this Office has held that a print or label cannot be held to be "for any other article of manufacture" within the meaning of the statute unless it indicates that article. (*Ex parte Moodie*, 28 O. G., 1271; *ex parte Mahn*, 82 O. G., 1210; *ex parte Barnhart Bros. and Spindler*, 87 O. G., 2118; *ex parte Ball*, 98 O. G., 2366.) The indication must be in the print or label itself and not merely in a statement made by the applicant accompanying it. The print or label is the thing which is registered, and its registrability must be determined by its intrinsic qualities and not by some possible or contemplated use of it. All of the pictures registered by the Librarian of Congress and the arbitrary designs patented under the design law might be applied to china or other articles as ornamentations thereof; but a mere statement by the applicant that he intended to so use them would clearly not warrant this Office in registering them as labels for the articles mentioned. If such a statement of use by the applicant were permitted to determine whether the alleged print or label should be registered in this Office or in the Library of Congress, the distinction attempted to be drawn by Congress between the two classes of artistic productions would be nullified.

It must be held that a label to be registrable in this Office must not only possess artistic merit, but must be descriptive of the article for which it is used.

The alleged label in this case is said by the applicant to be for music-boxes; but the label itself does not indicate this. It is merely an arbitrary ornamental design having the word "Regina" thereon and might very appropriately be used as a trade-mark for various articles.

The decision of the Primary Examiner is affirmed.

DECISIONS OF THE U. S. COURTS.

Court of Appeals of the District of Columbia.

STONE v. PUPIN.

Decided March 5, 1902.

1. INTERFERENCE—PRIORITY—SUFFICIENCY OF DISCLOSURE IN APPLICATION—DECISION OF PATENT OFFICE CONCLUSIVE.
The decisions of the expert tribunals of the Patent Office as to the sufficiency of the disclosure in the original application to support the invention defined in the counts of the issue will be accepted as conclusive by the court in considering questions of priority of invention.

2. SAME—SUFFICIENCY OF DESCRIPTION—LIBERAL CONSTRUCTION.
The fact that the invention oversteps the boundary of pre-existing knowledge both as to structure and scientific principles warrants a liberal view of the scope of the descriptive specifications rather than a narrow and restrictive one.

3. SAME—PRIORITY—DECISION AFFIRMED.
The decision of the Assistant Commissioner (100 O. G., 981) awarding priority of invention to Pupin affirmed.

Messrs. Pollok & Mauro and *Mr. W. W. Swan* for the appellant.

Mr. Thomas Ewing and *Mr. Vernon M. Dorsey* for the appellee.

SHEPARD, *J.:*

This is an interference case involving claims to priority of invention of an improved system of multiplex telegraphy. The invention lies in the arrangement of the receiving-stations in the application of electrical resonance in the art of selective or multiplex signaling, and is embodied in the issue defined in two counts as follows:

> 1. The method of distributing the electrical energy of periodic currents which consists in developing a number of effective currents of different frequencies independently upon a single line and conveying the several energies of these currents each selectively to a separate electrical translating device.
> 2. A system of distribution of electrical energy comprising a main line, means for independently developing effective electromotive forces of different frequencies thereon, branch lines connected with the main line each having its self-induction and capacity so related as to be permeable to alternating currents of a given frequency, and an electrical receiving device in each branch line.

There were three independent claimants in the case when the interference was declared, namely, Pupin, Stone, and Hutin & Leblanc. The order of their applications as filed in the Patent Office is the following: Pupin, February 23, Stone April 4, and Hutin & Leblanc May 9, 1894.

Hutin & Leblanc remained in the case until the final decision of the Commissioner of Patents from which they took no appeal.

Pupin made an amendment of his specifications in March, 1895, and Stone thereafter moved to have him declared the junior party in accordance with a practice sometimes pursued in the Patent Office. Shortly thereafter, Stone filed an additional motion to dissolve the interference. Both motions were founded on the ground that the amendment introduced new matter constituting an entire departure from the invention originally claimed.

These motions were heard by the Primary Examiner who had declared the interference. In the beginning of an elaborate opinion, he stated that there was great difficulty in determining the question presented—

> occasioned by the fact that the issues of the interference relate to and cover an art which from its technological side involves a radical departure from previous electrical systems, and which from its theoretical side utilizes electrical principles which at the date of these respective inventions were but little understood, and are even now not worked out in detail or rigorously apprehended.

Coming then particularly to the invention of the issue he styled it one—

> which not only oversteps the boundary of pre-existing knowledge in the matter of the concrete devices and operations employed, but in its theoretical aspect goes well beyond the obvious application of known scientific principles to the production of new results and systems.

His conclusion was that there was no foundation for charging Pupin with changing his claims from one specific invention to another, hence the motion to dissolve was overruled. But because his amendment "omitted a limitation from his claims and from his description, and has set forth his invention in a broader light, both in the specifications and in the claims," he granted the motion to make Pupin the junior party, thereby shifting the burden of proof. This, in his opinion, was the necessary result, of broadening "his claims from a specific invention to a more generic statement of the invention."

No appeal was taken from this decision and testimony was taken in the order thereby indicated.

A number of experts were examined on the question whether the original application of Pupin disclosed the invention of the issue; and other evidence was introduced relating to the conception,

disclosures, and experimentation of the parties. The entire record consists of nearly seventeen hundred pages.

The Examiner of Interferences discussed the evidence at length, and finding no material discrepancy between the original and amended specifications, awarded priority to Pupin as the first to conceive, and reduce to practice—giving each party constructive reduction only through application filed.

The Examiners-in-Chief, to whom an appeal was taken by both of the losing parties, show in their decision a careful and thoughtful examination of the terms of Pupin's original specifications, and, as stated, had "no difficulty in finding therein a complete disclosure of the invention of each issue."

Passing then to the consideration of the evidence of his conception, they said:

Pupin's evidence impresses us as truthful; it is consistent with the probabilities of the case, and is corroborated by O'Connor as to the actual construction of a model device which disclosed all of the elements called for by the second count of the issue, and which was undoubtedly operated in the manner called for by the first count, even though the results were not so satisfactory as to entitle the device to be regarded as a reduction to practice. We regard the evidence sufficient to prove that Pupin had a conception of the invention of both counts of the issue in 1890, and that he constructively reduced the invention to practice by the filing of his application February 28, 1894.

Upon a review of the evidence on behalf of Stone and Hutin & Leblanc, they concluded that their conceptions followed that of Pupin, and that neither had done anything practically toward adapting and perfecting the invention for use.

On the other hand, they found that Pupin had—

experimentally worked out quantitative methods of measurement of circuits containing localized induction and capacity, determined the effect of iron in the cores on such circuits, and benefited the public by the disclosure of his work.

The Assistant Commissioner before whom the case came on further appeal, agreed with the Examiners-in-Chief, that Pupin "was the first to conceive the invention, the first to constructively reduce it to practice, and the only one to actually reduce it to practice," and, therefore, affirmed their decision.

In reaching a conclusion he did not content himself with adopting their decision but carefully reexamined the questions involved, reviewing particularly the evidence relating to the conception and development of the invention by each of the respective claimants.

The chief weight of the argument on this final appeal, in which Stone is the sole appellant, has been directed to the contention founded on the insufficiency of Pupin's original specifications.

In respect of this we must accept the decisions of the tribunals of the Patent Office as conclusive. (*Ostergren* v. *Tripler*, 17 App. D. C., 557, 559; 95 O. G., 837; *Schupphaus* v. *Stevens*, *Idem*, 548, 555, 95 O. G., 1452, and cases cited.)

The fact that—

the issues deal with an invention which not only oversteps the boundary of preëxisting knowledge in the matter of the concrete devices and operations employed, but in its theoretical aspect goes well beyond the obvious application of known scientific principles to the production of new results and systems—

as declared by the Primary Examiner in disposing of the motions before referred to, would seem rather to warrant a liberal view of the scope of the descriptive specifications, than a narrow and restrictive one. Moreover, the abstruseness of the art to which the invention belongs renders it all the more obligatory to accept the concurring decisions of the expert tribunals of the Patent Office. (*In re Beswick's Appeal*, 16 App. D. C., 345, 350; 91 O. G., 1436.)

We see no good purpose that would be served by again reviewing the evidence relating to the efforts of Pupin, after conception and in the course of his actual reduction to practice.

This has been fairly done in the decisions appealed from and nothing material could be added thereto. Upon a careful consideration of the evidence, we entirely concur in their conclusions.

Nothing remains but to affirm the decision appealed from, and to order this decision with the proceedings herein to be certified to the Commissioner of Patents as required by law; and the same is accordingly done.

Patent and Trade-Mark Registration in Cuba.

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE,
Washington, D. C., July 21, 1902.

The subjoined correspondence, transmitted through the Honorable Secretary of the Interior, is published for the information of those whom it may concern.

E. B. MOORE,
Acting Commissioner.

DEPARTMENT OF STATE,
Washington, D. C., July 9, 1902.

SIR: I have the honor to inclose for your information copy of a note from the Cuban Minister at this capital transmitting the regulations of his government for the registration of United States patents and trade-marks in Cuba.

I have the honor to be, sir,
Your obedient servant,
JOHN HAY.

The Honorable the Secretary of the Interior.

[Translation.]

LEGATION OF CUBA,
Washington, D. C., July 5, 1902.

EXCELLENCY: In pursuance of instructions from my government, I have the honor to transmit to Your Excellency the communication addressed to the Department of State by the Department of Agriculture, Commerce and Industry under date of June 21 last, as follows:

SIR: I have, on this day, directed the announcement of the following decision. The military government of the United States in this Island having come to an end, and the circulars Nos. 12 and 21, respectively dated April 11 and June 1, 1899, issued by the Division of Customs and Insular Affairs of the War Department of Washington in respect to the registration of American trade-marks and patents having in consequence become void and null, by virtue of their text itself, since those circulars were issued for the territories subject to the military government of the military forces of the United States, I have decided that patents and trade-marks of all descriptions, printed matter, titles and labels, duly registered in the Patent Office of the United States, for whose protection in this Island application shall hereafter be made, from this date, by filing the same, shall be registered in the department of which I have charge if admissible, upon observing the procedure followed for the registration of those of other countries and upon the payment of $25.00 currency for patents and of $12.50 currency for trade-marks, prints, etc., that is to say the same fees as are paid by the other foreign and national marks and patents, in lieu of the one peso, currency, indicated with regard to the American, in said circular No. 21.

I avail myself of this opportunity, etc.

GONZALO DE QUESADA.

To H. E. The Hon. JOHN HAY,
Secretary of State of the United States.

Patents Nos. 706,002 to 706,507.

Photographic Copies of Drawings.

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE,
Washington, D. C., July 1, 1902.

The Patent Office is now prepared to furnish black line on white ground copies of any unbound drawing, foreign or domestic, which may be in its possession, instead of the blue-prints heretofore furnished. Only the 7x11 (patent) size and the full or 10x15 size prints will hereafter be furnished, at 15 and 25 cents per sheet, respectively.

Copies of drawings of pending, abandoned, forfeited, or informal cases and of caveats may be had in either of the above-named sizes except when they are to be certified, in which case they must be the 10x15 size.

Copies of United States or foreign patent drawings will be made only in the 10x15 size.

When ordering copies of foreign patent drawings, either the serial number of the applications in which they were cited as references or the class and subclass where they may be found must be given. The title of the invention or the number of the division will not be sufficient. Bound volumes cannot be used for making prints. Failure to give the fullest data whereby the mounted drawing may be found will result in delay and unnecessary correspondence.

The work will be much facilitated if a separate order be made for each drawing. The Office will furnish, gratuitously, blanks for this purpose on request.

As a result of abolishing the small (5x8) size the requirement that duplicate prints must be ordered in certain cases will no longer be enforced. The requirement that less than all the sheets of a case will not be printed unless there is already a full set in the file will not be insisted upon; but applicants or attorneys are strongly urged to file a set of prints or order them to be made by the Office at the time of filing an application. Such procedure will save delay later if correction of the drawing is desired or required.

F. I. ALLEN,
Commissioner.

Revision of Trade-Mark Rules.

(ORDER No. 1,465.)

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE,
Washington, D. C., April 8, 1902.

Rule 21, subdivision (*b*,) governing the registration of trade marks, is hereby amended to read as follows:

(*b*) A statement specifying name, domicile, location, and citizenship of the party applying; the class of merchandise and the particular description of goods comprised in such class to which the particular trade-mark has been appropriated; a description of the trade-mark itself, and a statement of the mode in which the same is applied and affixed to goods, and the length of time during which the trade-mark has been used, and if the applicant be a corporation it must set forth under the laws of what State or nation incorporated.

F. I. ALLEN,
Commissioner.

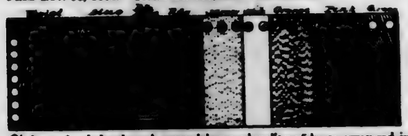
Patents to Assignees.

RULE 201. In every case where it is desired that the patents shall issue to an assignee the assignment must be recorded in the Patent Office at a date not later than the day on which the final fee is paid. (See Rule 36.) The date of the record is the date of the receipt of the assignment at the Office.

PATENTS

GRANTED AUGUST 5, 1902

706,002. KEYBOARD. GEORGE G. ALLEN, Malden, Mass., assignor to Stenotype Company, Portland, Me., a Corporation of Maine. Filed Nov. 11, 1899. Serial No. 611,769. (No model.)



Claim.—1. A keyboard comprising a plurality of keys arranged in parallel rows, each row being a duplicate of the other and divided into a series of sections indicated by different colors, and the name of each color being indicative of the letters grouped therein, whereby a glance at any color suggests to the operator the letters embraced therein, and it is unnecessary to mark every key with the character it represents, substantially as set forth.

2. A keyboard comprising a plurality of keys arranged in parallel rows, each row being a duplicate of the other and divided into a series of groups, and a background for said keys composed of sections each differently colored from the others, the name of each color being indicative of the letters grouped therein, substantially as set forth.

3. A keyboard comprising a plurality of keys arranged in parallel rows, each row being a duplicate of the other and the keys being arranged in groups; and a background for said keys divided into sections corresponding with said groups, the name descriptive of the surface of each section being indicative of the letters grouped therein, substantially as set forth.

4. A keyboard comprising a plurality of keys arranged in groups indicated by different colors, the characters in each group being suggested phonetically by the name of the color associated therewith.

706,008. WHEEL-HUB. CHRISTIAN ANDERSON, Indianapolis, Ind. Filed Dec. 21, 1901. Serial No. 86,330. (No model.)

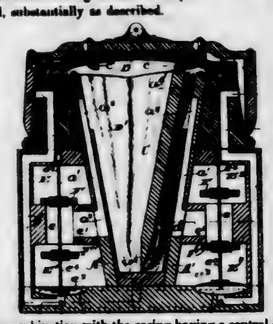
Claim.—1. A wheel-hub composed of a wooden center and two metal shells extending over the same, said shells being provided with interior inwardly-extending curved flanges and composed of compressible metal which is compressed in finishing the hub, substantially as set forth.

2. The combination in a wheel-hub, of the wooden center A, and the metal shells B and C, said shells being provided with the inwardly-extending flanges and teeth *f* and *i*, substantially as set forth.

706,004. PNEUMATIC MOTOR. GUSTAF B. ANDERSON, Chicago, Ill. Filed Aug. 2, 1901. Serial No. 70,697. (No model.)

Claim.—1. The combination with a casing having a central opening and air passages and chambers communicating therewith, of valves to open and close said passages, two bellows located in said opening, means to inflate and deflate a portion of each of the bellows alternately, a power wheel or pulley journaled near the casing and means connecting the pulley and bellows whereby the pulley is rotated, substantially as described.

2. The combination with a casing having a central opening and air chambers and passages communicating therewith, of valves to open and close said passages, two bellows located in said opening, a movable piece in each of the bellows, means to inflate and deflate a portion of each of the bellows alternately, a power wheel or pulley journaled near the casing, pitman-rods connecting the movable pieces of the bellows and the power-wheel, substantially as described.



3. The combination with the casing having a central opening and air chambers and passages communicating therewith, of valves to open and close said passages, two bellows located in said opening, a movable piece in each of the bellows, means to inflate and deflate a portion of the bellows alternately, a power wheel or pulley journaled near the casing, pitman-rods connecting the movable pieces of the bellows and the power-wheel, a bar located above each of the bellows and connected at its ends to valves for closing the external openings of the casing, means on each of said bars to engage the upper portion of the movable pieces of the bellows, substantially as described.

4. The combination with a casing having a central opening and air passages and chambers communicating therewith, of valves to open and close said openings, two bellows located in said opening, a movable piece in each of the bellows and having on its upper end an outward extension, means to inflate and deflate the bellows alternately, a power wheel or pulley journaled near the casing, pitman-rods connecting the movable pieces of the bellows and the power-wheel, a bar extending over each of the bellows and having on its lower surface downward projections, valves at each end of each of said bars to close the external openings in the upper part of the casing, a pulley journaled above each of said bars, a spring on each of said bars and in contact with the pulleys, substantially as described.

706,005. ACTUATING MECHANISM FOR AWNINGS. WILLIAM H. ANGELL, Oakland, Cal. Filed Oct. 14, 1901. Serial No. 78,022. (No model.)

Claim.—1. In a mechanism of the character described, the combination of a casing having front and back walls provided with bearings, and also having upper and lower portions provided with a circular bore and a socket, respectively, a gear interposed between the upper and lower portions of the casing and having a bore of angular form in cross-section, a shaft journaled in the upper portion and stepped in the lower portion of the casing and having a portion of angular form in cross-section occupying the bore of the gear, a gear formed of one piece, interposed between and journaled in the bearings of the front and back walls of the casing and having teeth intermeshed with those of the gear on the shaft, and also having ratchet-teeth, a detent arranged to engage said ratchet-teeth, and suitable means for rotating the gear bearing the two kinds of teeth.

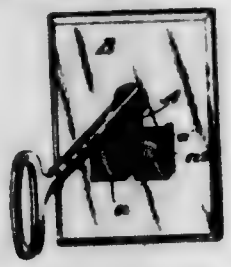
2. In a mechanism of the character described, the combination of a casing, a shaft journaled therein, a gear fixed on the shaft so as to turn

therewith, a gear formed of one piece, interposed between and journaled in opposite walls of the casing and having teeth intermeshed with those of the gear on the shaft, and also having ratchet-teeth, a detent for engaging said ratchet-teeth, and suitable means for rotating the gear bearing the two kinds of teeth.

3. In a mechanism of the character described, the combination of a casing having a bearing in its back wall and a circular aperture in its front wall, and also having upper and lower portions provided with a circular bore and a socket, respectively, a gear interposed between the upper and lower portions of the casing and having a bore of angular form in cross-section, a shaft journaled in the upper portion and stepped in the lower portion of the casing and having a portion of angular form in cross-section occupying the bore of the gear, a gear formed of one piece interposed between and journaled in the front and back walls of the casing and having an angular socket in its outer end, and teeth intermeshed with those of the gear on the shaft, and also having ratchet-teeth, a detent for engaging said teeth, and a crank having an angular stem corresponding to and removably arranged in the angular socket of the gear bearing the two kinds of teeth.

4. In a mechanism of the character described, the combination of a casing, a shaft journaled therein, a gear fixed to the shaft so as to turn therewith, a gear mounted in the casing and intermeshed with the gear on the shaft, ratchet-teeth fixed with respect to said latter gear, a pivoted detent adapted to engage the ratchet-teeth, a slide movable in the casing, in a position to engage the detent, and having a finger-piece extending through a slot in a wall of the casing, and a spring connected to and movable with the slide, and arranged to bear against the casing.

706,006. KEY-GUARD. BYRON R. BACON, South Orange, N. J. Filed Nov. 7, 1901. Serial No. 81,365. (No model.)

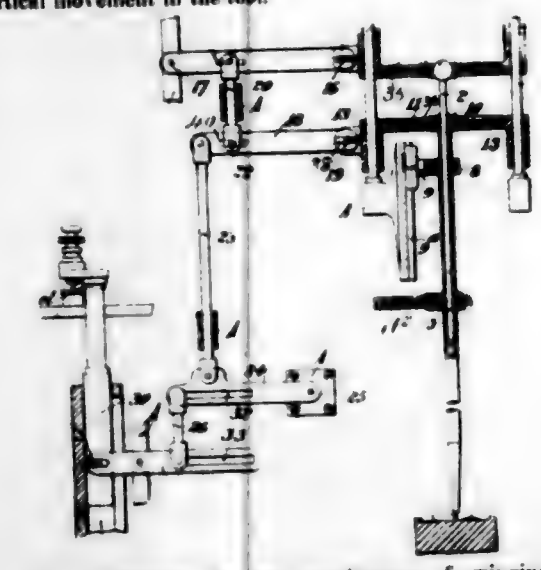


Claim.—1. In a key-guard consisting of a continuous strip of springy metal formed with parallel shanks adapted to be inserted through the key-hole of an escutcheon, projecting lips formed upon the said shanks and adapted to engage upon the inner side of the escutcheon, ledges or shoulders formed at the ends of the said shanks, and inwardly-turned edges formed along the outer ends of the said ledges or shoulders and adapted to engage against the outer side of the said escutcheon, substantially as described.

2. In a key-guard consisting of a continuous strip of springy metal bent to form shanks which are adapted to be inserted through the key-hole of an escutcheon, lips or lugs formed upon the said shanks and adapted to engage upon the inner side of the escutcheon, ledges or shoulders formed upon the ends of said ledges, and ridges or finger-recesses formed upon the said ledges, substantially as described.

706,007. PANTOGRAPH ENGRAVING-MACHINE. MARK BARR, Broadheath, England, assignor to the Linotype Company, Ltd., London, England. Filed Jan. 4, 1900. Serial No. 344. (No model.)

Claim.—1. The combination of swinging compound tracer-rod consisting of two portions telescopically connected together; two horizontal plates, one jointed to each portion of the said rod and capable of a reciprocating vertical motion; a lever-and-link mechanism from the horizontal plate of that portion of the tracer-rod that carries the tracer-point, to the tool, adapted to transmit to the latter, the vertical movements or vertical components of the movements of the tracer-point; and a connection between the two horizontal plates to prevent a lateral movement or a lateral component of a movement of the tracer-rod, producing a corresponding vertical movement in the tool.

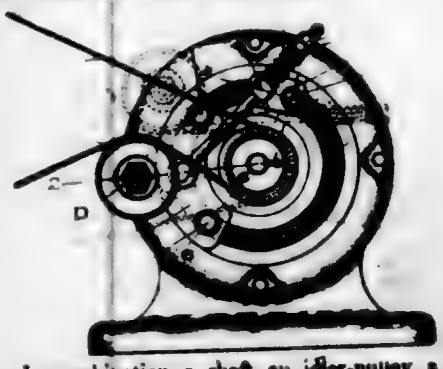


2. The hereinbefore-described combination of swinging compound tracer-rod having a bottom and outer portion adapted to slide over the top and inner portion; a connection fast to the said inner portion for limiting its motions to one and the same horizontal plane; a horizontal plate jointed to the top end of the said top and inner portion and capable of a reciprocating vertical motion; a horizontal plate jointed to the top end of the said bottom and outer portion and capable of a reciprocating vertical motion; a lever having a fixed fulcrum at one end and its opposite end connected to the horizontal plate of the said top and inner portion; a lever connected to the horizontal plate of the said bottom and outer portion of the tracer-rod; a link connecting the two levers and a link-and-lever mechanism establishing a connection between the last-mentioned lever and the tool to transmit the vertical movements or vertical components of the movements of the said bottom and outer portion of the tracer-rod to the tool.

706,008. SASH-BALANCE. JACOB BARROW, Windfall, Ind. Filed July 27, 1901. Serial No. 69,969. (No model.)

Claim.—In a lock for sashes operated in the manner described, the combination of a bracket, a circular block eccentrically journaled therein, the said block having an aperture which is normally arranged at an angle to the vertical line of the sashes, and a rope engaging the sashes and lock whereby through the weight of the upper sash the cord is held in the lock, and a cord for operating the lock, substantially as shown and described.

706,009. BELT-TIGHTENER. NORMAN C. BARRETT, Boston, Mass., assignor to General Electric Company, a Corporation of New York. Filed Dec. 5, 1900. Serial No. 38,718. (No model.)



Claim.—1. In combination, a shaft, an idler-pulley, a support for the pulley which is concentrically adjustable around the shaft, a second support also concentrically adjustable about the shaft, and a spring located between the pulley and the second support and acting on the pulley in a manner to keep the belt tight.

2. A belt-tightener mounted adjacent to a shaft, means whereby it can be adjusted concentrically with reference to said shaft, and means for

exerting a spring-pressure on said tightener in any angular position to which it is moved.

3. A belt-tightener comprising an idler-pulley, a support for said pulley adjustable to any angular position with reference to the driving-pulley, and a spring-actuated rod attached to said support.

4. The combination with a movable idler-pulley, of a spring-actuated rod attached thereto, a support for the pulley which is movable bodily, and a movable support for said rod.

5. The combination of a driving-pulley, of an idler-pulley, a movable support for the idler-pulley, a rod pivoted to said support, an adjustable abutment through which said rod passes, nuts on the rod, and a spring compressed between the abutment and said nuts.

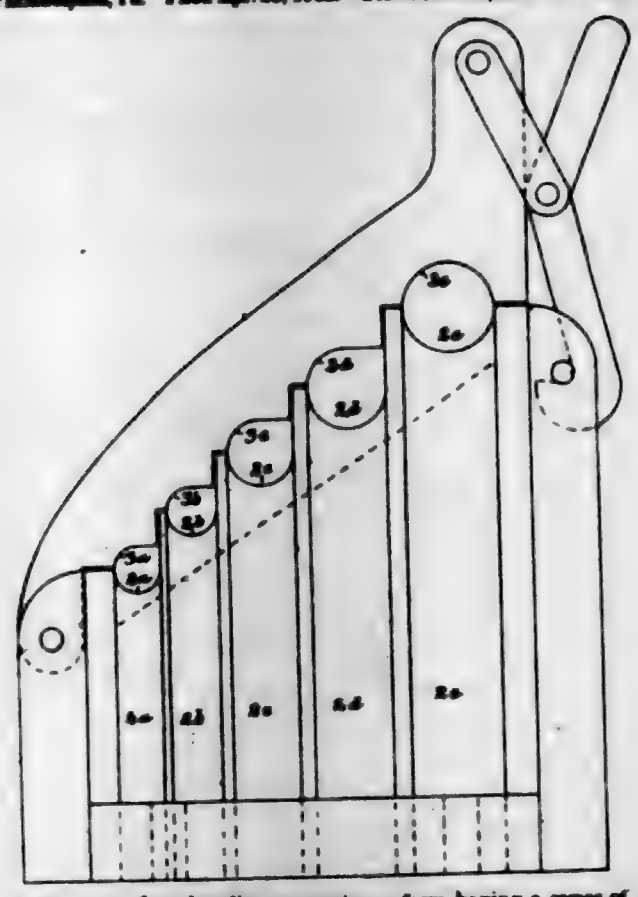
6. The combination with a driving-pulley and its shaft, of a bearing therefor containing a groove concentric with the shaft, a plate adjustable along said groove, an idler-pulley supported by said plate, and a spring which tends at all times to hold the pulley against a belt.

7. The combination with a driving-pulley and its shaft, of a bearing therefor containing a groove concentric with the shaft, a plate adjustable along said groove, an idler-pulley supported by said plate, a block also adjustable along the groove, and a yielding connection between the plate and the pulley.

8. The combination with a driving-pulley and its shaft, of a bearing therefor containing a groove concentric with the shaft, a plate adjustable along said groove, an idler-pulley supported by said plate, a block having a clamping-bolt engaging with the groove, and a spring-actuated rod pivotally attached to the plate and to the pulley.

9. The combination with an electric motor having an undercut groove in its casing concentric with the shaft, of a segment-plate adjustably mounted in the groove, bolts for connecting said plate with said grooved casing, an idler-pulley mounted on said plate, a block having a clamping-bolt engaging with said grooved casing, an eyebolt pivoted in the block, a rod pivoted to the plate and passing through the eyebolt, a spring on the rod, and means for compressing it against the eyebolt.

706,010. **PIPE-BENDING APPARATUS.** WILLIAM W. BENSON, Philadelphia, Pa. Filed Apr. 30, 1902. Serial No. 105,269. (No model.)

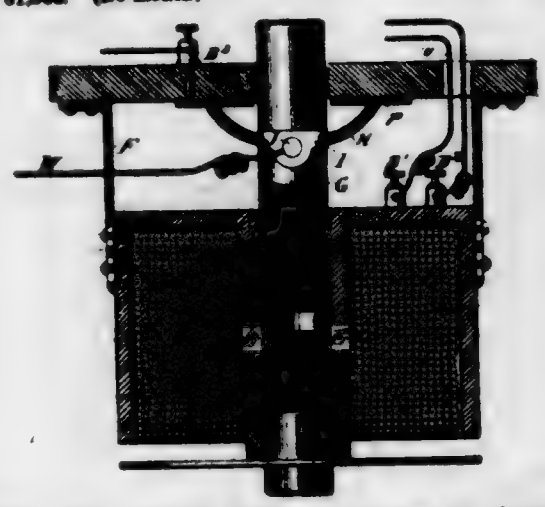


Claim.—1. In a bending apparatus, a form having a series of parallel circular grooves of varying radii, in combination with a base for supporting the same and holding the articles to be formed by the respective grooves, said mechanism being provided with apertures adjacent to the respective grooves for engaging the article to be formed, substantially as specified.

2. In a bending apparatus, the combination of a base having a series of holes therein adapted for engaging pipe ends, with a curved block or form having a series of peripheral grooves of varying radii extending from the respective holes, and a lever adapted to cross said grooves transversely and retain the shapes formed upon said apparatus, substantially as specified.

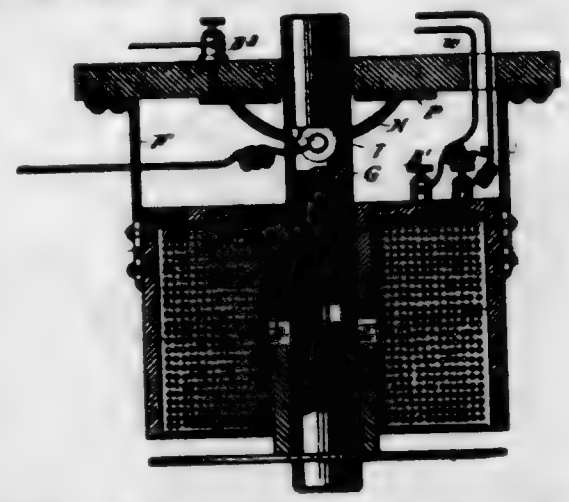
3. In a bending apparatus, the combination of a base having a series of holes therein adapted for engaging pipe ends, with a block or form having peripheral grooves of varying radii extending from the respective holes, said device having the form substantially of a cone-frustum section axially intersected by said base, and a hinged lever having a latch adapted for holding the shapes formed upon said apparatus.

706,011. **ART OF CONTROLLING ELECTRICAL SWITCHES OPERATED BY ELECTROMAGNETS.** FRANK BOURNE, Mount Vernon, N. Y., assignor to McElroy-Grunow Electric Railway System, Bridgeport, Conn., a Corporation of New Jersey. Filed Nov. 8, 1901. Serial No. 81,582. (No model.)



Claim.—The described method of operating an electromagnetic switch, consisting in controlling the movements of the movable part thereof by two magnetic forces which act upon magnetically-independent magnetic masses carried by said part and in such manner that when the circuit is first closed they act conjointly and afterward oppose each other.

706,012. **ELECTROMAGNETIC SWITCH.** FRANK BOURNE, Mount Vernon, N. Y., assignor to McElroy-Grunow Electric Railway System, Bridgeport, Conn., a Corporation of New Jersey. Filed Nov. 8, 1901. Serial No. 81,583. (No model.)



Claim.—1. In an electromagnetic switch a fixed and a movable terminal; a movable part carrying the movable terminal provided with two magnetizable parts, together with a magnet-coil adapted to magnetize both of said parts in such manner as to act conjointly to close the switch and ultimately to oppose each other, substantially as described.

2. An electromagnetic switch provided with a terminal operatively connected to a movable part carrying a solenoid-core and an armature; in combination with a fixed terminal and a magnetizing-coil, all relatively so located that when the circuit is closed the core and armature act conjointly to move the terminals into contact with each other and ultimately oppose each other in their pulling effect, substantially as described.

3. In an electromagnetic switch a fixed and a movable terminal and two magnetizable parts carried by the movable part of the switch; a magnetizing-coil adapted to act upon both of said magnetizable parts; in combination with adjustable means for varying the relative effect of the magnetizable parts in such manner that the delicacy of operation of the switch may be varied at will, substantially as described.

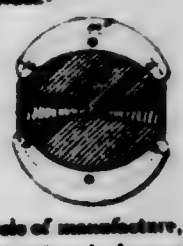
4. An electromagnetic switch embracing a magnet adjustably secured to a base carrying a fixed terminal; a movable part carrying a movable terminal and two magnetizable parts all adapted to be relatively so adjusted with relation to each other and the fixed terminal that on closing the operating-circuit through the coil of the magnet the two magnetizable parts first act conjointly to close the working circuit and afterward

oppose each other in their pull upon the movable part, substantially as described.

5. An electromagnetic switch having a movable terminal and two magnetizable parts, all carried by an insulating-support; in combination with a fixed terminal and a magnetizing-coil, all adjustably secured together and in such manner that on closing the switch-operating circuit both magnetizable parts act first to close the circuit and then oppose each other until the circuit is again broken, substantially as described.

6. An electromagnetic switch having an armature, a solenoid-core and a yielding conducting-terminal all carried by a movable part; in combination with a fixed terminal and an energizing-coil, the arrangement being such that when the circuit is closed through the coil the armature is out of contact with the poles of the magnet and the solenoid-core located with its median line above the median line of the coil, substantially as described.

706,013. ROTARY SCRAPER FOR FINISHING ARTIFICIAL DENTURES. THOMAS J. BOYCE, Chicago, Ill. Filed July 29, 1901. Serial No. 70,067. (No model.)



Claim.—1. As an article of manufacture, a rotary scraper for finishing artificial dentures consisting in a body portion, and a separate curved cutting-surface secured to said body portion and extending toward the axis of the scraper at an end of the same, substantially as described.

2. In a rotary scraper for finishing artificial dentures, the combination with a body portion, of a curved cutting-surface having openings therein into which the body portion extends and thereby securely unites the cutting-surface and body portion, substantially as described.

3. In a rotary scraper for finishing artificial dentures, the combination with a series of curved cutting-blades having openings therein, of a cast-metal body portion partially surrounding said blades and extending through the openings formed therein, substantially as described.

4. In a rotary scraper for finishing artificial dentures, the combination with a series of semicircular cutting-blades, of a body portion in which said blades are partially embedded said body portion having openings formed therein concentrically with the ends of said blades and at opposite points on its circumference, substantially as described.

706,014. COOKING VESSEL. ANTHONY A. BRANDENBURG and WILLIAM C. KNOBLOCH, St. Louis, Mo. Filed Apr. 23, 1902. Serial No. 104,572. (No model.)

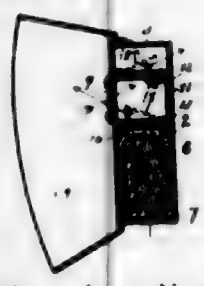
Claim.—1. A cooking vessel having a body portion, an upper outwardly-flaring rim or wall, an annular seat at the base of the rim, a cover having scallops formed along the lower edge thereof adapted to rest on said seat, and means carried by the rim for locking the cover in position, substantially as set forth.

2. A cooking vessel having a body portion, an upper outwardly-flaring rim or wall, a spout having one of its walls formed by the wall of the rim, an annular seat at the base of the rim, a cover having scallops formed along the lower edge thereof adapted to rest on said seat, and means carried by the rim for locking the cover in position, substantially as set forth.

3. A cooking vessel having a body portion, an upper outwardly-flaring rim or wall, a spout, an annular cover adapted to rest within the rim, openings or perforations formed on the cover above the lower edge thereof, recesses having vertical and horizontal members cut in the peripheral wall of the cover, and locking-cams distributed along the inner surface of the rim for engaging said recesses and locking the cover in position, substantially as set forth.

4. A cooking vessel having a body portion, an upper outwardly-flaring rim or wall, an annular seat at the base of the rim, a cover having a series of openings formed adjacent to the lower edge thereof adapted to rest on said seat, and means carried by the rim above said seat for locking the cover in position, substantially as set forth.

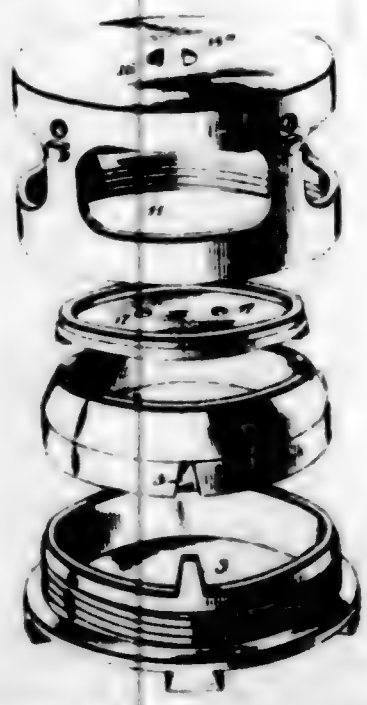
706,015. INHALER. JAMES F. BAKER, Dayton, Ohio. Filed May 12, 1902. Serial No. 106,971. (No model.)



Claim.—1. In an inhaler, the combination with a casing having openings therein for the admission of air from without, a compartment in said casing containing suitable absorbent material through which the said air first passes, of a valve-frame comprising two parallel portions having openings therein, said valve-frame being mounted in said casing, inlet and outlet valves supported on the parallel parts of said valve-frame, said valves consisting of rectangular frames having each an opening therein, and said openings being closed by flaps consisting of any suitable flexible material, one of the longitudinal edges of said flaps being secured to one of the longitudinal edges of said frames, substantially as shown and described.

2. In an inhaler, the combination with a casing having a compartment therein for containing a suitable absorbent body, an opening in the rearward wall of said casing above said compartment, and an opening in said casing below said compartment and through which air is admitted to the absorbent body within said compartment, of a valve-frame comprising two parallel portions 12 and 13 each having an opening, said frame being placed within the casing with the said parallel portions occupying positions above and below the opening in the rear side of said casing, inlet and outlet valves supported on said parallel portions 12 and 13, said inlet and outlet valves each consisting of a metallic frame which rests upon said parallel portions of the frame, and a sheet of flexible material secured to each of said valve-frames and being adapted to be raised by the pressure of the incoming and outgoing air, substantially as specified.

706,016. DENTAL FLASK. FRANK A. BREWER, Jr., and GEORGE W. HARVEY, Watsonville, Cal. Filed Nov. 21, 1901. Serial No. 83,136. (No model.)



Claim.—1. A dental flask comprising a bottom, two rings, one of which is integral with the bottom, and a top, in combination with a cap having a screw-threaded connection with the ring integral with the bottom, for locking the parts of the flask together, substantially as set forth.

2. A dental flask comprising a bottom, two rings and a top, one ring being integral with the bottom and being provided with external screw-threads, in combination with a cap surrounding the top or the upper ring and provided with screw-threads to engage said screw-threaded ring, substantially as set forth.

3. A dental flask comprising a bottom, two rings and a top, one ring being fixed to the bottom and provided with lugs to engage recesses in the other ring, in combination with a screw-threaded cap for clamping the parts together, substantially as set forth.

4. The combination with a dental flask, the bottom of which is provided with lugs, of a spider to engage the said lugs, a screw-cap to clamp the parts of the flask together, and a spanner-wrench to engage the screw-cap, substantially as set forth.

706,017. DYNAMO-ELECTRIC MACHINE. JAMES DUNCK, Berlin, Germany. Filed June 26, 1900. Serial No. 21,071. (No model.)

Claim.—1. In a dynamo-electric machine, the combination of pole-piece and a separable extension therefor, the said extension being magnetized directly by the magnet-winding of the machine, as set forth.

2. In a dynamo-electric machine, the combination of a separable extension for the pole-piece, and means for magnetizing the same directly by the magnet-winding of the machine, substantially as described.

3. In a dynamo-electric machine, the combination with the magnet-frame, of a pole-piece, an extension which forms a portion of said pole-piece, the said extension and pole-piece forming an unbroken magnetic circuit, a magnet-winding carried by the pole-piece, and means for bracing the extension and pole-piece against movement, substantially as described.

4. In a dynamo-electric machine the combination with the pole-piece, of extensions therefor, said extensions being adapted to hold the magnet-windings in position, and braces between said extensions, substantially as described.

5. In a dynamo-electric machine, the combination with the pole-piece, of enlarged extensions therefor, said extensions being adapted to retain the magnet-windings in position, and means for securing said extensions against movement, substantially as described.

6. In a dynamo-electric machine the combination with the pole-piece, of extensions therefor adapted to retain the magnet-windings in position, and means for bracing the extensions against the magnet-frame, substantially as described.

7. In a dynamo-electric machine, the combination with the pole-piece, of a separate extension fitted thereto and in magnetic contact therewith, the said extension constituting a portion of the pole-piece, and a magnet-winding surrounding portions of both pole-piece and extension, substantially as described.

8. In a dynamo-electric machine, the combination with the pole-piece, of an extension therefor, the said extension constituting a portion of the pole-piece, and a section of the extension being separable, substantially as described.

9. In a dynamo-electric machine, the combination with the magnet-frame, of a separable pole-piece having a diagonally-cut end adapted to be fitted to and in magnetic contact with the frame, an extension a section of which is separable upon the other end of the pole-piece, a magnet-winding for said pole-piece, adapted to magnetize both the pole-piece and the extension, and means for bracing the pole-piece in contact with the frame, substantially as described.

10. In a dynamo-electric machine, the combination with the magnet-frame, of pole-pieces having one end diagonally cut and adapted to be fitted to and in magnetic contact with the frame, an extension constituting a portion of the pole-piece at the other end, a section of said extension being separable, magnet-windings upon said pole-pieces, and means for bracing the extensions against each other to hold the poles in contact with the frame, substantially as described.

11. In a dynamo-electric machine, the combination with the pole-piece, of an extension constituting a portion thereof, a section of said extension being separable, and a magnet-winding surrounding said pole-piece, substantially as described.

12. In a dynamo-electric machine, the combination of a pole-piece having a longitudinal recess, an extension for said pole-piece having a portion complementary to said recess, and a magnet-winding surrounding said pole-piece, substantially as described.

13. In a dynamo-electric machine, the combination of a pole-piece having a longitudinal recess with an angular end surface, an extension for said pole-piece having a portion complementary to said recess, and a magnet-winding surrounding said pole-piece, substantially as described.

14. In a dynamo-electric machine, the combination of a pole-piece having a longitudinal recess, an extension for said pole-piece having a portion complementary to said recess, a magnet-winding surrounding the pole-piece, and means for bracing the extension in the pole-piece, substantially as described.

15. In a dynamo-electric machine, the combination with the pole-pieces having recesses therein, of extensions having portions complementary to said recesses, magnet-windings surrounding the pole-pieces, and braces between the oppositely-disposed extensions, substantially as described.

16. In a dynamo-electric machine, the combination with the magnet-frame, of a separate pole-piece adapted to be fitted to and in magnetic contact with the frame and having an extension upon its end, constituting a portion of the pole-piece, a magnet-winding for said pole-piece, and means for bracing the pole-piece in contact with the frame, substantially as described.

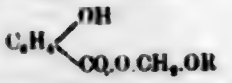
17. In a dynamo-electric machine, the combination of a pole-piece extension separate from the pole-piece, and a magnet-winding surrounding the same, substantially as described.

18. In a dynamo-electric machine, the combination with the pole-piece, of a separate extension therefor having a portion adapted to be fitted to the pole-piece, and a magnet-winding surrounding the said portion of the extension-piece and the pole-piece, substantially as described.

19. In a dynamo-electric machine, the combination with the pole-piece of an extension therefor, a portion of said extension being fitted into and forming part of said pole-piece, a magnet-winding surrounded by said pole-piece and held in position by said extension, and means for bracing the extension against movement, substantially as described.

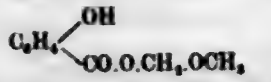
706,018. ALKYLOXYMETHYL ESTER OF SALICYLIC ACID AND PROCESS OF MAKING SAME. JÜRGEN CALLSEN, Elberfeld, Germany, assignor to Farbenfabriken of Elberfeld Co., New York, N. Y., a Corporation of New York. Filed May 7, 1902. Serial No. 106,315. (No specimens.)

Claim.—1. The process for producing the new alkyloxymethylic esters of salicylic acid having the formula:



R meaning an alkyl radical, which process consists in first treating salts of salicylic acid with halogenmethylalkylethers having the above-defined formula: X—CH_2—OR and secondly separating the resulting alkyloxymethylic esters of salicylic acid from the reaction mixture, substantially as hereinbefore described.

2. The process for producing the new methyloxymethylic ester of salicylic acid having the formula:



which process consists in first treating sodium salicylate with monochlordimethylether having the formula: CH_2Cl—O—CH_3 and secondly separating the resulting methyloxymethylic ester of salicylic acid, substantially as hereinbefore described.

3. The herein-described alkyloxymethylic esters of salicylic acid being colorless liquids soluble in ether, alcohol, chloroform and benzene, the alcoholic solutions being colored violet by ferric chlorid and exhibiting valuable therapeutic properties, substantially as hereinbefore described.

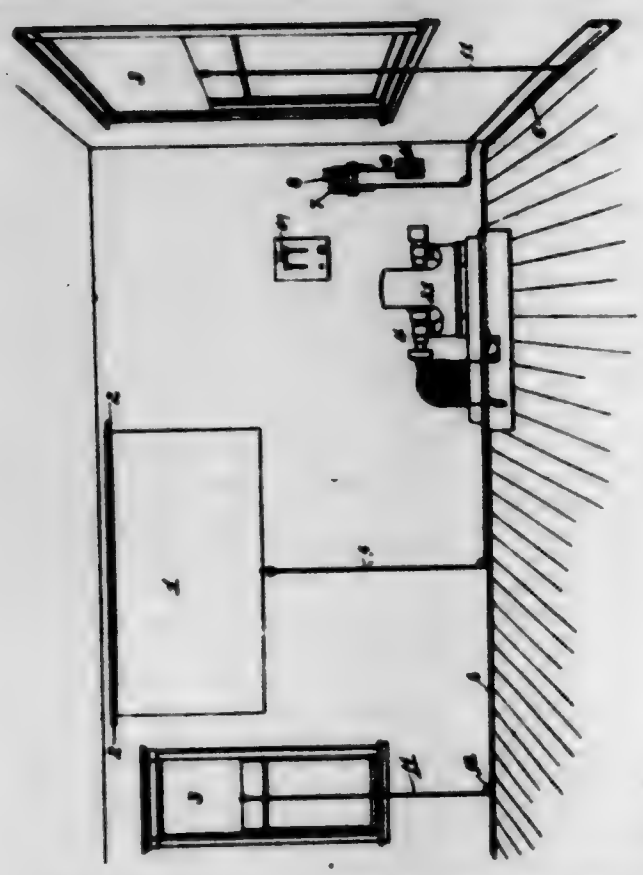
4. The herein-described methyloxymethylic ester of salicylic acid being a clear, colorless liquid boiling at 153° centigrade under a pressure of about thirty-two millimeters, breaking up into salicylic acid, formic aldehyde and methylic alcohol when reacted upon by dilute acids and exhibiting valuable therapeutic properties, substantially as hereinbefore described.

706,019. HOISTING MECHANISM. CHARLES W. CARHART, Chicago, Ill. Filed June 27, 1901. Serial No. 64,264. (No model.)

Claim.—1. In a hoisting system, the combination with a drum having flights of different diameters, of cables having different ranges of travel provided with cords in engagement with the different flights of the drum, a worm-wheel 16 in engagement with the drum, a worm-shaft 17 in engagement with the worm-wheel, a motor, an electromagnetic clutch coupling the motor-shaft with the worm-shaft, switching mechanism for including the helix of the clutch and the motor in circuit, means controlled by the drum for operating this switching mechanism to exclude the motor and the helix of the clutch from circuit, circuit closing and reversing switch mechanism for reversing the direction of rotation of the motor, and connections intervening between the switching mechanisms, whereby the helix of the electromagnetic clutch is included in circuit when the reversing-switch mechanism occupies one or the other of its alternative positions, substantially as described.

2. In a hoisting system, the combination with a drum, of a worm-

wheel 16 in engagement therewith, a worm-shaft 17 in engagement with the worm-wheel, a motor, an electromagnetic clutch coupling the motor-shaft with the worm-shaft, switching mechanism for including the helix of the clutch and the motor in circuit, means controlled by the drum for operating this switching mechanism to exclude the motor and the helix of the clutch from circuit, circuit closing and reversing switch mechanism for reversing the direction of rotation of the motor, and connections intervening between the switching mechanisms, whereby the helix of the electromagnetic clutch is included in circuit when the reversing switch mechanism occupies one or the other of its alternative positions, substantially as described.



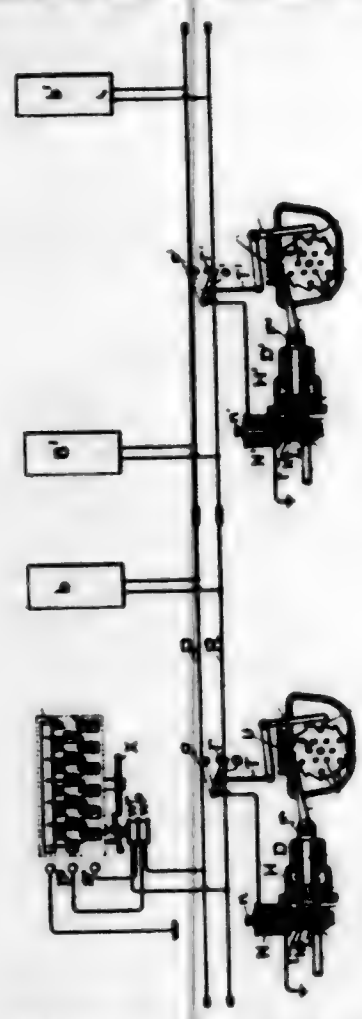
2. In a hoisting system, the combination with a drum having flights of different diameters, of carriers having different ranges of travel provided with cords in engagement with the different flights of the drum, a worm-wheel 16 in engagement with the drum, a worm-shaft 17 in engagement with the worm-wheel, a motor, a clutch coupling the motor-shaft with the worm-shaft, switching mechanism for including the motor in circuit and excluding the same from circuit, means controlled by the drum for operating this switching mechanism and disengaging the clutch members to exclude the motor from circuit and disconnect the same from the drum, and circuit closing and reversing switch mechanism for reversing the direction of rotation of the motor, substantially as described.

4. In a hoisting system, the combination with a drum having flights of different diameters, of carriers having different ranges of travel provided with cords in engagement with the different flights of the drum, a motor having driving connection with the drum, a clutch included in this driving connection, switching mechanism for including the motor in circuit and excluding the same from circuit, means controlled by the drum for operating this switching mechanism and disengaging the clutch members to exclude the motor from circuit and disconnect the same from the drum, and circuit closing and reversing switch mechanism for reversing the direction of rotation of the motor, substantially as described.

5. In a hoisting system, the combination with a drum, of a worm-wheel 16 in engagement therewith, a worm-shaft 17 in engagement with the worm-wheel, a motor, a clutch coupling the motor-shaft with the worm-shaft, switching mechanism for including the motor in circuit and excluding same from circuit, means controlled by the drum for operating this switching mechanism and disengaging the clutch members to exclude the motor from circuit and disconnect the same from the drum, and circuit closing and reversing switch mechanism for reversing the direction of rotation of the motor, substantially as described.

6. In a hoisting system, the combination with a drum, of a motor having driving connection with the drum, a clutch included in this driving connection, switching mechanism for including the motor in circuit and excluding the same from circuit, means controlled by the drum for operating this switching mechanism and disengaging the clutch members to exclude the motor from circuit and disconnect the same from the drum, and circuit closing and reversing switch mechanism for reversing the direction of rotation of the motor, substantially as described.

706,020. TRAIN-CONTROL SYSTEM. FRANK R. GAIL, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Jan. 7, 1901. Serial No. 42,508. (No model.)



Claim.—1. The combination with a plurality of step-by-step controllers, of one or more master-controllers, and means for preventing the further operation of the master-controller in case any controller fails to operate.

2. The combination with a plurality of step-by-step controllers provided with actuating devices, of one or more master-controllers, and independent means associated with the several controllers for rendering inoperative the actuating device of each controller after each actuation thereof.

3. The combination with a plurality of step-by-step controllers provided with electrically-controlled actuating devices, of one or more master-controllers, and means for automatically opening the circuit of each controller-actuating device as soon as the corresponding controller has been operated.

4. The combination with a plurality of step-by-step controllers provided with electrically-controlled actuating devices, of one or more master-controllers, and means for automatically opening the circuit of each controller-actuating device at each step-by-step movement of the corresponding controller.

5. The combination with a plurality of step-by-step controllers provided with electrically-controlled actuating devices, of one or more master-controllers, and an electromagnetic lock for said master-controller in circuit with all of the controller-actuating devices.

6. The combination with a plurality of step-by-step controllers, provided with electrically-controlled actuating devices, of two working conductors, switch-arms automatically operated by the controllers to connect the actuating devices with each conductor alternately, one or more master-controllers, and an electromagnetic lock therefor in circuit with said conductors.

7. The combination with a plurality of step-by-step controllers, provided with electrically-controlled actuating devices, of two working conductors, switch-arms automatically operated by the controllers to connect the actuating devices with each conductor alternately, one or more master-controllers, a helix in circuit with each conductor, and a locking device for the master-controller operated by said helices.

8. The combination with a step-by-step controller, of a wheel carrying two sets of alternating pins, a lever actuated by said pins, a switch-arm connected with the lever, two conductors with which said switch-arm makes connection alternately when actuated, a controller-actuating device in circuit with said switch-arm, and means for energizing said conductors alternately.

9. The combination with two conductors, of a master-controller car-

rying contacts for connecting said conductors alternately with a source of current, a locking device for the controller operated by the current in said conductors, a plurality of controllers provided with electrically-controlled actuating devices, and means for connecting said devices to said conductors alternately.

10. The combination with a plurality of controllers, of separate step-by-step actuating devices for said controllers, an operating system for supplying energy to said actuating devices, and means whereby each controller in operating breaks the connection between its actuating device and the operating system.

11. The combination with one or more controllers, of separate step-by-step actuating devices for said controllers, an operating system comprising a plurality of branches, a master-controller for supplying energy to said actuating devices through either of the branches of the operating system, and means whereby each controller in operating breaks the connection between its actuating device and one of the branches of the operating system and makes a similar connection with another branch of said system.

12. The combination with one or more controllers, of separate step-by-step actuating devices for said controllers, an operating system comprising a plurality of branches, a master-controller for supplying energy to said actuating devices through either of the branches of the operating system, means whereby each controller in operating breaks the connection between its actuating device and one of the branches of the operating system and makes a similar connection with another branch of said system, and means for preventing a movement of the master-controller from one to another of its operative positions until all of the controllers have been similarly operated.

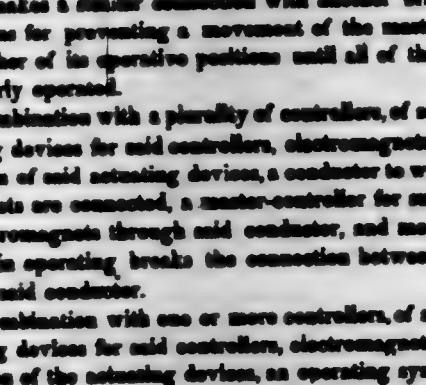
13. The combination with a plurality of controllers, of separate step-by-step actuating devices for said controllers, electromagnets for controlling the operation of said actuating devices, a conductor to which the several electromagnets are connected, a master-controller for supplying current to said electromagnets through said conductor, and means whereby each controller in operating breaks the connection between its electromagnet and the said conductor.

14. The combination with one or more controllers, of separate step-by-step actuating devices for said controllers, electromagnets for controlling the operation of the actuating devices, an operating system comprising a plurality of conductors, a master-controller for supplying current to the said electromagnets through either one of said conductors, and means whereby each controller in operating opens the circuit between its actuating electromagnet and the conductor through which current is being supplied to the same and makes a similar connection between said electromagnet and the other conductor of the operating system.

15. The combination with a plurality of step-by-step controllers, of separate electrically-controlled actuating devices therefor, two working conductors, a master-controller for supplying current to one or the other of said conductors, and means automatically operated by the controllers to connect each of the several actuating devices with the working conductors alternately.

16. The combination with one or more controllers, of separate electrically-controlled actuating devices therefor, two working conductors, a master-controller for supplying current to one or the other of said conductors, and means operated by each of the controllers to shift the connection of the actuating devices from one to the other of the working conductors alternately.

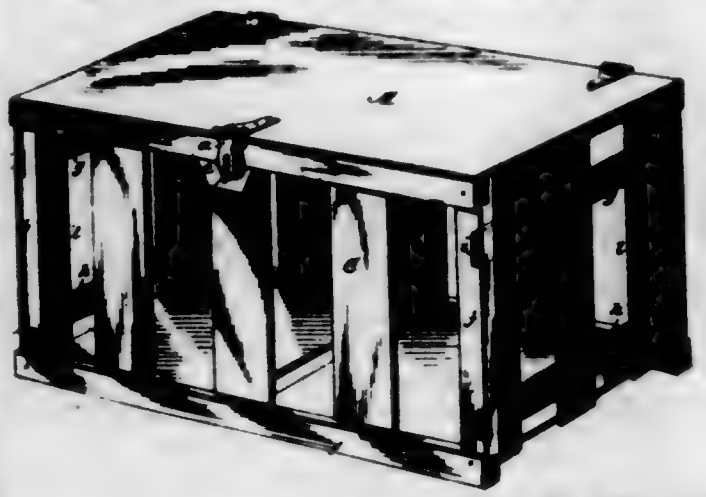
706,021. DEVICE FOR INFLATING PNEUMATIC TIRES. FREDERICK W. CLARKSON and JOHN G. HAGEN, Rochester, N. Y., assignors of one-third to George A. Cheesman, Rochester, N. Y. Filed Feb. 15, 1902. Serial No. 94,269. (No model.)



Claim.—1. In a device for inflating pneumatic tires, an air-bulb having discharge-valve at one end, a head holding the other end and having a chamber with side opening, a stopper having an opening, a cage adjustable in a cavity in said head and having an opening in communication with the side opening of the chamber in the head, and a valve mounted in said cage and fitted to a seat in the bottom of said cavity, all substantially as shown and described.

2. A device for automatically inflating pneumatic tires comprising an air-tube with outlet-valve at one end, a neck at the other end extending substantially at right angles thereto, a stem passed through the rim and engaging the inner wall of the tire and having a thimble for engagement with said neck, a valve in the neck guided in the thimble and fitted to a seat upon its inner end, means on the outer end of the stem for holding the parts together, and a stopper to said stem having an opening, a flange on the inner end of said stem having a vent-opening and valve-seat, a cage in said flange having an opening, and a spring-actuated valve in said cage and fitted to said seat.

706,022. KNOCKDOWN CRATE. HENRY H. CLEMENT, Thomasville, N. C. Filed Feb. 24, 1902. Serial No. 95,201. (No model.)



Claim.—A knockdown crate, comprising two side sections, a top hinged to one of said sections, both sections having longitudinal grooves upon the inner sides of the bottom braces thereof, bottom sections fitting in said grooves, and the upright standards at each end of the side sections having sockets, and end sections with horizontal bars, the projecting ends of which engage the sockets, and the inner upright bars of said end sections abutting against the end upright standards of the side sections to brace the crate at its corners without additional fastenings, substantially as and for the purpose set forth.

706,028. CHURN. ADRIAN CLOSE, Whitehall, Ill. Filed Feb. 17, 1902. Serial No. 94,504. (No model.)

Claim.—The churn herein shown and described, consisting of the rockers, the strips connecting the rockers near their ends, the flat board fitting in the space between the end strips, the pivoted latches carried by the strips and engaging the board to secure the board, the receptacle having weighted handles and mounted on said board and having the bottom walls raised along their center, the guides adjacent to said central raised portion, the dasher having the end pieces fitting in the guides and having the bottom connecting-strip, and the blades secured to the bottom strip and between the said pieces, said blades each composed of a pair of curved plates secured together and arranged in opposite direction.

706,024. SWITCH-OPERATING MECHANISM. GEORGE L. OSGOOD, Bridgeport, Conn., assignor to George P. Carvel, Bridgeport, Conn. Filed Dec. 6, 1901. Serial No. 84,898. (No model.)

Claim.—1. In a switch-operating mechanism in combination, a switch-point, a transversely and vertically movable pin connected with said point, means connected with a car for moving said pin in one direction whereby said switch is thrown and separate means also connected

with a car for moving said pin in the other direction whereby said switch is reset, substantially as described.

2. In a switch-operating mechanism in combination, a switch-point, a transversely and vertically movable pin connected with said point, means connected with a car for moving said pin in one direction whereby said switch is thrown, separate means also connected with a car for moving said pin in the other direction whereby said switch is reset and means for locking said switch-point in its temporary position, substantially as described.

3. In a switch-operating mechanism in combination, a switch-point, yielding means for holding said point in one of its set positions, a transversely and vertically movable pin connected with said point, means connected with a car for moving said pin in one direction whereby said switch is thrown and separate means also connected with a car for moving said pin in the other direction whereby said switch is permitted to return to its normal position.

4. In a switch-operating mechanism in combination, a switch-point, yielding means for holding said point in one of its set positions, means for locking said point in the other of its set positions, a transversely and vertically movable pin connected with said point, means connected with a car for moving said pin in one direction whereby said switch is thrown and separate means also connected with a car for moving said pin in the other direction whereby said locking means are released and said switch permitted to return to its normal position.

5. In a switch-operating mechanism in combination, a switch-point, a case or housing set transversely of said point, an aperture in the top of said case, a block movable longitudinally in said case and connected with said switch-point, a pin vertically movable in said block and projecting through said case-aperture, means for normally holding said switch-point in one of its set positions, means for locking said point in its other set position, means connected with a car for moving said pin transversely whereby said switch is thrown and locked and separate means also connected with said car for depressing said pin whereby said locking means is released and the switch returned to its normal position, substantially as described.

6. In a switch-operating mechanism in combination, a switch-point, a case or housing set transversely of said point, means as a spring for holding said point in its normal position, a block in said case and connected with said point, a pin vertically movable in said block and projecting through an aperture in said case, a second pin movable in said block and adapted to engage with said case when said point has been moved to its temporary position and two separate projecting portions each connected with a car and adapted to move said pin first transversely then vertically whereby said point is thrown, locked, released and reset by the passage of such car, substantially as described.

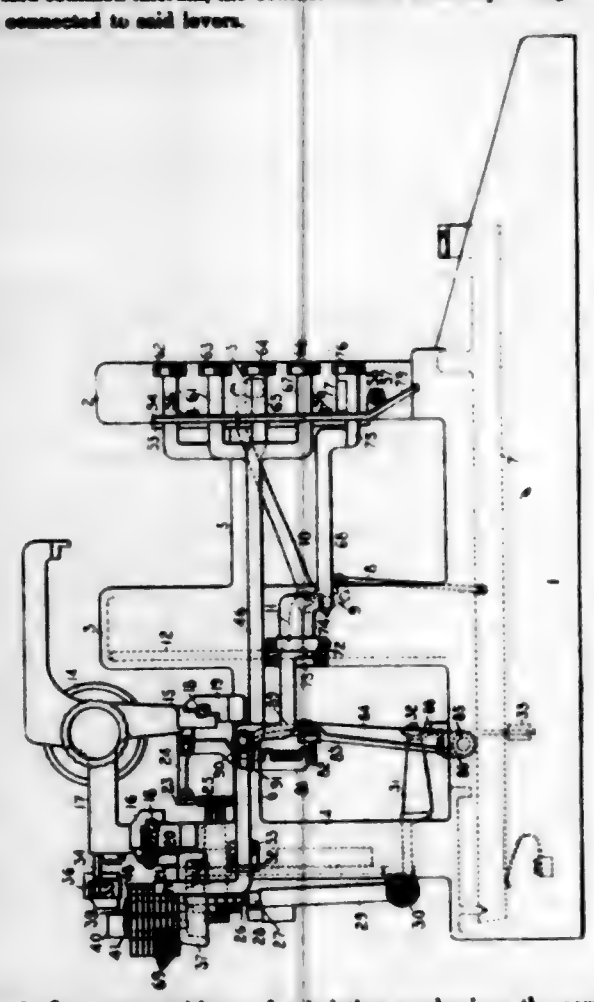
706,025. TYPE-WRITING MACHINE. EDWIN B. CRAM, Brooklyn, N. Y., assignor to Wyckoff, Seamans & Benedict, Ilion, N. Y., a Corporation of New York. Filed June 26, 1901. Serial No. 66,294. (No model.)

Claim.—1. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop upon said carriage, a series of denomination-stop levers pivoted upon the framework and extending longitudinally of the carriage and coöperating with said stop to arrest the latter at variable positions, the contact or stop ends of said levers terminating at letter-space intervals, and keys for swinging said levers and causing their said stops to be projected into the path of travel of the stop on the carriage.

2. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop upon said carriage, a series of denomination-stop levers pivoted upon the framework and extending longitudinally of the carriage and mounted upon a common fulcrum which is arranged transversely of the run of the carriage, one set of the ends of said levers overlapping and terminating at letter-space intervals and being adapted to coöperate with said stop for variably arresting the carriage, and a series of keys mounted in the framework and adapted to act on the other set of the ends of said denomination-stop levers.

3. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop upon said carriage, a series of levers pivoted upon the framework and extending longitudinally of the carriage, a series of projecting stops formed upon the ends of said levers and arranged at letter-space intervals, a carriage-release mechanism, and keys connected to said levers and also to said carriage-release mechanism.

4. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of levers of graduated lengths working upon a common fulcrum and arranged side to side, stops projecting from the ends of said levers in a direction parallel with said common fulcrum, the contact ends of said stops being flush, and keys connected to said levers.



5. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a bank of levers, a support therefor, a common vertical fulcrum for said levers, stops formed upon the ends of said levers and arranged at letter-space intervals, the stops being of graduated lengths according to the elevations of their several levers, and the latter being of graduated lengths according to the locations of their several stops, and means for swinging said levers so as to enable said stops to coöperate with the first-mentioned stop for arresting the carriage.

6. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of levers pivoted between their ends upon a common fulcrum, stops formed upon one set of the ends of said levers and projecting in a direction parallel to said fulcrum, and key connections attached to the other set of lever ends, the levers being of graduated lengths, and the stops being also of graduated lengths and being flush at their contact ends, the shortest lever having the shortest stop and its key connection being the nearest to said fulcrum, the longest lever having the longest stop and its key connection being the most remote from said fulcrum, and the intermediate levers having the intermediate stops and intermediate connections.

7. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop upon the carriage, a series of levers supported upon the framework at the rear of the carriage and extending longitudinally of the latter, said levers having stops arranged at letter-space intervals along the run of the carriage, and connections extending from said levers forwardly to the keyboard of the machine, said connections bearing keys at their forward ends.

8. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a rack arranged upon the carriage, a column-stop adjustable along said rack, and a series of key-operated stop-levers mounted upon the frame and arranged longitudinally of said rack, said stop-levers terminating successively at letter-space intervals along said rack so as to arrest the carriage variably according to the lever operated.

9. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a rack arranged upon the carriage, a column-stop adjustable along said rack, and a series of key-operated stop-levers mounted upon the frame and arranged longitudinally of said rack, said stop-levers terminating successively at letter-space intervals along said rack, so as to arrest the carriage variably according to the lever operated, said levers being of graduated length and mounted side to side upon an axis or fulcrum which extends transversely of the rack.

10. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a rack arranged upon the carriage, a column-stop adjustable along said rack, and a series of key-

operated step-levers mounted upon the frame and arranged longitudinally of said rank, said step-levers terminating successively at letter-space intervals along said rank, so as to arrest the carriage variably according to the lever operated, and also vibrating in horizontal planes and being connected by endwise-movable forwardly-extending rods to keys arranged at the keyboard of the machine.

11. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a rank arranged upon the carriage, a column-stop adjustable along said rank, and a series of key-operated step-levers mounted upon the frame and extending from a common vertical fulcrum or pivot in a direction opposite to the advance movement of the carriage and being provided with vertically-projecting stops of graduated lengths and arranged at letter-space intervals, said stops being moved sidewise by the levers into position for engaging said column-stop.

12. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop upon the carriage, a series of vertical stops arranged at letter-space intervals upon the frame-work, a series of levers banked one upon another and working upon a common vertical axis which is arranged between the ends of the levers, and keys connected to the ends of said levers opposite to the stops.

13. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a column-stop rank mounted upon the rear portion of the carriage, a series of levers banked upon the top plate of the machine and working upon a common vertical fulcrum and having formed upon one set of their ends a series of projecting stops, rods extending forwardly from the other set of lever ends to the front of the machine, and keys mounted upon the forward ends of said rods.

14. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a column-stop rank mounted upon the rear portion of the carriage, a series of levers banked upon the top plate of the machine and working upon a common vertical fulcrum and having formed upon one set of their ends a series of projecting stops, rods extending forwardly from the other set of lever ends to the front of the machine, and keys mounted upon the forward ends of said rods, the key ends of said rods diverging, the keys being arranged in a downwardly-extending row at the side of the machine.

15. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop upon the carriage, a series of levers 38 banked upon the framework and extending longitudinally of the carriage, a common vertical fulcrum 39 for said levers, a series of coincident slots 42 formed on said levers, a common stop 41 passing through said slots, springs 43 bearing against said levers, push-rods 46 engaging said levers and extending forwardly therefrom, and keys carried by the forward ends of said push-rods.

16. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop upon the carriage, a series of levers 38 banked upon the framework and extending longitudinally of the carriage, a common vertical fulcrum 39 for said levers, springs 43 bearing against said levers, and key-bearing rods 46 engaging said levers and extending forwardly therefrom, said rods having upwardly-projecting fingers 48 which engage eyes formed in said levers, and the latter having cut-aways 52.

17. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a column-stop upon the carriage, a series of levers working upon a common vertical axis and extending longitudinally of the carriage and having at their inner ends a series of denomination-stops arranged at letter-space intervals, and a series of forwardly-extending rods having at their rear ends upwardly-extending devices engaged to the outer ends of said levers, said rods diverging at their forward ends and bearing keys.

18. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a column-stop upon the carriage, a series of levers working upon a common vertical axis and extending longitudinally of the carriage and having at their rear ends a series of denomination-stops arranged at letter-space intervals, a series of forwardly-extending rods having at their rear ends upwardly-extending devices engaged to the outer ends of said levers, a bracket 32 for the rear ends of said rods, differently-offset key-bearing stems on the forward ends of said rods, and a bracket for guiding said offset stems.

19. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a column-stop upon the carriage, a series of levers of graduated lengths working upon a common vertical axis and extending longitudinally of the carriage and having at their inner ends a series of denomination-stops arranged at letter-space intervals, a series of forwardly-extending rods having at their rear ends upwardly-extending devices engaged to the outer ends of said levers, said rods being disposed side by side and having at their forward ends upwardly and downwardly offset key-stems, and means for guiding said rods.

20. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a column-stop upon the carriage, a series of levers banked one upon another and working upon a common fulcrum and extending longitudinally of the carriage and having at their inner ends a series of denomination-stops arranged at letter-space intervals, said stops being of graduated heights and terminating upon the same level, a series of rods having at their rear ends a series of upwardly-extending devices of graduated lengths engaged to the outer ends of said levers, and keys connected to the forward ends of said rods.

21. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a column-stop upon the carriage, a series of levers banked one above another and working upon a common fulcrum and extending longitudinally of the carriage and having at their inner ends a series of denomination-stops arranged at letter-space intervals, said stops being of graduated heights and terminating at the same level, a series of rods having at their inner ends upwardly-extending devices of graduated lengths engaged to the outer ends of said levers, and keys connected to the forward ends of said rods, the longest of said levers lying at the bottom and having the longest stop and being connected to the outermost rod, and the shortest lever lying at the top and having the shortest stop and being connected to the innermost rod, and cut-aways formed in the outer ends of said levers so as to permit independent movement thereof by said rods.

22. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a group of denomination-stops coöperating therewith, a selecting-key, and means for enabling said key to operate any of said denomination-stops independently of the remaining denomination-stops.

23. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops coöperating therewith, a series of denomination-stop levers, a selecting-key, and means for enabling said key to operate any of said levers independently of the remaining levers.

24. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a column-stop adjustable along the carriage, a series of denomination-stops arranged side by side at letter-space intervals, levers upon which said denomination-stops are mounted, and a selecting-key having means for engaging any of said levers.

25. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops coöperating therewith, a key, and means for enabling said key when moved in one direction to select any of said stops and when moved in another direction to set the selected stop.

26. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop and a denomination-determining mechanism, the latter including a series of levers connected to means for variably arresting the carriage, and also including means for enabling said key to select any of said levers and then to operate or set the selected lever independently of the other levers.

27. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of levers having ends formed and arranged for coöperation with said stop to variably arrest the carriage, a key, and means for enabling said key to select any of said levers and then set the selected lever.

28. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of levers arranged side to side and having a common fulcrum, said levers having ends formed and arranged for coöperation with said stop to variably arrest the carriage, a key, and means for enabling said key to select any of said levers and then set the selected lever.

29. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of levers extending longitudinally of the carriage, steps projecting from their ends and coöperating with the first-mentioned stop to variably arrest the carriage, a key, and means for enabling said key to select any of said levers and then set the selected lever.

30. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops for coöperation therewith, and a rod mounted for movement in transverse directions, said rod moving in one direction for selecting a stop and moving in another direction for operating said stop.

31. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of independently-movable denomination-stops for coöperation therewith, and a key-rod having a transverse stop-selecting movement and a longitudinal stop-setting movement.

32. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of independently-movable step-levers, and a rod movable from one lever to another and adapted to vibrate any of said levers.

33. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops, and an endwise-movable swiveled rod for selecting and setting the stops.

34. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of levers pivoted between their ends and having means at one set of their ends for variably arresting the carriage, and a rod for engaging any of the levers at the other set of their ends and adapted to vibrate the engaged lever upon its pivot.

35. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of levers pivoted between their ends and formed and arranged at one set of their ends for variably arresting the carriage, notches 70 in said levers, and an endwise-movable rod swiveled between its ends and having a part adapted to engage any of said notches 70 and swing the engaged lever upon its pivot.

36. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of levers pivoted between their ends, a series of denomination-stops upon said levers, notches 70 and cut-aways 92 upon said levers, and an endwise-movable swiveled rod having an arm or finger adapted to engage any of said notches 70 and swing the engaged lever upon its pivot.

37. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of levers extending longitudinally of the carriage and having projecting stops adapted for coöperation with the carriage-stop, a common fulcrum for said levers, fingers 69 formed upon the ends of said levers opposite said stops, rod 68 having an arm or finger 71 for engaging any of said fingers 69, swiveling device 72 for said rod, and key 76.

38. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops coöperating therewith, a selecting-key, means for enabling said key to operate any of said denomination-stops independently of the remaining denomination-stops, and a denomination-indicator for said key.

39. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops for coöperation therewith, a series of denomination-stop levers, a selecting-key, means for enabling said key to operate any of said levers, and a plate arranged at said key and marked to indicate the denominations corresponding to the several stop-levers.

40. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops coöperating therewith, a key, means for enabling said key when moved in one direction to select any of said stops and when moved in another direction to set the selected stop, and means arranged at the key for guiding the latter during the stop-setting movement thereof.

41. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops coöperating therewith, a selecting-key, means for enabling said key to operate any of said denomination-stops independently of the remaining denomination-stops, a denomination-indicator for said key, and means arranged at said key for guiding the latter during the stop-setting movement thereof.

42. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops coöperating therewith, a key-rod movable transversely for selecting any of said stops and also movable longitudinally for operating the selected stop, and a series of guiding-slots for said rod.

43. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops coöperating therewith, a key-rod movable transversely for selecting any of said stops and also movable longitudinally for operating the selected stop, a series of guiding-slots for said rod, and a denomination-indicator.

44. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a set of denomination-stops, and a set of keys therefor, the number of keys being less than the number of the denomination-stops, one of said keys having means for projecting a plurality of said stops, and the other keys being connected each to a single stop.

45. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a set of denomination-stops, and a set of keys, the number of keys being less than the number of the denomination-stops, and at least one of the keys having means for setting a plurality of the denomination-stops.

46. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of coöperating stop members, and stop-setting devices controlled by a plurality of denomination-keys, at least one of said keys controlling means for causing the arrest of the carriage at a plurality of denominational positions.

47. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops coöperating therewith, a series of denomination-stop levers, a selecting-key having means for operating some of said levers, and keys connected one to each of the remaining levers.

48. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops coöperating therewith, a series of keys, the number of said keys being less than the number of said denomination-stops, means for enabling at least one of said keys when moved in one direction to select one of several denomination-stops and when moved in another direction to set the selected stop, and means for enabling the other keys to operate the other denomination-stops.

49. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of independently-movable denomination-stops for coöperation therewith, a key-rod having a transverse stop-selecting movement and a longitudinal stop-setting movement, whereby it may operate several of said denomination-stops, and a series of key-rods having longitudinal stop-setting movements and connected one to each of the remaining denomination-stops.

50. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of independently-movable stop-levers, and a series of rods, said rods being fewer in number than said levers, and at least one of said rods being movable from one lever to another and adapted to vibrate the selected lever.

51. In a type-writing and tabulating mechanism, the combination with a carriage and carriage-feeding devices, of a stop, a series of denomination-stops, an endwise-movable swiveled rod for selecting and setting several of the denomination-stops, and endwise-movable rods connected one to each of the remaining stops.

52. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop, a series of denomination-stop levers, a series of key-rods connected to said levers, and a carriage-releasing device having a part which extends transversely of said rods so as to be engaged thereby.

53. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a rack arranged upon the carriage, a column-stop adjustable along said rack, a series of key-operated stop-levers mounted upon the frame and arranged longitudinally of said rack, said stop-levers terminating successively at letter-space intervals along said rack so as to arrest the carriage variably according to the lever operated, and also vibrating in horizontal planes and being connected by endwise-movable forwardly-extending rods to keys arranged at the keyboard of the machine, and carriage-releasing devices including a part extending across said rods and engageable thereby.

54. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop, a series of denomination-stops coöperating therewith, a selecting-key, means for enabling said key to operate any of said denomination-stops independently of the remaining denomination-stops, and a carriage-releasing device operated by said key.

55. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop, a series of denomination-stops coöperating therewith, a series of denomination-stop levers, a selecting-key, means for enabling said key to operate any of said levers independently of the remaining levers, and a carriage-releasing device operated by said key.

56. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop, a series of denomination-stops coöperating therewith, a key, means for enabling said key when moved in one direction to select any of said stops and when moved in another direction to set the selected stop, and a carriage-releasing device operated by the stop-setting movement of said key.

57. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop, a denomination-determining mechanism, the latter including a series of levers connected to means for variably arresting the carriage, and also including means for enabling said key to select any of said levers and then to operate or set the selected lever independently of the other levers, and a carriage-releasing device operated by the lever-setting movement of said key.

58. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop, a series of denomination-stops for coöperation therewith, a rod mounted for movement in transverse directions, said rod moving in one direction for selecting a stop and moving in another direction for operating said stop, and a carriage-releasing device engaged by said rod at the stop-setting movement thereof.

50. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop, a series of independently-movable denomination-stops for coöperation therewith, a key-rod having a transverse stop-selecting movement and a longitudinally stop-setting movement, and a carriage-releasing device engaged by said rod at the longitudinal movement thereof.

60. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop, a series of independently-movable stop-levers, a rod movable from one lever to another and adapted to vibrate any of said levers, and a carriage-releasing device engaged by said rod at the lever-vibrating movement thereof.

61. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop, a series of denomination-stops, an endwise-movable swiveled rod for selecting and setting the stops, and a carriage-releasing device operable by said rod.

62. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop, a set of denomination-stops, a set of keys, the number of keys being less than the number of the denomination stops and at least one of the keys having means for setting a plurality of the denomination-stops, and a carriage-releasing device operable by all of said keys.

63. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of coöperating stop members, stop-setting devices controlled by a plurality of denomination-keys, at least one of said keys controlling means for causing the arrest of the carriage in a plurality of denominational positions, and a carriage-releasing device operable by all of said keys.

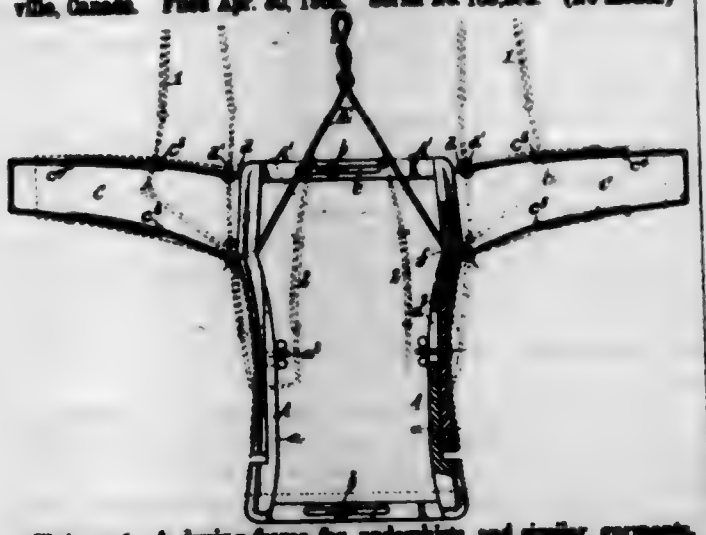
64. In a type-writing and tabulating mechanism, the combination with a power-driven carriage and carriage-feeding devices, of a stop, a series of independently-movable denomination-stops for coöperation therewith, a key-rod having a transverse stop-selecting movement and a longitudinal stop-setting movement, whereby it may operate several of said denomination-stops, a series of key-rods having longitudinal stop-setting movements and connected one to each of the remaining denomination-stops, and a carriage-releasing device operable by all of said rods.

65. In a type-writing and tabulating mechanism, the combination with a power-driven carriage, of a carriage-feed-rack frame, escapement devices connected thereto, arm 81 upon said frame, bar 83 extending longitudinally of the carriage and adapted to engage said arm, a stop for said carriage, a denomination-determining mechanism, and means operated by said denomination-determining mechanism for moving said bar 83 and causing it to engage the arm 81 and release the carriage-feed rack.

66. In a type-writing and tabulating mechanism, the combination with a power-driven carriage, of a carriage-feed-rack frame, escapement devices connected thereto, arm 81 upon said frame, bar 83 extending longitudinally of the carriage and adapted to engage said arm, rocker-arms 84 carrying said bar 83, pin 90 connected to said bar, a stop for said carriage, and a denomination-determining mechanism, including means for moving said pin 90 and causing the bar 83 to engage the arm 81 and release the carriage-feed rack.

67. In a type-writing and tabulating mechanism, the combination with a power-driven carriage, of a carriage-feed-rack frame, escapement devices connected thereto, arm 81 upon said frame, bar 83 extending longitudinally of the carriage and adapted to engage said arm, a column-stop adjustable along the carriage, a set of denomination-stop levers, key-rods for operating said levers, and means for enabling said key-rods to operate said bar 83.

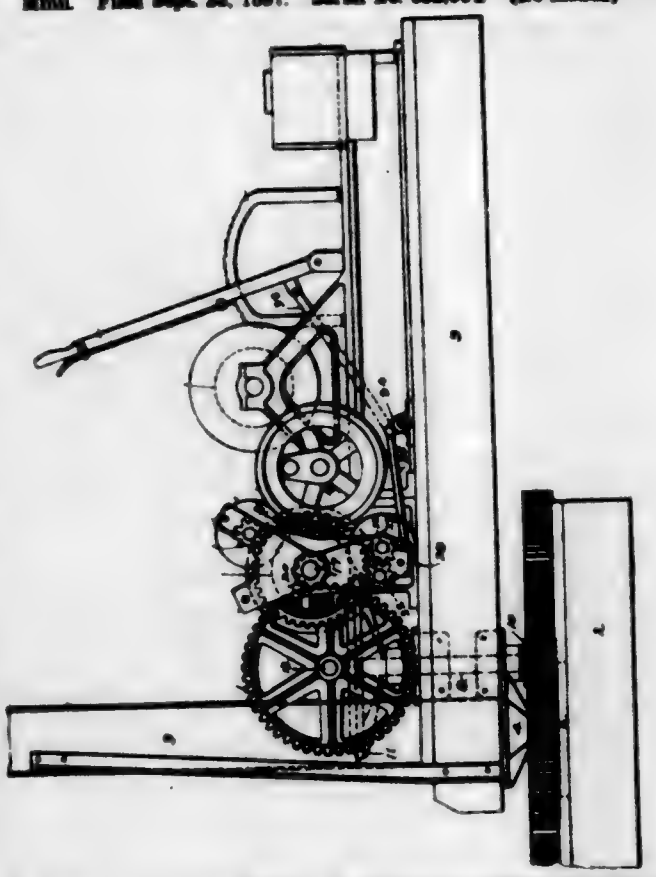
706,026. **GARMENT-STRETCHER.** FRANCIS F. CRAWFORD, Dunnville, Canada. Filed Apr. 30, 1902. Serial No. 105,292. (No model.)



Claim.—1. A drying-frame for undershirts and similar garments, consisting of a body portion conforming approximately to the body of the garment, foldable arm members having upper and lower rods or bars, one of which is pivoted to said body portion, and a suspension-cord connected with the other rod of the arm member and arranged to hold the same in position against the body portion of the frame, substantially as set forth.

2. A drying-frame for undershirts and similar garments, consisting of a body portion conforming approximately to the body of the garment and having its side bars provided with guide-openings, foldable arm-members each having an upper rod or bar pivoted at its inner end to said body portion and a lower rod or bar connected with said upper rod but detached from said body portion, and a suspension-cord connected with the lower detached rods of the arm members and passing through said guide-openings, substantially as set forth.

706,027. **REVERSING MECHANISM.** OLIVER CROSBY, St. Paul, Minn. Filed Sept. 22, 1897. Serial No. 652,634. (No model.)



Claim.—1. In combination the driven and driving parts, the interposed oscillating frame having radial arms, a pair of friction-wheels carried one by each of said arms, pinions carried by said friction-wheels and a gear arranged between said pinions, as and for the purpose set forth.

2. In combination, the driven and driving parts, an interposed frame adapted to oscillate upon a central shaft, friction-wheels mounted on the opposite ends of said frame, and adapted to be engaged by the driving part, a gear loosely mounted on said shaft, a pinion actuated by one of said friction-wheels and intermeshing with said gear, and a pair of pinions actuated by the other friction-wheels and similarly engaging with said gear, and an operative connection between said gear and the part to be driven.

706,028. **PEDAL FOR BICYCLES.** FRANCIS H. CULLEN, Toronto, Canada. Filed Apr. 29, 1901. Serial No. 56,081. (No model.)

Claim.—1. In a bicycle-pedal, a hub adapted to be connected to the pedal-crank, a footbold foldably connected to the hub, and a brace, one end of which is rigidly connected to the footbold and the other end of which engages the hub and supports the footbold in the folded and extended positions, substantially as specified.

2. In a bicycle-pedal, a hub adapted to be connected to the pedal-crank and provided with a transversely-disposed groove, a footheld foldably connected to the hub and a brace, one end of which is connected to the footheld and the other end of which is adapted to register in the groove formed in the hub, substantially as specified.

3. In a bicycle-pedal, a hub adapted to be connected to the pedal-crank, a footheld foldably connected to the hub, a cam for the hub adjacent to the footheld a brace one end of which is connected to the footheld and the other end of which abuts against the hub when the footheld is in its extended position to firmly brace the same and engages the cam when the footheld is in its folded position, substantially as specified.

4. In a bicycle-pedal, a hub adapted to be connected to the pedal-crank and provided with downwardly-directed lugs, a footheld foldably connected to the hub, a brace, one end of which is rigidly connected to the footheld, and the other end of which engages the hub to support the footheld in its extended position, substantially as specified.

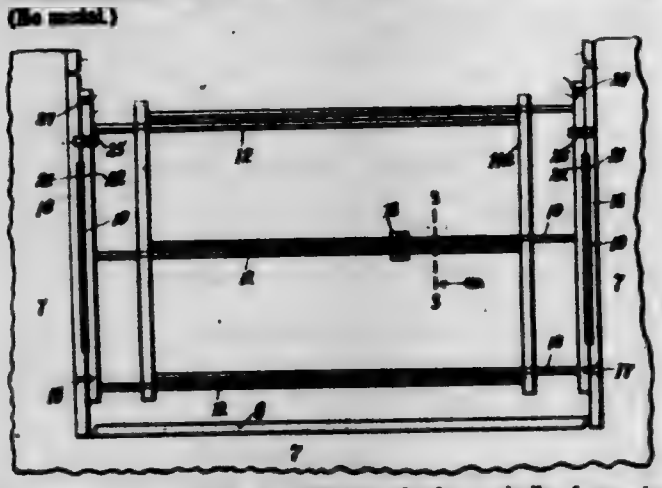
5. In a bicycle-pedal, a hub adapted to be connected to the pedal-crank and provided with downwardly-directed lugs, a footheld foldably connected to the hub, a brace, one end of which is rigidly connected to the footheld and the other end of which is free to engage the lugs of the hub when the footheld is in its extended position, cams on the lugs to distend the brace to hold the footheld firmly in its folded position, substantially as specified.

6. In a bicycle-pedal, a hub, a footheld foldably connected to the hub, downwardly-directed lugs integrally formed with the hub, a brace for the footheld one end of which is rigidly connected to the footheld and the other end of which is adapted to engage the lugs, and a tongue for the brace to register between the lugs, substantially as specified.

7. In a bicycle-pedal, a hub, downwardly-directed lugs integrally formed with the hub, a footheld foldably connected to the hub, a groove in the side face of the lugs adjacent to the footheld, a brace one end of which is rigidly connected to the footheld and the other end of which is free to engage the lugs and register in the groove when the footheld is in its extended position, and a tongue on the free end of the brace to register between the lugs, substantially as specified.

8. In a bicycle-pedal, a hub, downwardly-directed lugs integrally formed with the hub, a footheld foldably connected to the hub, a groove in the side face of the lugs adjacent to the footheld, a brace, one end of which is rigidly connected to the footheld and the other end of which is free to engage the lugs and register in the groove when the footheld is in its extended position, a tongue on the free end of the brace to register between the lugs, and cams on the lugs to distend the brace to securely hold the footheld in its folded position, substantially as specified.

706,029. WINDOW-GUARD. HARMON P. CULVER and HOMER LIGHTENTAFF, New York, N.Y. Filed Oct. 10, 1901. Serial No. 78,149. (No model.)

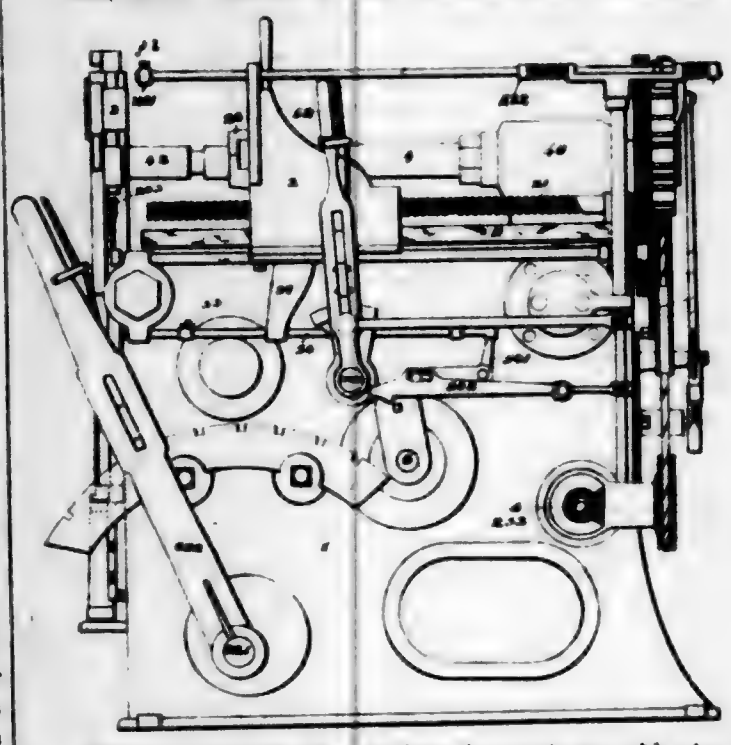


Claim.—1. A window-guard composed of two similar frames longitudinally adjustable and each of which is provided at its outer end with a supplemental bar to which it is pivoted near the lower end thereof, and side links pivotally connected with the outer ends of each frame at or near the top thereof, and two said supplemental bars at or near the top thereof, said links being pivotally connected substantially as shown and described.

2. A window-guard, composed of two similar frames longitudinally adjustable and each of which is provided at its outer end with a supplemental bar to which it is pivoted near the lower end thereof, and side links pivotally connected with the outer ends of each frame at or near the top thereof, and to the supplemental bars at or near the top thereof, said links being pivotally connected and means for holding the guard within the supplemental bars, substantially as shown and described.

3. A window-guard comprising two separate similar open frames each of which consists of two vertically-arranged end pieces and a plurality of horizontal rods, the rods of each frame being passed through one end piece of the other frame, supplemental bars to which the guard is pivoted at or near the bottom thereof, and devices for holding the guard in an upright position between the supplemental bars and other devices for lowering said guard outwardly and holding it in a horizontal position.

706,080. METAL-CRIMPING MACHINE. GEORGE CUSIN, Montreal, Canada. Filed Oct. 24, 1900. Serial No. 34,205. (No model.)



Claim.—1. In a pipe-elbow machine, the combination with crimping mechanism and creasing mechanism, and a cam-wheel geared to the power-shaft within the machine-frame and operatively connected by means adapted to crimp and crease alternately, as described.

2. In a pipe-elbow machine, the combination with crimping mechanism and creasing and folding mechanism, and a rotating oval cam adapted to actuate each mechanism alternately, a face-plate pivotally supported on the edge of the frame, and means for tilting the face-plate, as described.

3. In a pipe-elbow machine, the combination with crimping mechanism and creasing and folding mechanism, and a tilting face-plate provided with a supporting-collar, and means for tilting same, as described.

4. In a pipe-elbow machine, the combination with crimping mechanism and creasing and folding mechanism, and a sliding collar supported on a tilting face-plate, and means to open and close collar upon pipe.

5. In a pipe-elbow machine, the combination with crimping mechanism and creasing and folding mechanism, a tilting face-plate and means for tilting same, and a sliding collar supported on face-plate and means to open and close collar, as described.

6. In a pipe-elbow machine, the combination with a tilting face-plate, of a reciprocating frame with crimping-jaws attached thereto, and a sliding collar, as described.

7. In a pipe-elbow machine, a feed mechanism comprising a carriage provided with a pipe-clamp traveling on two screws, each having a pinion meshing with a gear-wheel, and means to rotate the gear-wheel, as described.

8. In a pipe-elbow machine, the combination of a hollow stationary mandrel, with a reciprocating rod therein, a slotted sleeve on the end of the mandrel, a movable head pivotally supported on the outer end of the sleeve and operatively connected with the rod, and a forked bell-crank lever in sliding contact with a cam mounted on a counter-shaft beneath the mandrel, as described.

9. In a pipe-elbow machine, a stationary hollow mandrel, having a slotted sleeve, a headpiece thereto having a projecting shoulder, a movable headpiece having bearings on the sleeve, and means to reciprocate the sleeve and operate the movable headpiece, as described.

10. In a pipe-elbow machine, a stationary hollow mandrel having a slotted sleeve, a headpiece thereto having a projecting shoulder, a movable headpiece having bearings on the sleeve, and means to reciprocate the sleeve and operate the movable headpiece, a loose pin in head piece and a reciprocating rod with projections adapted to operate the movable head as described.

11. In a pipe-elbow machine, the combination with crimping mechanism of an actuating-lever provided with eccentric bearings adapted to adjust the stroke of the crimping-jaws, as described.

12. In a pipe-elbow machine, the combination of a feed-carriage provided with a pipe-clamp, and screw-threaded bearings, two parallel screws adapted to operate feed-carriage with pinions thereto, a gear-wheel mesh-

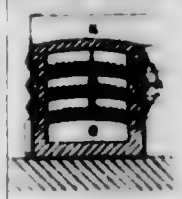
ing with the pinions and means to rotate the gear-wheel intermittently when feeding, and continuously when returning feed-carriage, as described.

13. In a pipe-elbow machine, a stopping and starting mechanism consisting of a rod reciprocated by feed-carriage by means of stops, and means of connecting and disconnecting feed gear-wheel with feed-operating mechanism, as described.

14. In a pipe-elbow machine, the combination of a feed-carriage provided with a pipe-clamp traveling on two screws, each having a pinion meshing with a gear-wheel and means to vary the amount of rotation of the gear-wheel, as described.

15. In a pipe-elbow machine, a reciprocating sleeve provided with a projecting shoulder curved to support the uncrimped portion of the pipe-bend beyond the movable head of the creasing mechanism.

706,081. FURNACE FOR ANNEALING WIRE. FRED H. DANIELS, Worcester, Mass. Filed Apr. 9, 1902. Serial No. 101,891. (No model.)



Claim.—1. In a wire-annealing furnace, a chamber through which the wire is drawn, said chamber having a floor adapted to support the wire, said floor being constructed of tiles having longitudinal corrugations formed therein to constitute channels or gutters to separate and guide the plies of the wire.

2. In a wire-annealing furnace, a chamber through which the wire is drawn, said chamber having a floor adapted to support the wire, and having longitudinal corrugations to form channels or gutters to separate and guide the plies of the wire, said floor having also similar corrugations on its under side alternating in position with those on the upper side.

3. In a wire-annealing furnace having a plurality of superposed chambers through which the wire is drawn consecutively, said chambers having floors formed of longitudinally-corrugated tiles to form channels or gutters to separate and guide the plies of the wire, and the under sides of the tiles having similar corrugations to form collectors for the heat in the chamber below.

4. In a wire-annealing furnace having a fire-box in stack, the combination with a chamber or chambers through which the products of combustion pass and through which the wire is drawn in direct contact with said products, of a floor adapted to support the wire and having open longitudinal channels or gutters to separate and guide the plies of the wire, and means for maintaining a pressure in said chambers above that of the atmosphere, said means consisting of a blast of air or steam in the ash-pit of the furnace.

706,082. HEATING-FURNACE. FRED H. DANIELS, Worcester, Mass. Filed May 2, 1902. Serial No. 105,671. (No model.)

Claim.—1. A furnace of the continuous type, comprising a hot-billet section, and a relatively long cold-billet section continuing beyond the hot-billet section, said hot-billet section opening into the continuation of the cold-billet section, whereby the waste gases of the hot-billet section are diverted into said continuation of the cold-billet section, and means for charging each section.

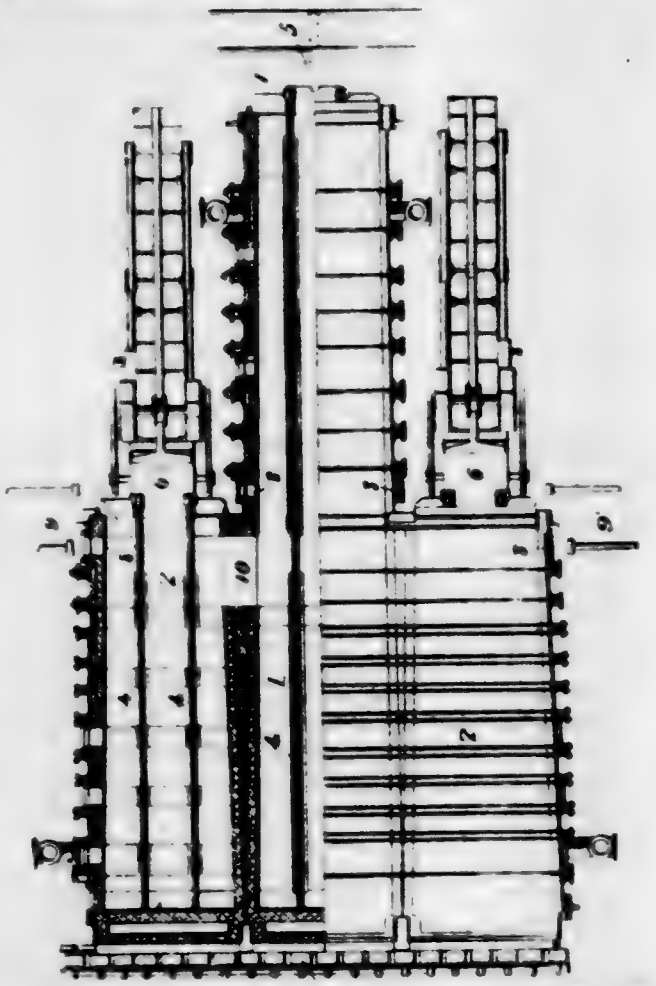
2. A furnace of the continuous type, comprising a hot-billet section and a relatively long cold-billet section, means for charging each section, and means for transferring billets from the cold-billet section into the hot-billet section.

3. A furnace of the continuous type, comprising a hot-billet section and a relatively long cold-billet section, said hot-billet section opening into the cold-billet section, whereby the waste gases of the hot-billet section are diverted into the cold-billet section, and means for transferring billets from the cold-billet section into the hot-billet section.

4. A furnace of the continuous type, comprising a hot-billet section, and a relatively long cold-billet section continuing beyond the hot-billet section, said sections being separated by a wall having an opening near the charging end of the hot-billet section through which the waste gases of the hot-billet section are diverted into the continuation of cold-billet section.

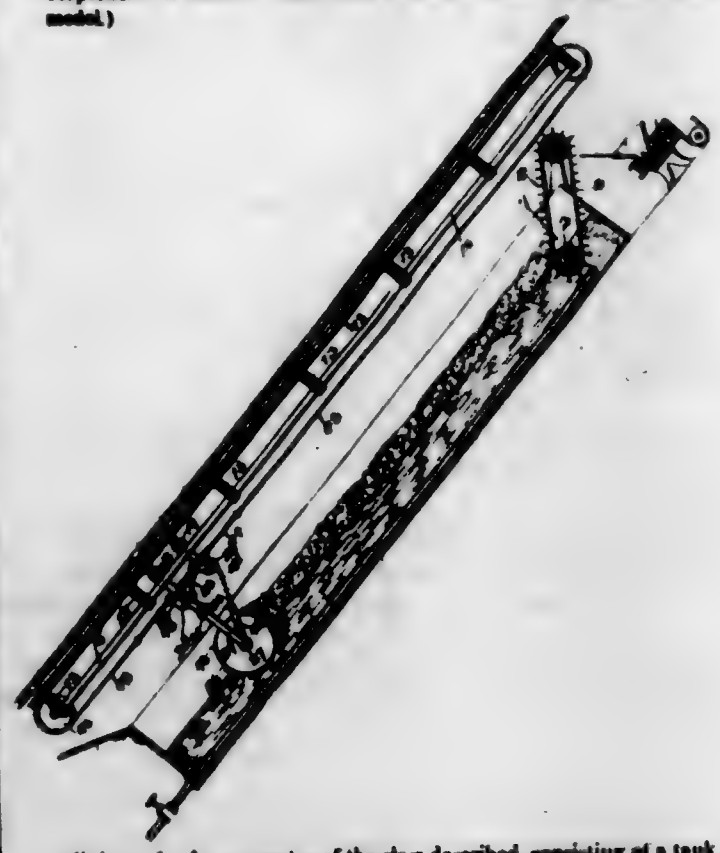
5. A furnace of the continuous type, comprising a cold-billet section and relatively short hot-billet sections located on each side of said cold-billet section, said hot-billet sections communicating with the cold-billet section at points intermediate the ends of the latter, and means for transferring billets from the cold-billet section into the hot-billet section.

6. A furnace of the continuous type, comprising a hot-billet section, and a relatively long cold-billet section, said sections being formed as component parts of an integral structure having a division-wall between said sections, said wall having an opening connecting said sections near the charging end of the hot-billet section, and means for transferring billets from the cold-billet section to the hot-billet section.



7. A furnace of the continuous type, comprising a cold-billet section, a relatively short hot-billet section on each side of said cold-billet section, a lateral opening from each hot-billet section near the charging end thereof into the cold-billet section, lateral openings into the cold-billet section adjacent to the charging ends of said hot-billet sections, and pushers adapted to pass through said openings to transfer billets from the cold-billet section into the respective hot-billet sections.

706,083. APPARATUS FOR WASHING FAT. DAVID I. DAVIS, Kansas City, Kans., assignor to Swift and Company, Chicago, Ill., a Corporation of Illinois. Filed Feb. 1, 1902. Serial No. 92,668. (No model.)



Claim.—1. An apparatus of the class described, consisting of a tank, a carriage, means suspended from said carriage adapted to engage and

submerge the fat, and means for operating said carriage to carry said submerging means across the tank, substantially as described.

2. An apparatus of the class described, consisting of a tank, a carriage, rotary mechanism suspended from the carriage adapted to engage and submerge the fat, and means for operating said carriage to carry said rotary mechanism across the tank, substantially as described.

3. An apparatus of the class described, consisting of a tank, a rotary drum, and traveling means supporting said drum and adapted to conduct it across the tank, substantially as described

4. An apparatus of the class described, consisting of a tank, a rotary drum, and traveling means supporting said drum and adapted to conduct it across the tank, said drum having ribs on its periphery, substantially as described.

5. An apparatus of the class described, consisting of a tank, a rotary drum, traveling means supporting said drum and adapted to conduct it across the tank, and means for adjusting the height of the drum, substantially as described.

6. The combination of a tank, a carriage, a submerging device suspended from said carriage and adapted to engage and submerge matter floating on the water in the tank, and means for vertically adjusting said submerging device, substantially as described.

7. The combination of a tank, a carriage, a rotary submerging device suspended from said carriage and adapted to engage and submerge matter floating on the water in the tank, and means for vertically adjusting said submerging device, substantially as described.

8. The combination of a tank having an inclined conveyer at one end, a submerging device movable across the tank and adapted to engage and submerge matter floating on the water in the tank, and means for vertically adjusting said submerging device, substantially as described.

9. The combination of a tank having an inclined conveyer at one end, a rotary drum movable across the tank and adapted to engage and submerge matter floating on the water in the tank, and means for vertically adjusting said rotary drum, substantially as described.

10. The combination of a tank having an inclined conveyer at one end, a rotary drum movable across the tank and adapted to engage and submerge matter floating on the water in the tank, and means for vertically adjusting said rotary drum, said drum having radial ribs on its surface, substantially as described.

11. In an apparatus of the class described, the combination of a tank adapted to contain water, means for cooling the water in the tank, and means for submerging matter floating on the surface of the water in the tank, substantially as described.

12. In an apparatus of the class described, the combination of a tank adapted to contain water, and traveling means adapted to submerge matter floating on the water in the tank, substantially as described.

13. The combination of a tank, a carriage, a rotary drum pivotally suspended from said carriage and adapted to engage and submerge matter floating on the water in the tank, means for moving said carriage to cause said drum to travel across the tank, and means for vertically adjusting said drum, substantially as described.

14. The combination of a tank, a carriage having pulleys 35 38, a rotary drum, straps pivotally suspending said drum from said carriage, and means for angularly adjusting said straps, to raise or lower the drum, substantially as described.

15. The combination of a tank, a carriage, pulleys 35 38 carried by said carriage, and a flexible connection extending over said pulleys and connected with said drum for raising or lowering said drum, substantially as described.

16. The combination of a tank, a submerging device movable across the tank and adapted to engage and submerge matter floating on the water in the tank, means for vertically adjusting said submerging device, and means for discharging the matter floating on the water in the tank, substantially as described.

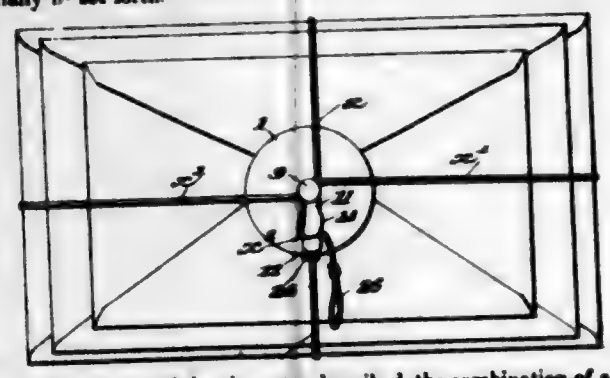
17. In an apparatus of the class described, the combination of a tank adapted to contain water, and traveling means adapted to overlie and submerge matter floating in the water in the tank, substantially as described.

18. In an apparatus of the class described, the combination of a tank adapted to contain water, traveling means movable through the water in the tank, such traveling means acting as it moves through the water in the tank to submerge matter floating therein, substantially as described.

19. In an apparatus of the class described, the combination of a tank adapted to contain water, and means arranged to travel over matter floating in the water in the tank, for submerging such floating matter, substantially as described.

706,084. PARCEL-TYING DEVICE. JAMES S. DEAN and WILLIAM H. THOMAS, Cincinnati, Ohio, assignors of one-half to Hishani Mullen, Cincinnati, Ohio. Filed Jan. 13, 1902. Serial No. 89,543. (No model.)

Claim.—1. In a device of the character described, the combination of a frame or casing, a flexible connection, a part carried by the frame or casing with which one end of said connection is engaged and on which said connection is adapted to be wound, and a clamping means carried by the frame or casing and adapted for engagement with the other end of said connection for holding it in place when passed about a parcel, substantially as set forth.



2. In a device of the character described, the combination of a frame having an opening at one side, a flexible connection passed through said opening and having an enlargement at one end, a part carried by the frame with which the other end of said connection has engagement and on which said connection is adapted to be wound and a clamping means carried by the frame and adapted for engagement with the enlarged end of the connection for holding it in place when passed about a parcel, substantially as set forth.

3. In a device of the character described, the combination of a frame having an opening, a grooved drum held to turn on the frame, a flexible connection one end of which is engaged with the drum, said connection being adapted to be wound on the drum and having its free end passed through the opening of the frame and provided with an enlargement and a clamping means carried on the frame and arranged for engagement with the enlarged end of said connection for holding it in place when passed about a parcel, substantially as set forth.

4. In a device of the character described, the combination of a frame having an opening, a grooved wheel held to turn on the frame, a spring one end of which has connection with said wheel and the other end of which is held in fixed relation to the frame, a flexible connection one end of which is engaged with the wheel, said connection being adapted to be wound on the wheel and having its free end passed through the opening of the frame and provided with an enlargement, and a clamping means carried by the frame for engagement with the free end of said connection, substantially as set forth.

5. In a device of the character described, the combination of a frame having an opening and provided with a stud, a wheel held to turn on said stud and formed with an annular chamber encircling the stud, a spring coiled in said chamber with one end connected to the wheel and its other end held in fixed relation to said frame, a flexible connection one end of which is engaged with the wheel, said connection being adapted to be wound on the wheel by the tension of the spring and having its free end passed through the opening in the frame and a clamping device carried by the frame for engagement with the free end of said connection, substantially as set forth.

6. In a device of the character described, the combination of a frame having an opening and provided with a stud, a wheel held to turn on said stud and formed with an annular chamber encircling the stud, a spring coiled in the chamber with one end connected to the wheel and its other end held in fixed relation to said frame, a plate fitted in said chamber over said spring to retain the same in position, a flexible connection one end of which is engaged with the wheel, said connection being adapted to be wound on the wheel by the tension of the spring and a clamping device for engagement with the free end of said connection, substantially as set forth.

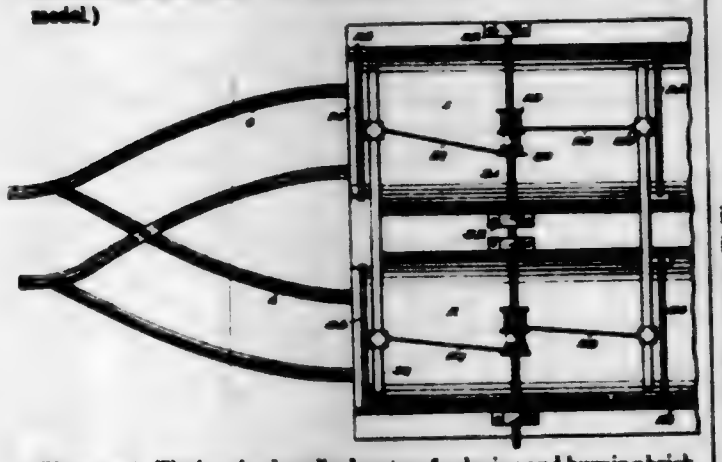
7. In a device of the character described, the combination of a frame, a flexible connection, a part carried by the frame with which one end of said connection is engaged and on which said connection is adapted to be wound, and a clamping-jaw for holding the free end of said connection and formed of a strip of metal having projections passed through the frame and clenched beneath the same and having its extremity bent upward from the frame to receive the connection between it and the frame, substantially as set forth.

8. In a device of the character described, the combination of a frame, a flexible connection, a part carried by the frame or casing with which one end of said connection is engaged and on which said connection is adapted to be wound, a clamping means carried on the frame for engagement with the free end of said connection and an undercut part projected from the frame and around which said connection is adapted to be bent, substantially as set forth.

9. In a device of the character described, the combination of a frame

or casing formed of two parts, one of which is provided with an opening, a flexible connection passed through said opening, a spring-actuated means within the casing with which said connection is engaged and on which said connection is adapted to be wound, a clamping means for holding the free end of said connection, and a screw for holding together the two parts of the casing and formed with an undercut head or enlargement projected from the casing and about which the connection is adapted to be bent, substantially as set forth.

706,085. CONTINUOUS BRICK KILN AND DRIER. JAMES F. DU BOIS, Bellaire, Ohio. Filed Oct. 24, 1901. Serial No. 79,766. (No model.)



Claim.—1. The herein-described system for drying and burning brick, comprising a drying-tunnel and a kiln-tunnel with tracks arranged therein, a vertically-movable door arranged at the exit of the drying-tunnel and a like door arranged at the inlet to the kiln-tunnel, and means whereby said doors are simultaneously elevated, as and for the purpose described.

2. The herein-described continuous system for drying and burning brick, comprising a drying-tunnel and a kiln-tunnel, a track arranged in each tunnel, a pair of vertically-movable doors arranged in the drying-tunnel adjacent the exit end thereof, a pair of vertically-movable doors arranged in the kiln-tunnel adjacent the inlet end thereof, and means whereby the outer door of each tunnel is simultaneously raised with the lowering of one door of each tunnel, as and for the purpose described.

3. The herein-described continuous system for drying and burning brick comprising a drying-tunnel and a kiln-tunnel placed side by side and in communication the one with the other, tracks arranged in said tunnels and connected adjacent to one end of the tunnels whereby the car may be switched from one tunnel to the other, and doors arranged in pairs in each tunnel and operative to retain the heat in the tunnel while the car or hack is being moved from one tunnel to the other.

4. The herein-described system for continuously drying and burning brick, comprising a drying-tunnel and a kiln-tunnel, flues leading from both sides of the kiln-tunnel to both sides of the drying-tunnel, and doors arranged adjacent to the exit end of the drying-tunnel and to the inlet end of the kiln-tunnel, as and for the purpose described.

5. A continuous brick drying and burning apparatus comprising a drying-tunnel and a kiln-tunnel placed side by side, flues establishing communication between the kiln-tunnel and drying-tunnel, said flues leading from both sides of the kiln-tunnel into the drying-tunnel, and means for establishing an uninterrupted draft through said flues, substantially as described.

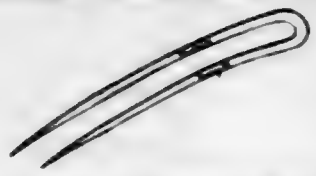
6. An apparatus for the continuous drying and burning of brick, comprising a drying-tunnel and a kiln-tunnel with a track extending the length of each, flues establishing communication between said tunnels, dampers for controlling the said flues, a pair of doors arranged adjacent to the exit end of the drying-tunnel and a like pair of doors arranged adjacent to the inlet end of the kiln-tunnel, and means for elevating the outer pair of said doors simultaneously with the lowering of the inner pair, for the purpose described.

7. The herewith-described system for the continuous drying and burning of brick, comprising a drying-tunnel and a kiln-tunnel, flues leading from both sides of the kiln-tunnel to both sides of the drying-tunnel, means for establishing an uninterrupted draft through said flues, a track throughout each tunnel to receive the cars or hacks carrying the brick, a supplemental track in each tunnel above the car-track, and means for forming a seal around the supplemental track in connection with the car, substantially as described.

8. The herein-described continuous system for drying and burning brick, comprising a drying-tunnel and a kiln-tunnel, flues leading from both sides of the kiln-tunnel to both sides of the drying-tunnel, and means for establishing an uninterrupted draft through said flues, the brick being passed into the tunnel on cars, there being a space between the piles of brick on the adjacent cars, which space serves as a combustion-chamber, and means for forming a seal around the car-bed, substantially as described.

9. The herein-described continuous system for drying and burning brick, comprising a drying-tunnel and a kiln-tunnel, flues leading from both sides of the kiln-tunnel to both sides of the drying-tunnel, and means for establishing an uninterrupted draft through said flues, tracks in said tunnels, the brick being passed through the tunnels on cars traveling on said tracks, the said brick being piled on the cars so as to produce a combustion-chamber between the piles of bricks on adjacent cars, and means for feeding fuel into said space, substantially as described.

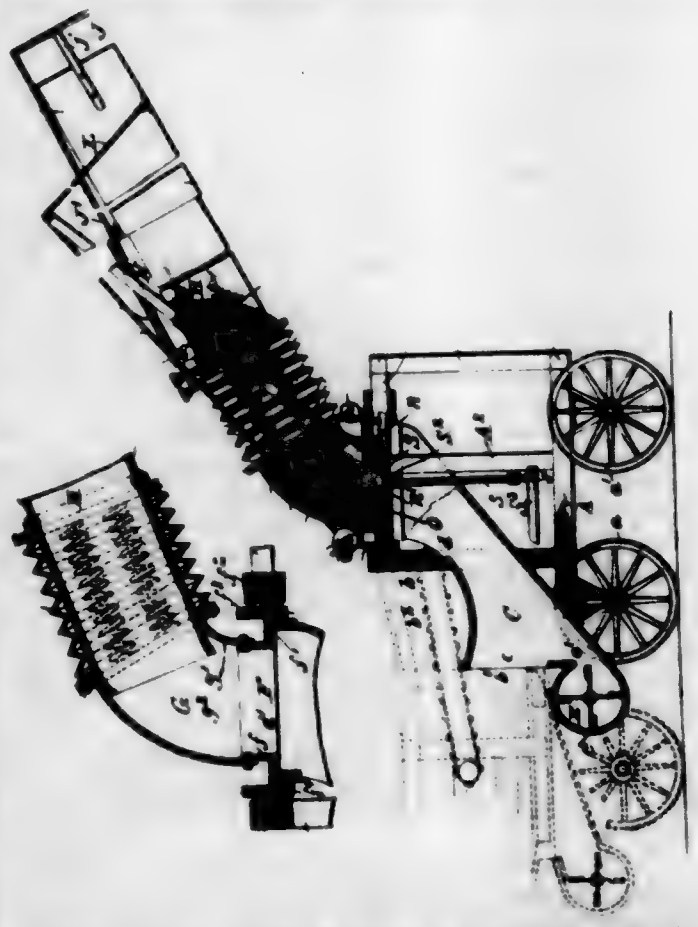
706,086. HAIR-FASTENER. WILLIAM P. DUB LAEY, Cleveland, Ohio. Filed June 18, 1900. Serial No. 20,680. (No model.)



Claim.—1. The combination of a hair-pin having a depression about its tine, with a piece of seamless elastic rubber tubing having a smaller internal diameter than the external diameter of the tine and adapted to be slipped upon the tine and seated in said depression, substantially as described.

2. A hair-pin having an annular recess about its tine which recess is deeper at its edges than intermediately, combined with a removable sheathing consisting of a soft-rubber tube which surrounds the tine and occupies said recess, substantially as described.

706,087. PNEUMATIC STACKER. JOHN H. EDWARD, Pretty Prairie, Kans., assignor to the Indiana Manufacturing Company, Indianapolis, Ind., a Corporation of West Virginia. Original application filed Jan. 5, 1899, Serial No. 451,328. Divided and this application filed Dec. 9, 1901. Serial No. 85,253. (No model.)



Claim.—1. In a pneumatic stacker, the combination with a horizontally-rotary hood, and a vertically-adjustable delivery tube or chute, of the longitudinally-extensible flexible joint secured to the hood to move horizontally therewith and also secured to the chute or spout to move vertically therewith, substantially as set forth.

2. The combination, in a pneumatic stacker, of a horizontally-rotary hood, an air chute or spout having its inner end telescopically connected with said hood, and its outer end vertically adjustable, and the longitudinally-extensible, air-tight, flexible cover surrounding the adjacent ends of and rigidly secured to both said hood and chute, substantially as set forth.

3. In a pneumatic stacker, the combination of a hood, a delivery-duct having a vertically-adjustable outer end and having its inner end movably connected to the hood, a support for the outer end of the de-

livery-duct connected with the main frame, a rotary base for the aforesaid parts, and a flexible, extensible cover connected to the hood and to the delivery-duct, substantially as set forth.

4. In a pneumatic stacker, the combination of a hood, a delivery-duct, an adjustable support for the outer end of said delivery-duct, means for adjusting said support to vary the elevation of the discharge end of said chute, a flexible joint connecting the said delivery-duct and the hood and extensible longitudinally of the said delivery-duct, and a horizontally-rotary base for all of the said parts, substantially as set forth.

5. The combination, in a pneumatic stacker, of the lower or inner chute or hood, the chute or trunk movably connected with said hood, and the springs arranged to bear upward and outward against the outer chute, substantially as set forth.

6. In a pneumatic stacker, the combination with the lower section or hood, and the chute or spout communicating therewith, of a flexible cover surrounding the adjacent sections of the hood and chute, and springs connecting the hood and chute, substantially as set forth.

706,088. SHOE-TURNING MACHINE. ANDREW EYTLER, Jr., Boston, Mass., assignor to United Shoe Machinery Company, Paterson, N. J., a Corporation of New Jersey. Filed Oct. 10, 1901. Serial No. 78,188. (No model.)

Claim.—1. A shoe-turning machine, having, in combination, a central support, a form-carrying turret projected from one side of said support, and a yoke for supporting a turning implement supported from the opposite side of said support, substantially as described.

2. A shoe-turning machine, having, in combination, a central support, a yoke for supporting a turning implement projected from one side of said support, a vertically-adjustable bracket projected from the opposite side thereof, and a form-carrying turret mounted upon said bracket, substantially as described.

3. A shoe-turning machine, having, in combination, a turning implement, and a form having an aperture extending from a point toward the toe to a point toward the heel, substantially as described.

4. A shoe-turning machine, having, in combination, a turning implement, a form having provision to permit the sole of a shoe to be bent inward, and an auxiliary turning implement for engaging the sole and bending it inward, substantially as described.

5. A shoe-turning machine, having, in combination, a turning implement, a form, and means for preventing the sole of a shoe on the form from bending outward during the turning operation, substantially as described.

6. A shoe-turning machine, having, in combination, a form, a turning implement supported to engage the toe of a shoe on the form, and an auxiliary turning implement supported to engage the sole, said form and auxiliary turning implement being relatively movable to transfer the point of engagement of the auxiliary turning implement with the sole along the sole during the turning operation, substantially as described.

7. A shoe-turning machine, having, in combination, a form, a turning implement supported to engage the toe of a shoe on the form, an auxiliary turning implement movable longitudinally of and transversely to the form to engage the sole back of the toe, and means for actuating the auxiliary turning implement, substantially as described.

8. A shoe-turning machine, having, in combination, a turning implement, a form having a recess into which the sole of the shoe can be bent, and means for bending the sole into said recess, substantially as described.

9. A shoe-turning machine, having, in combination, a turning implement and a form having a cut-away portion extending from a point toward the toe to a point toward the shank for preventing the binding of the upper on the form, substantially as described.

10. A shoe-turning machine, having, in combination, a form, a turning implement supported to engage the toe of a shoe on the form and having at its working end a laterally-projecting lip, and an auxiliary turning implement, the working end of which is movable from a position behind said lip into position to engage the sole of a shoe on the form back of the toe, substantially as described.

11. A shoe-turning machine, having, in combination, a form, a turning implement supported to engage the toe of a shoe on the form, an auxiliary turning implement supported adjacent to the turning implement and movable with relation thereto, and mechanism for actuating the auxiliary turning implement, substantially as described.

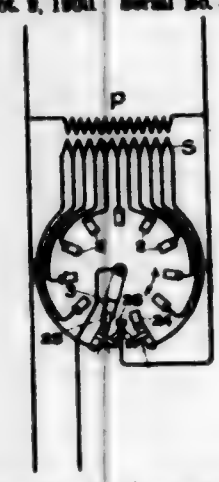
12. A shoe-turning machine, having, in combination, a form, a turning implement, an auxiliary turning implement, and means for simultaneously moving both implements out of operative relation to the form to permit a shoe to be placed thereon, substantially as described.

13. A shoe-turning machine, having, in combination, a form, and a turning implement and auxiliary turning implement movable with and independently of each other, substantially as described.

14. A shoe-turning machine, having, in combination, means for interiorly supporting the shoe to be turned, a turning implement, and means exteriorly engaging the sole and movable along the same during the turning operation to insure its proper bending, substantially as described.

15. A shoe-turning machine, having, in combination, a turning implement, a form, and an auxiliary turning implement for engaging the sole of a shoe on the form and preventing it from bending outward during the turning operation, substantially as described.

708,089. ELECTRIC REGULATOR. AUGUSTUS R. EVERETT, Lynn, Mass., assignor to General Electric Company, a Corporation of New York. Filed Oct. 9, 1900. Serial No. 32,681. (No model.)



Claim.—1. The combination of a regulating-winding connected to a row of contacts, and a circuit having one terminal connected to a movable contact coöperating with said row of contacts and the other terminal to a switch-arm adapted to make electrical connection with either of two of the contacts of said row of contacts.

2. In a potential-regulator, the combination of a row of fixed contacts, a movable contact for coöperating with said fixed contacts, and a change-over switch brought into operation as the movable contact passes from one fixed contact to another and coöperating with said movable contact to reverse the connections of said row of fixed contacts or a portion thereof with respect to the circuit to be regulated.

3. The combination of a row of fixed contacts, a movable contact arranged to step from fixed contact to fixed contact, a coöperating change-over switch, a circuit to be regulated, and connections between one terminal of said circuit and said movable contact and also between the other terminal of said circuit and said change-over switch.

4. In a regulator, the combination of a regulating-winding, a row of contacts connected to said winding, a movable contact for traversing said fixed contacts, and a cam-actuated change-over switch for connecting one terminal of the circuit to be regulated to either one of two of said fixed contacts.

5. The combination of a row of fixed contacts, a movable contact coöperating therewith, and a circuit connected with one terminal to the movable contact and the other to a supplemental fixed contact.

6. The combination of a row of fixed contacts, a movable contact coöperating therewith, and a circuit connected with one terminal to the movable contact and the other to a supplemental contact located between two of the fixed contacts.

7. The combination of a plurality of fixed contacts, a movable contact coöperating therewith, and a supplemental contact between which and the movable contact current temporarily passes across an intervening space.

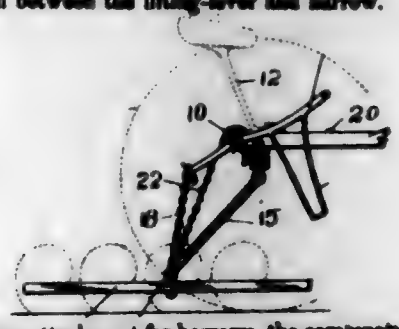
8. The combination of a plurality of fixed contacts, a movable contact arranged to step from fixed contact to fixed contact and a supplemental contact between which and the movable contact current may pass as the movable contact passes from one fixed contact to another.

706,040. SULKY ATTACHMENT FOR HARROWS. HENRY T. PAINE, Spencer, Mass. Filed Apr. 14, 1902. Serial No. 102,703. (No model.)

Claim.—1. In a riding attachment for harrows, the combination of a wheeled vehicle, a drag-frame connecting the vehicle with a harrow, a lifting-lever, a connection from the lifting-lever acting on the harrow-frame in front of its center of gravity, and a part engaged by the front end of the harrow when lifted, holding the harrow from tipping.

2. In a riding attachment for harrows, the combination of a wheeled

vehicle, a drag-frame connecting the vehicle with a harrow, a lifting-lever having a steadying-arm engaging the harrow when in raised position, and a connection between the lifting-lever and harrow.

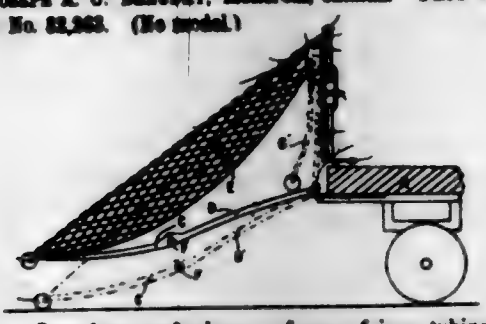


3. In a riding attachment for harrows, the combination of a wheeled vehicle, a drag-frame connecting the vehicle with a harrow, a lifting-lever, a connection between the lifting-lever and harrow, and a spring assisting the operation of the lifting-lever in raising the harrow.

4. In a riding attachment for harrows, the combination of a wheeled vehicle, a drag-frame connecting the vehicle with a harrow, a lifting-lever having a steadying-arm engaging the harrow when in its raised position, and a chain serving as an adjustable connection between the lifting-lever and harrow.

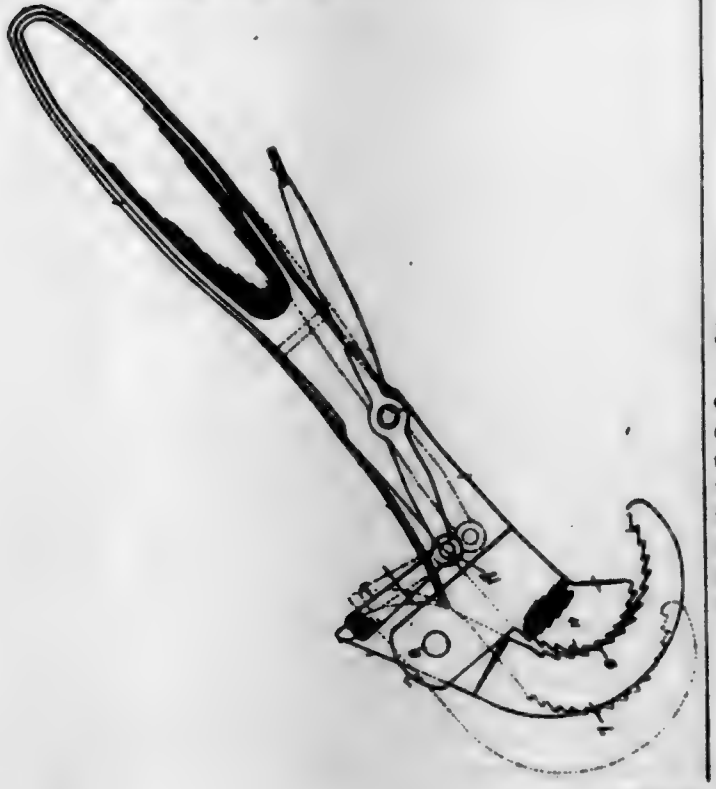
5. In a riding attachment for harrows, the combination of a wheeled vehicle, means connecting the wheeled vehicle with a harrow-frame, a lifting-lever connected to the harrow-frame, a coiled spring, a sprocket-wheel operated by the coiled spring, and a chain adjustably connecting the sprocket-wheel to the harrow-frame.

706,041. CAR-FENDER. ALBERT H. FERGUSON, Ste. Cunégonde, and JOSEPH A. U. BEAUDRY, Montreal, Canada. Filed Nov. 14, 1901. Serial No. 82,263. (No model.)



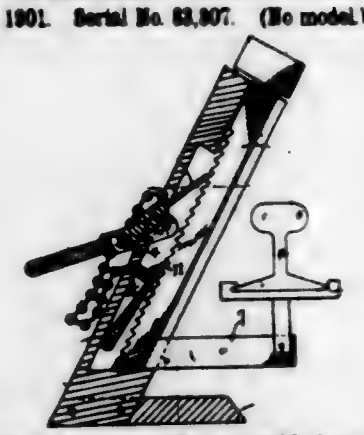
Claim.—In safety car-fenders: a frame of iron tubing in two sections articulated in compass-joints, hooks to attach the same to cars, two rubber-tired wheels to roll on the rails, a netting of metal bands, chains to suspend said fender to a horizontal rod chained to the splash-board and supported on hooks, a landing bagging-net of fabric fastened on its four sides, two supporting-chains, a vertical rod branching to the ends of the horizontal rod, for the purpose and in the manner hereinabove described.

706,042. WRENCH. CHARLES C. FIELDS, Morristown, Tenn. Filed July 27, 1901. Serial No. 69,897. (No model.)



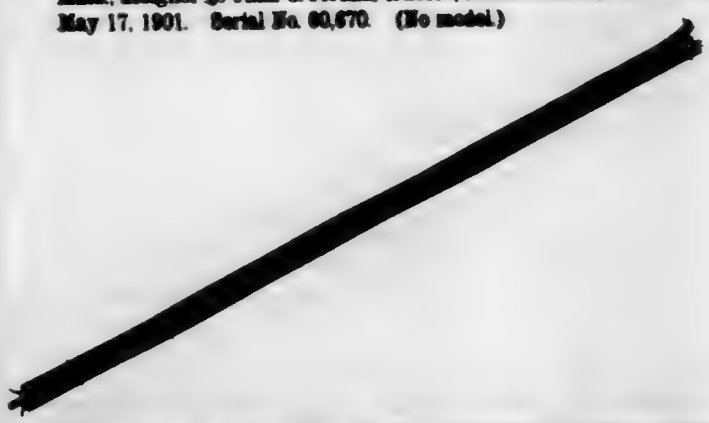
Claim.—A wrench comprising a body portion, having at one end an integral handle or hand-grasp and at the other end an integral fixed jaw provided with a convex gripping-surface having outwardly-inclined teeth, said body portion also having, adjacent to the fixed jaw, rearwardly-projecting parallel legs formed integral therewith, a movable jaw having a concave gripping-surface with inwardly-inclined teeth, and a shank pivotally mounted between the legs of the body and extending beyond the same, said extension being curved or cut away, as described, a leaf-spring secured at one end to the back of the body of the wrench and having its free end bearing against the extension of the shank of the pivoted jaw, a lever pivoted between its ends on the side of the body of the wrench, moving in a plane parallel with and immediately adjacent to the side of said body, and having one end located immediately adjacent to the handle or hand-grasp, in position to be operated by the thumb or fingers of the hand without shifting the grasp, being provided with a finger-plate at right angles to the plane of the body of the wrench, and a link pivotally connected at one end to the other end of the lever, the other end of said link being pivoted to the extension of the shank of the pivoted jaw, substantially as described.

706,048. LIFTING-JACK. OLIVER E. FIELDS, Duncannon, Pa. Filed Nov. 26, 1901. Serial No. 83,807. (No model.)



Claim.—A lifting-jack comprising a suitable base, a hollow post extending therefrom, the post having a longitudinal rear open slot, and a front closed slot, a sliding rack-bar in the post, a bracket projecting from the rack-bar through the open slot of the post, a shoe at the outer end of the bracket, an operating-lever pivoted in the post and projecting from the same in a direction opposite from the bracket, a gravity-pawl pivotally mounted on the lever and engaging the teeth of the rack-bar, a spring-actuated pawl pivoted below the lever and adapted to be automatically forced to an open position for the support of the rack-bar when the latter has become sufficiently elevated, and a chain for retracting the pawls, the parts operating substantially as, and for the purpose set forth.

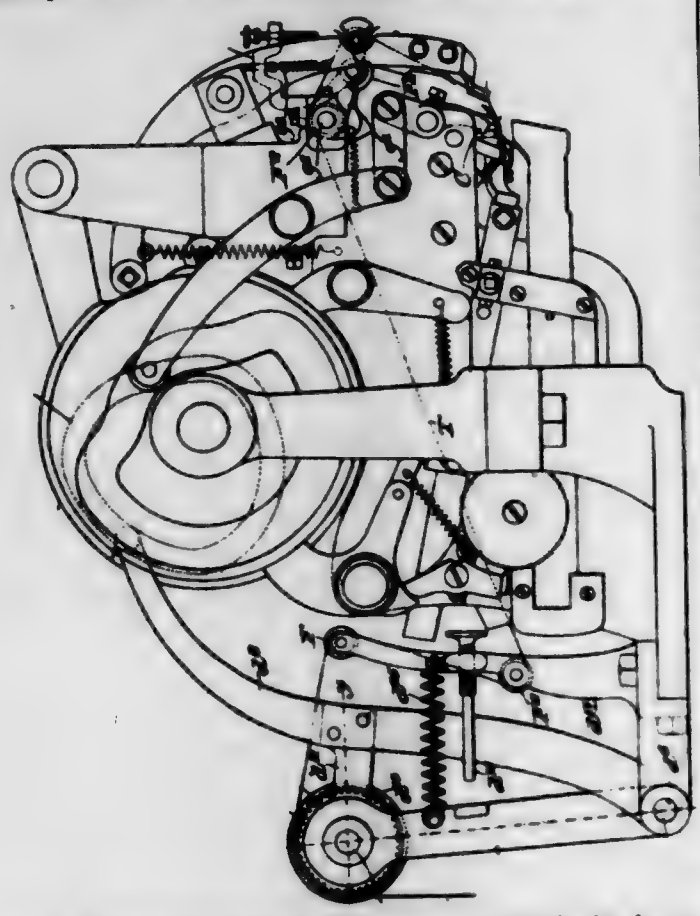
706,044. MACHINE-BELTING. MARTIN GILLET, Arlington Mass., assignor to Julia G. Jordan, trustee, Merchantville, N. J. Filed May 17, 1901. Serial No. 60,670. (No model.)



Claim.—As an article of manufacture, waterproof machine-belting composed of layers of untreated textile fabric and of paper on both sides of the textile fabric, the paper rendered insoluble in water and hygroscopic, the said layers being united solely by pressure while the paper is in a comparatively soft and plastic condition intimately to combine the fibers of the paper with the meshes of the fabric, whereby the use of cement or glue is avoided, the hygroscopic character of the paper preventing it from becoming hard and brittle, the prepared paper constituting the outside layers of the laminated belting.

706,045. TAKE-UP AND TENSION FOR SEWING-MACHINES. ALEXANDER GODFREY, Haverhill, Mass., assignor to United Shoe Machinery Company, Paterson, N. J., a Corporation of New Jersey. Filed Oct. 29, 1898. Renewed Oct. 9, 1901. Serial No. 78,190. (No model.)

Claim.—1. A hook-needle chain-stitch shoe-sewing machine, having, in combination, stitch-forming mechanism, and a movable, cam-actuated tension device acting, while the needle is in the material, to tighten the loop which is around its shank, substantially as described.



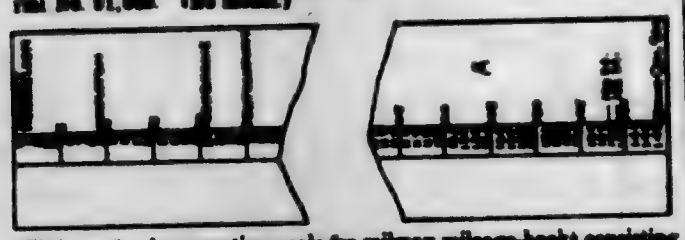
2. A hook-needle, chain-stitch shoe-sewing machine, having, in combination, stitch forming and setting mechanism, comprising a movable, cam-actuated stitch-setting tension device, and a spring exerting a gradually-increasing strain on the thread while the stitch is being set, substantially as described.

3. A hook-needle chain-stitch shoe-sewing machine, having, in combination, stitch-forming mechanism, and a movable, cam-actuated tension device acting, while the needle is in the material, to tighten the loop which is around its shank, and to set the stitch of which the loop interlocked therewith forms a part, substantially as described.

4. A hook-needle chain-stitch shoe-sewing machine, having, in combination, stitch-forming mechanism, a thread-trunk, means for intermittently locking and unlocking said trunk, and a cam and suitable connections for actuating said trunk while locked to exert a pull on the thread, substantially as described.

5. A hook-needle chain-stitch shoe-sewing machine, having, in combination, stitch-forming mechanism, a thread-trunk, means for intermittently locking and unlocking said trunk, and a cam and suitable connections for moving said trunk bodily while locked to exert a pull on the thread, substantially as described.

706,046. COMPUTING-SCALE FOR RAILWAY MILEAGE-BOOKS. JOHN S. GOLDTHWAITE, Albany, N. Y. Filed Jan. 28, 1902. Serial No. 91,662. (No model.)

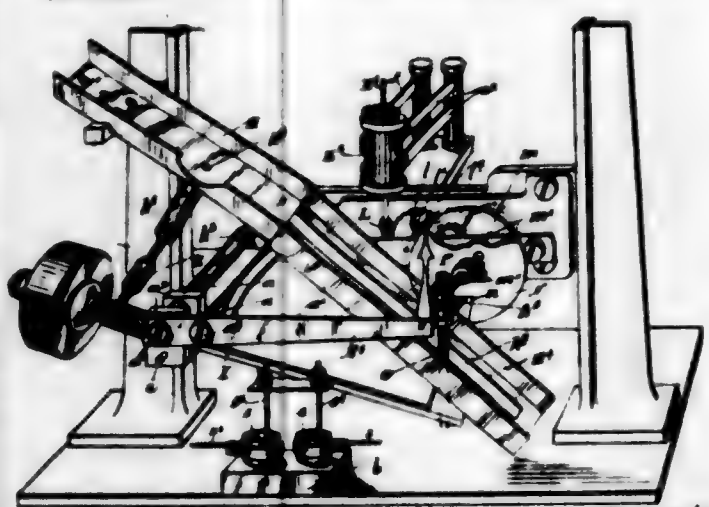


Claim.—1. A computing-scale for railway mileage-books consisting of a rule or tape having marked thereon as many divisions or spaces as there are miles of length in the portion of the railroad upon which said computing-scale is designed to be used, said spaces being numbered consecutively to correspond with the number of miles from the starting-point to the terminus thereof; and having the names of the stations along said portion placed opposite the numbers designating the number of miles of the respective stations from the starting-point; said spaces being of uniform length and equal in length to the length of a mileage-coupon of the railway mileage-books issued for passenger travel upon said railroad, whereby said rule or tape is constructed and adapted for use in conjunction with said railway mileage-book having a long strip or ribbon of paper with mileage-coupons printed thereon, substantially as described, and for the purposes set forth.

2. A computing-scale for railway mileage-books consisting of a rule or tape having marked thereon upon both sides thereof as many divisions or spaces as there are miles of length in the portion of railroad upon which the computing-scale is designed to be used; said spaces being numbered consecutively on one side of said scale to correspond with the number of miles from one end of said portion of railroad, and on the reverse side of said scale numbered in like manner commencing at the opposite end of said portion of railroad; said scale having thereon the names of the stations along said railroad placed opposite the numbers designating the number of miles of the respective stations from the respective starting-point; and each of said spaces being in length equal to the length of a mileage-coupon of the railway mileage-book issued for passenger travel on said railroad; whereby said rule or tape is constructed and adapted for use in conjunction with said railway mileage-book having a long strip or ribbon of paper with mileage-coupons printed thereon; substantially as described and for the purposes set forth.

3. A computing-scale for railway mileage-books made by marking off a rule or tape into as many divisions or spaces as there are miles of length in the railroad, or some portion or division thereof, upon which said computing-scale is designed to be used; said spaces being numbered consecutively to correspond with the number of miles from the starting-point to the terminus thereof; and having the names of the stations along said railroad, or the said division thereof, placed opposite the numbers designating the number of miles of the respective stations from the starting-point; said spaces being of uniform length and equal in length to the length of a mileage-coupon of the railway mileage-books issued for passenger travel upon said railroad; in combination with the said railway mileage-book, composed of a long strip or ribbon of paper with mileage coupon-tickets printed thereon and suitably attached at one end between two covers, of which covers the one next the face side of said mileage-strip is provided with a slot adapted to admit the said computing-scale to pass through it and lie upon the face side of said mileage-strip, substantially as described and for the purposes set forth.

706,047. PREPAYMENT ELECTRIC METER. GEORGE L. GOWLAND, Peterborough, Canada. Filed Aug. 21, 1901. Serial No. 72,737. (No model.)



Claim.—1. The combination with the motor supported on a suitable frame and having one circuit-wire extending therethrough and the other circuit-wire and contacts separating the ends of the same, of a gravitating coin-slide, a lever suitably pivoted and supporting the slide at one end, the counterpoising weight at the opposite end of the lever, the contacts connected to the lever and rotatable current-indicating means interposed between the slide and the motor and operated from the latter whereby when the slide is depressed by the coin the contacts are thrown in and the measuring means set in motion as and for the purpose specified.

2. In a prepayment-meter, a motor with electric connections thereto, a switch included in said connections, a coin-slide adapted to swing downward under the weight of the coin, an indicator having driving connections with the motor, means whereby the coin-slide when in its elevated position holds the indicator against movement, but releases it on the depression of the coin-slide, and means whereby the depression of the coin-slide operates the switch to close the circuit through the motor, substantially as described.

3. The combination with the motor supported on a suitable frame and having one circuit-wire extending therethrough and the other circuit-wire and contacts separating the ends of the same, of a gravitating coin-slide provided with a longitudinal slot and a laterally-extending pin, a cross-spindle, an arm extending outwardly from the cross-spindle into the slot and designed to form a stop for the coin, a disk secured on the cross-

spindle and provided with a notch to coact with the pin extending laterally from the slide and a suitable driving means from the motor to the cross-spindle and the contact-pins connected with the slide and designed to be depressed by the depression of the slide as and for the purpose specified.

4. The combination with the motor supported on a suitable frame and having one circuit-wire extending therethrough and the armature vertically disposed and supported in suitable bearings and the other circuit-wire and contacts separating the ends from the same, of a gravitating coin-slide, the contact-pins connected with the same and rotatable current-indicating means interposed between the slide and the motor and driving means connecting such aforesaid means to the armature-shaft whereby on the depression of the slide the circuit is completed and the measuring means set in motion as and for the purpose specified

5. The combination with the motor supported on a suitable frame and having one circuit-wire extending therethrough and the armature vertically disposed and supported in suitable bearings and the other circuit-wire and contacts separating the ends of the same, of a gravitating coin-slide having a slot, the contact-pins connected to the same, the pin extending laterally from the slide, the cross-spindle, the disk secured on the same provided with a suitable notch to coact with the pin, the arm secured on the spindle and extending into the slot in the slide, the driving-gear connecting the armature-shaft and spindle, the said slide being designed to be depressed by the coin so as to throw in the contact-points and throw the pin on the periphery of the disk and the arm being designed to revolve so as to free the coin as soon as the pin has been started to ride upon the surface of the disk as and for the purpose specified.

6. The combination with the motor supported on a suitable frame and having one circuit-wire extending therethrough and the other circuit-wire and contacts separating the ends of the same, of a stationary slide, a supplemental gravitating coin-slide forming a continuation thereof, a circuit-closer operatively connected with said gravitating slide, a stop extending into the stationary slide and means whereby when the coin is deposited into the gravitating slide, so as to depress the same and the circuit is thrown in, the said slide operates upon the stop in the stationary slide, so as to form an obstruction to the passage of another coin as and for the purpose specified.

7. The combination with the motor supported on a suitable frame and having one circuit-wire extending therethrough and the other circuit-wire and contacts separating the ends of the same, of a stationary slide having a depending sleeve, a supplemental gravitating coin-slide forming a continuation thereof, a lever to which the gravitating slide is connected, a countervailing weight on such lever, a pin extending over one end of the lever through the sleeve into the stationary slide, the said gravitating slide when depressed by the coin, so as to throw in the circuit tilting the lever, so as to throw up the pin to form a stop on the slide as and for the purpose specified.

8. The combination with the stationary slide, and the balanced slide at one end thereof adapted to be depressed by the weight of a coin, of a pivoted lever supporting said balanced slide and a pin connected with and extending into the stationary slide, said pin being raised by the depression of the lever under the action of the balanced slide, substantially as described.

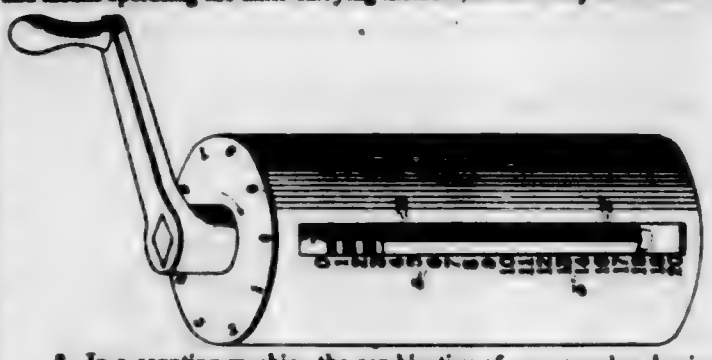
9. In combination with the stationary slide, a lever connected to the same, a gravitating slide supported on the lever, a pin extending through one end of the lever into the stationary slide and raised by the depression of the lever, substantially as described.

10. In a device of the class described, the combination with the gravitating slide suitably supported and having a slot therein, of the cross-spindle suitably driven from the motor, the arm secured to the same and extending through said slot in the gravitating slide and designed to form a temporary stop for the coin when deposited and the disk also secured to the same and provided with the countervailing weight to balance the arm as and for the purpose specified.

706,048. COUNTING-MACHINE. THOMAS W. GRAHAM, Dubuque, Iowa. Filed Mar. 5, 1902. Serial No. 96,893. (No model.)

Claim.—1. In a counting-machine the combination of one member bearing tens and hundreds figures, a second member carrying units figures and so disposed relative to said first-mentioned member that it may be progressively operated to successively bring the respective units figures into registration with the tens and hundreds figures of the first-mentioned member whereby said figures are collocated to form consecutive numbers, and means for progressively operating the units-carrying member; substantially as described.

2. In a counting-machine the combination with one member bearing tens and hundreds figures, a second member carrying units figures and so disposed relative to said first-mentioned member that it may be rotatively operated to successively bring the respective units figures into registration with the tens and hundreds figures of the first-mentioned member whereby said figures are collocated to form consecutive numbers, and means operating the units-carrying member, substantially as described.



3. In a counting-machine the combination of one member having tens figures arranged in approximate alinement, a second member carrying units figures arranged around the periphery thereof and adapted to be successively brought into registration with the tens figures whereby said figures are collocated to form consecutive numbers, and means for rotating said units-carrying member and shifting the same during such rotation along the tens figures.

4. In a counting-machine the combination of a slotted cylindrical member having tens figures arranged in approximate alinement alongside said slot, said member having a spiral thread on its interior, and a second member carrying units figures arranged around the periphery thereof and grooved spirally to engage the interior thread of the cylinder, and means for rotating the units-carrying member and shifting the same longitudinally of the cylinder to cause the units figures to register with the tens figures; whereby said figures are collocated to form a single resultant number; substantially as described.

5. In a counting-machine the combination of one member provided with tens figures arranged in approximate alinement and provided with grooves on its surface, and a second member carrying units figures arranged around the periphery thereof and provided with spiral threads adapted to engage the grooves on the surface of the tens-carrying member, and means for operating the units-carrying member to rotate and cause the same to travel along the tens figures, whereby said figures are collocated to form a single resultant number; substantially as described.

6. In a counting-machine the combination of a slotted cylinder having tens figures arranged in approximate alinement alongside said slot, a second member adapted to be rotated within and shifted longitudinally of said cylinder and carrying units figures arranged around its periphery, means for operating the units-carrying member to cause the units figures to register with the tens figures whereby said figures are collocated to form a single resultant number, and an indicator disposed in circular arrangement upon the end of the cylinder adapted to designate the extent of movement of the operating means; substantially as described.

7. In a counting-machine the combination of one member having tens figures arranged in approximate alinement, a second member carrying units figures arranged around its periphery, and an operating-shaft in loose engagement with the units-carrying member and adapted to rotate the same, and means for shifting the units-carrying member along the shaft during its rotation to cause the units figures to successively register with the successive tens figures whereby said figures are collocated to form a single resultant number; substantially as and for the purpose described.

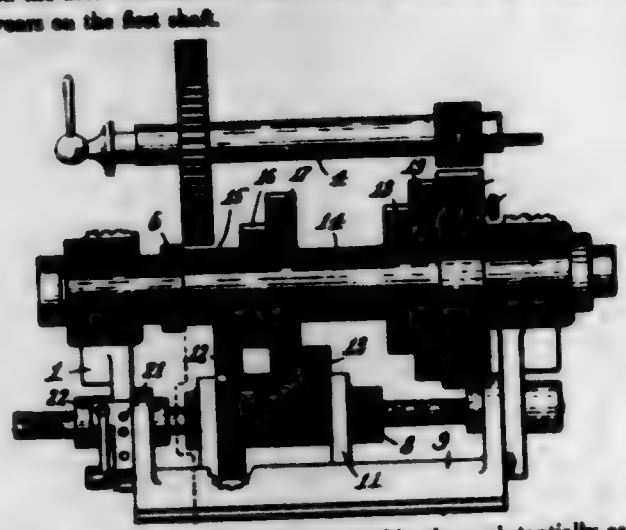
8. In a counting-machine the combination of a fixed member bearing tens and hundreds figures, and a movable member carrying units figures and adapted to be operated to cause the units figures to successively register with the tens and hundreds figures whereby said figures are collocated to form a single resultant number; substantially as described.

9. In a counting-machine the combination of a slotted cylinder having tens figures arranged alongside said slot, a member adapted to be rotated within and shifted longitudinally of said cylinder and carrying units figures arranged around its periphery, and means for operating the units-carrying member to cause the units figures to successively register with the tens figures whereby said figures are collocated to form consecutive numbers, substantially as described.

10. In a counting-machine the combination of one member bearing units figures, and a second member bearing tens figures, one of said members being fixed relative to the other whereby said other member may be operated to cause its figures to successively register with the figures of the fixed member whereby said figures are collocated to form consecutive numbers, substantially as described.

706,048. VARIABLE-SPEED DEVICE. ISAAC H. W. HANSEN and FREDERICK W. GORDON, Hartford, Conn., assignors to Pratt & Whitney Company, Hartford, Conn. Filed Mar. 24, 1902. Serial No. 99,581. (No model.)

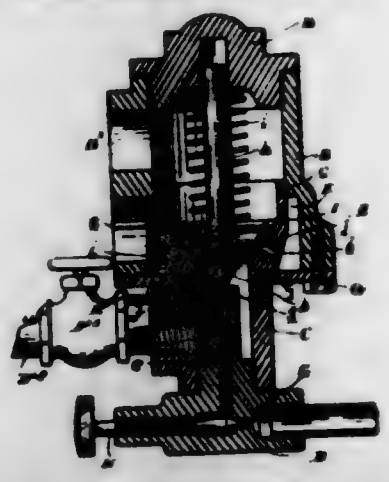
Claim.—1. In a variable-speed device, the combination, substantially as set forth, of a first shaft, a series of diversely-sized gears thereon, a second shaft parallel with the first one, a gear thereon, a longitudinally and angularly adjustable geared tumbler, and a compound intermediate gear carried by said tumbler and driven by the gear on the second shaft and adapted to have one of its members engage with some of the gears on the first shaft and its other member alternatively engage with other gears on the first shaft, said diversely-sized gears being rigidly united with each other and being loose on the first shaft, a gear fast on the first shaft, a pair of gears united with each other on a common axis parallel with the first shaft and adapted to have one of its members engage one of said diversely-sized gears and its other member engage the gear fast on the first shaft, and means for locking said diversely-sized gears to the first shaft.



2. In a variable-speed device, the combination, substantially as set forth, of a first shaft, a series of diversely-sized gears thereon, a second shaft parallel with the first one, a gear thereon, a longitudinally and angularly adjustable geared tumbler, a compound intermediate gear carried by said tumbler and driven by the gear on the second shaft and adapted to have one of its members engage with some of the gears on the first shaft and its other member alternatively engage with other gears on the first shaft, said diversely-sized gears being rigidly united with each other and being loose on the first shaft, a gear fast on the first shaft, a pair of gears united with each other on a common axis parallel with the first shaft and adapted to have one of its members engage one of said diversely-sized gears and its other member engage the gear fast on the first shaft, and means for locking said diversely-sized gears to the first shaft.

3. In a variable-speed driving device for engine-lathes, the combination, substantially as set forth, with the head-stock, arbor, face-gear, back gear, and face-gear clutch, of a series of diversely-sized unified gears loose on the lathe-arbor and adapted to be locked thereto by the clutch, a driving-shaft mounted on the head-stock parallel with the arbor, a gear on said driving-shaft, a longitudinally and angularly adjustable gear-carriage, a compound intermediate gear carried by said gear-carriage and driven by the gear on said driving-shaft and adapted to have one of its members engage with some of the diversely-sized gears on the lathe-arbor and its other member engage alternatively with other of the diversely-sized gears on the lathe-arbor, and means for locking said gear-carriage in selective position.

706,050. MIXING-VALVE FOR GAS OR GASOLENE ENGINES. ROY E. HARDY, Detroit, Mich., assignor, by mesne assignments, to Hardy Motor Works, Limited, Port Huron, Mich., a Corporation of Michigan. Filed May 6, 1901. Serial No. 58,864. (No model.)



Claim.—1. In a mixing-valve for gas or gasolene engines, the combination with a casing, of a mixing-chamber for either gas and air or gasolene and air having a seat, a valve for the seat, air-inlet ports controlled by said valve, a valve-controlled gas-inlet opening below the seat, a valve-controlled gasolene-inlet opening projecting in proximity to the main valve and having a seat formed at its upper end, and a secondary valve carried by said valve adapted to seat against said inlet-opening.

2. In a mixing-valve for gas or gasolene engines, the combination with a casing, formed with a seat, of a valve for the seat mounted in the casing, a gas-inlet passage formed in the casing below the seat, and air-inlet ports leading into the seat, a gasolene-inlet port leading into proximity to the main valve, and a secondary valve carried by the main valve adapted to control said port.

3. In a mixing-valve for gas or gasolene engines, the combination with a casing, a valve and valve-seat in the casing, of a series of air-inlet ports leading into the seat, a gas-inlet formed in the casing below the seat, a valve-controlled gasolene-inlet passage extending into proximity to the valve and formed with a seat, a spring-backed secondary valve mounted in the main valve adapted to control said passage, said valve being free to have a limited movement irrespective of the main valve.

4. In a mixing-valve for gas or gasolene engines, the combination with a casing, of a main valve, and corresponding valve-seat formed in the casing, an air-inlet passage surrounding the valve-seat, and ports leading into the valve-seat controlled by said valve, a gas-inlet below said valve, and a valve-controlled gasolene-inlet extending into proximity to said valve, a valve-seat formed in the end of said gasolene-inlet, and a secondary valve carried by the main valve adapted to seat against said inlet.

5. In a mixing-valve for gas or gasolene engines, the combination with a casing formed with a mixing-chamber in communication with the cylinder, air, gas, and gasolene passages in communication with said chamber, a valve-seat formed in said casing, and a valve adapted to said seat controlling communication between said passages and the mixing-chamber, and an independently-movable valve carried by said valve adapted to control the gasolene-passage.

6. In a mixing-valve, the combination of a mixing-valve chamber for either gas or gasolene, having a seat, a valve for the seat guided in said chamber, valve-controlled gas and gasolene inlet openings below the seat, air-ports leading into the seat, said valve being adapted to control communication between said air gas and gasolene openings and said chamber, and a secondary valve yieldingly mounted in said valve and adapted to individually control said gasolene-inlet opening.

7. In a mixing-valve for gas or gasolene engines, the combination of the three-part casing, B, C, D, formed with the vapor, air, gas and gasolene inlet passages B^2, E, F and G, respectively, the cap B' and the valve I having its stem guided in said cap, and the spring *i* sleeved thereon, said valve being adapted to control communication between the air, gas and gasolene passages E, F and G, and the vapor-inlet passage B^2 as and for the purpose described.

8. In a mixing-valve for gas or gasolene engines, the combination of the three-part casing, B, C and D, formed with air, gas and gasolene inlet openings and an outlet-opening, the part C having an upward extension *c* adapted to fit within the part B and formed with a valve-seat, and air-ports *b* in said seat and the spring-backed valve I guided in said casing and adapted to said seat to control communication between said inlet and outlet passages.

9. In a mixing-valve, the combination with a casing, formed with a valve-seat, and air, gas and gasolene inlet openings below said seat and an outlet-opening above said seat of a two-part valve adapted to said seat comprising the spring-backed main valve I adapted to control communication with the outlet-opening and the spring-backed secondary valve J mounted within the main valve and adapted to control the gasolene-inlet port, comprising a plunger formed with a stop *k* and the spring *j* of lesser strength than that of the main valve.

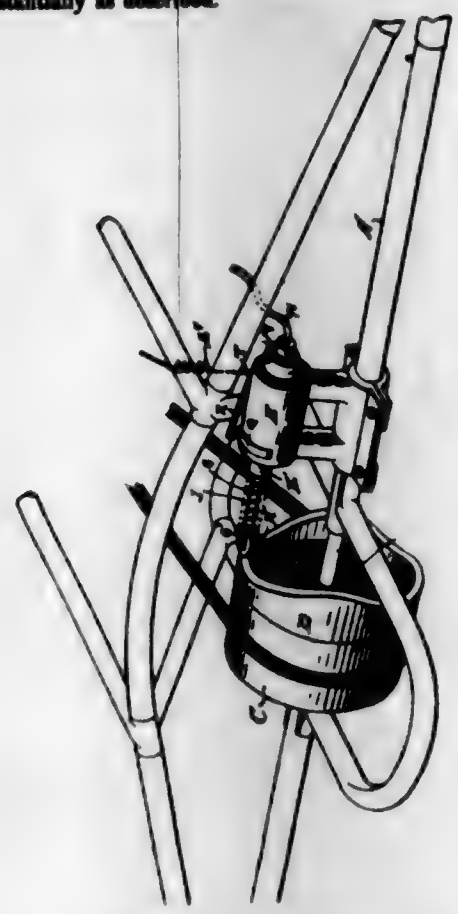
706,051. AUTOMOBILE AIR-PUMP. JOHN G. HEAL, Detroit, Mich. Filed Sept. 24, 1901. Serial No. 76,246. (No model.)

Claim.—1. The combination of a driving-axle, a crown-cam mounted thereon, an air-pump fixedly located perpendicularly to the plane of the cam-wheel, the piston-rod thereof engaging the cam and actuating the piston of the air-pump to compress air therein, elastic means for retracting the piston and the piston-rod, a clamp adapted to frictionally engage the piston-rod, and means connected with the clamp operated by hand whereby the clamp can be brought into engagement with the piston-rod at the will of the operator, substantially as described.

2. The combination of a driving-axle, a crown-cam mounted thereon, an air-pump fixedly located perpendicularly to the plane of the cam-wheel, the piston-rod thereof engaging the cam and actuating the piston of the air-pump to compress air therein, elastic means for retracting the piston and the piston-rod, a clamp adapted to frictionally engage the piston-rod, a valve in a passage opening into the clearance-space of the pump, means for simultaneously actuating the valve and the clamp whereby the valve is opened as the clamp is brought into contact with the piston-rod, substantially as described.

3. In an automobile air-pump, the combination of a fixed axle, an air-pump mounted longitudinally thereon, a rotating axle, a crown-cam mounted on said rotating axle and adapted to frictionally engage the pis-

ton-rod of the air-pump, a spring for maintaining the piston-rod in engagement with the cam when the pump is operated, a frictional clamp adapted to compress the piston-rod and hold it against the tension of the spring and away from the cam, an automobile-body mounted upon springs located between the axle and the body and adapted to vibrate thereon, elastic means connecting the body and the clamp of sufficient tension to permit of the effective application of the clamp, and to accommodate the oscillations of the body without releasing the effective frictional contact of the clamp with the piston-rod, and means for actuating the elastic connection, substantially as described.



706,052. TOBACCO-HOISTER. WILLIAM P. HENRY, Central City, Ky. Filed May 28, 1902. Serial No. 109,364. (No model.)

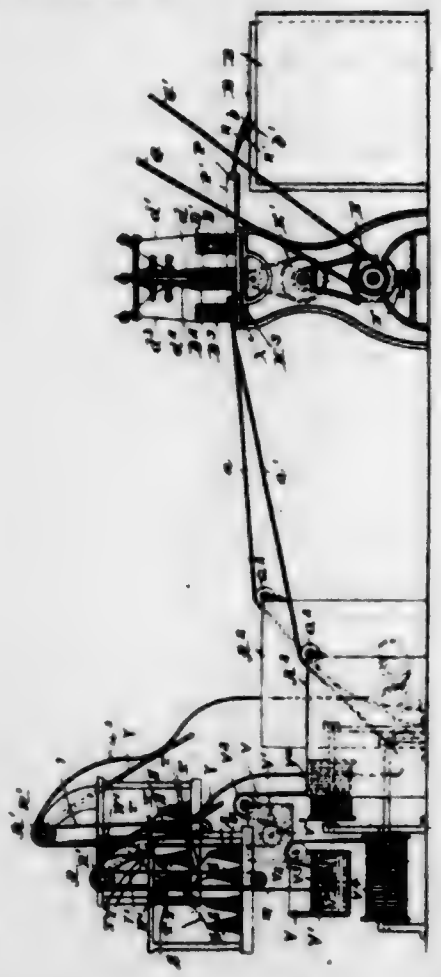
Claim.—1. In a tobacco-hoister, the combination of a staff, a pulley located at the top of the said staff, a runner engaging the staff, a bar pivotally supported upon the runner, and a hoisting-rope passing over the pulley and arranged to raise and lower the runner, substantially as described.

2. In a tobacco-hoister, the combination of a staff consisting of separable portions, a pulley located at the top of said staff, a runner engaging the staff, a bar pivotally supported upon the runner, and a hoisting-rope passing over the pulley and arranged to raise and lower the runner, substantially as described.

3. In a tobacco-hoister, the combination of a staff, a pulley located at the top of the said staff, a runner engaging the staff, a bar pivotally supported upon the said runner, the said bar being provided with means for holding a stick of tobacco, the said bar being pivoted at one side of its middle point, and a hoisting-rope passing over the pulley and arranged to raise and lower the runner, substantially as described.

4. In a tobacco-hoister, the combination of a rectangular staff, a pulley located at the top of the said staff, a runner constructed to engage the staff, a bar pivotally supported upon the said runner, the said bar being provided with means for holding a stick of tobacco, a hoisting-rope passing over the pulley and arranged to raise and lower the said runner, a movable platform having guides, and devices sliding in the said guides of the platform and constructed to hold the staff upright, substantially as described.

706,058. MEANS AND APPLIANCES FOR THE MANUFACTURE OF COVERED STRIPS OF SOFT METAL FOR ELECTRICAL OR OTHER PURPOSES. ISAAC W. HETTINGER, Philadelphia, Pa. Filed Dec. 4, 1901. Serial No. 84,632. (No model.)



Claim.—1. The conjoined means for the manufacture of covered strips of soft metal consisting of one or more braiding-machines provided with a cup beneath adapted to hold a supply of liquid cement, guides adapted to carry a continuous soft-metal strip down through said cement and thence up to and through said braiding-machine, feed-rolls adapted to pass said strip through said machine continuously, a twin-needle sewing-machine adapted to receive two of said covered soft-metal strips from said braiding machine or machines, twin guide-passages adapted to direct each strand separately beneath its appropriate needle in said machine, and suitable means for subsequently receiving said completed fabric in separate strands, substantially as described.

2. In the manufacture of flat, cemented and covered strips of soft metal, having a stitched seam through the said metal strips along the flat sides thereof, and through said coverings, along the length thereof, the combination of a multiple or twin needle lock stitch sewing-machine, with a multiple or twin guide, having separate and parallel guide-passages through the same, one for each strand of material, and adapted to deliver said strands separately, one under each needle of said machine, and above the loop-forming mechanism thereof, said needles adapted to operate simultaneously and perforate said coverings and said inclosed metal strip, and stitch the same securely together from end to end, substantially as described.

3. In the manufacture of multiple strips of flat metal, covered with coverings of fabric separately braided thereupon, a multiple-needle sewing-machine adapted to simultaneously form a lock-stitch seam along and through the flat sides of each of said strips and the covering thereof, and a guide having parallel multiple guide-passages through the same adapted to present said covered strips separately to the needle and loop-forming mechanism of said sewing-machine, and multiple guideways to deliver the

separate covered and stitched strips each to a separate receptacle therefor, substantially as described.

4. In the manufacture of soft-metal strips having braided and cemented coverings, a twin or multiple needle sewing-machine, in combination with two or more reels adapted to deliver said covered strips to the needle and loop-forming mechanism of said sewing-machine, and guide-passages, one for each of said strips, directed each to one of the needles thereof as they operate, said machine adapted to simultaneously stitch twin or multiple covered strips through said coverings and said inclosed soft-metal strips within the said coverings, substantially as described.

5. In the manufacture of soft, flat metal strips, covered with a textile fabric continuously connected to said inclosed metal strip, said cement applied in liquid form to said strips and dried in contact therewith and with said coverings, said covered and cemented strips subsequently stitched together by a continuously-sewed seam passing through the flat surfaces of said covering and metal strip, a twin or multiple needle sewing-machine, and in combination therewith a guide having parallel and twin or multiple guide-passages, one for each of a series of said strips, feed mechanism adapted to simultaneously present and deliver said strips into said sewing-machine, and simultaneously stitch each of said series, and subsequently and continuously deliver said strips separately to different and independent receptacles or holders, substantially as described.

6. In combination with two or more braiding-machines, each provided with a separate cup for holding liquid cement, and with spools of thread for forming a braided covering around a flat soft-metal strip, and with means for passing said strip through said cement and through said braider, and for applying a coating of liquid cement to said strip and immediately afterward braiding a braided covering of fabric around said wet strip, and means for feeding and drying the said strip through said machine, and for passing said strip through a sewing-machine and applying a stitched seam sewed through said covering and metal strip, means for feeding said covered strip through a sewing-machine, adapted thereto together with a guide-passage to direct said covered strip thereto, and means for subsequently delivering said completed cemented, covered and stitched strips to separate receptacles adapted therefor, and from which said strips are adapted to be cut up transversely into suitable lengths for use, substantially as described.

7. In combination with a twin or multiple needle sewing-machine, a detachable and adjustable guide for twin or multiple strips of soft metal, having parallel guide-passages through the same and directed, one passage-way to each of said needles, and exit guide-passages beyond said needles, one for each of said strips after the same have been stitched, the whole constructed to operate substantially as and for the purposes described.

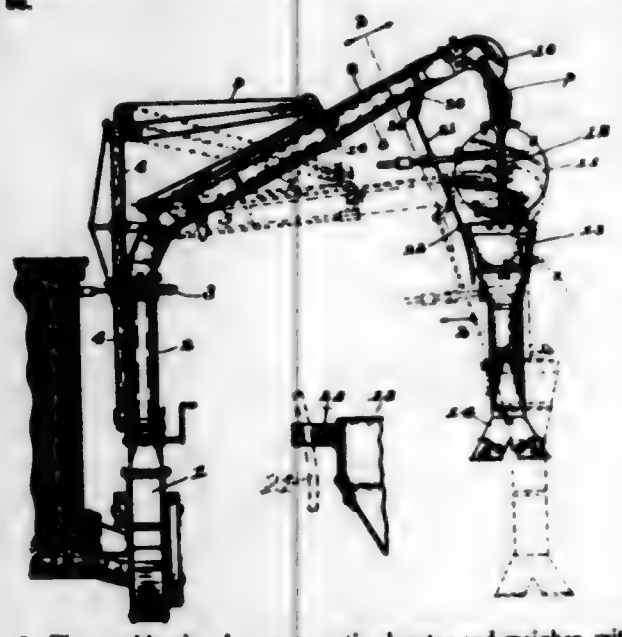
8. The means and appliances for manufacturing cemented and braid-covered strips of soft metal, consisting of a braiding-machine having cup of liquid cement, and spools of suitable thread, and means for passing a strip of soft metal successively through said cement and braider, a sewing-machine having a guide-passage adapted to direct said cemented and braided metal strip to the needle mechanism thereof, means for passing said strip through said sewing-machine and directly beneath the needle thereof, adapted to make a stitched seam through said covering and said metal, and means for taking up the finished product after passing through said sewing-machine, substantially as described.

9. The means and appliances for manufacturing cemented and braid-covered strips of soft metal, said covering and strip stitched together by a continuous lock-stitch seam, consisting of a braiding-machine having means for applying a coat of liquid cement to a covered strip passing through the same, and subsequently braiding upon it a covering of textile material, a sewing-machine having suitable guideways and feed mechanism, and adapted to pass the same therethrough and make a stitched seam through said cemented and covered metal strip, substantially as described.

10. In combination with the needle and loop-forming mechanism and feed of a twin or multiple needle sewing-machine, the detachable and adjustable parallel multiple guide-passages O^x O^z, each passage adapted to deliver a strand of covered fabric separately thereto, said fabric of soft metal covered with soft textile covering, and said sewing-machine adapted to make a separate row of stitches through each of said covered metal strips, and a corresponding series of divergent-delivery-guides, P P^z, from said needles to a receptacle or holder for each of said covered and stitched strips, substantially as described.

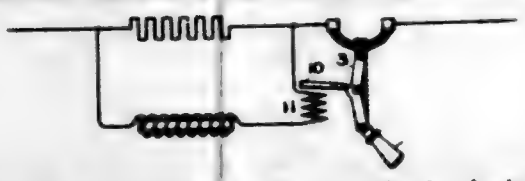
706,054. PNEUMATIC ELEVATOR AND WEIGHER. RIDGELY B. HILLIARY and CHESTER BRADFORD, Indianapolis, Ind. Filed Dec. 18, 1901. Serial No. 86,248. (No model.)

Claim.—1. The combination, in an adjustable elevator and weigher wherein the weigher apparatus is pivotally suspended to the elevating apparatus, of an adjustable brace extending from the elevating apparatus to a frame or rigid portion connected to the weigher apparatus, whereby the latter may be adjustably secured and held in position relatively to the weighing apparatus and a vertical position of said weigher apparatus thus maintained whatever the relative position of the elevator apparatus may be.



2. The combination, in a pneumatic elevator and weigher, with the adjustable elevator-pipe and the weigher apparatus suspended thereto, of a bracing apparatus consisting of a yoke 20, a brace-rod 21 connected to said yoke, a stud or eye 22 connected to the weigher apparatus frame and to which said brace-rod is connected, and a means whereby said brace-rod can be secured thereto at any desired position therein, substantially as set forth.

706,055. TIME-LIMIT CIRCUIT-BREAKER. HENRY M. HOBART, Berlin, Germany, assignor to General Electric Company, a Corporation of New York. Filed Jan. 5, 1901. Serial No. 42,260. (No model.)



Claim.—1. The combination with a circuit-breaker having a tripping-coil normally connected to the circuit upon which the circuit-breaker operates, of electroreactive means for causing the current in said tripping-coil to vary slower than the current in said circuit.

2. The combination of a divided circuit, one branch of which includes the tripping-coil of a circuit-breaker, and a device possessing inductance in series with said tripping-coil.

3. The combination of a divided circuit, one branch of which includes the tripping-coil of a circuit-breaker, and a device in series with said tripping-coil and acting to oppose variation of current but inactive during a steady condition of current.

4. A circuit-breaker comprising circuit-interrupting means, a tripping-coil, and a device possessing reactance for preventing the current in the tripping-coil from varying at the same rate as the current in the circuit upon which the circuit-breaker operates.

5. The combination of a divided circuit, one branch of which includes the tripping-coil of a circuit-breaker, and means responsive to variation of current for causing the branch including the tripping-coil to have a higher time constant than the other.

6. The combination of a divided circuit, one branch of which includes the tripping-coil of a circuit-breaker, and means dependent for its action upon variation of current for causing the branch including the tripping-coil to have a different time constant than the other.

706,056. BOTTLE. WILLIE W. HOLLAND, Brenham, Tex. Filed Apr. 18, 1902. Serial No. 103,570. (No model.)

Claim.—1. A bottle having a closed neck formed integral with the bottle, a vulnerable portion to said neck, a shield for said vulnerable portion formed integral with the neck and serving also as the mouth of the bottle, and means for filling and sealing the bottle.

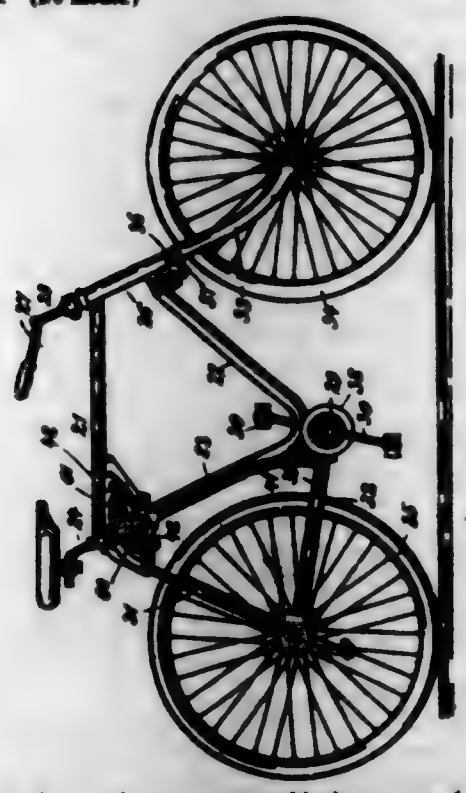
2. A bottle having a closed neck formed integral with the bottle, a vulnerable portion to said neck accessible through the mouth of the bottle, a false neck or shield for said vulnerable portion forming the mouth of the bottle and also a passage-way to conduct the broken glass from the bottle-mouth, and means for filling and sealing the bottle.

706,057. FOLDING BOX OR CASE. JOHN A. HOLLEN, Sioux City, Iowa. Filed Aug. 3, 1901. Serial No. 70,208. (No model.)

Claim.—1. A sample-case comprising two sections, one of which being smaller than the other and each having upright sides and an end portion, a strip hingedly connected to the bottoms of the sections at the open ends thereof, a flexible connection uniting the sides of the said sections, and a tape secured to the larger section, substantially as shown and for the purpose set forth.

2. A sample-case substantially as described comprising two sections, each section being formed of a bottom, sides and an end portion, a solid strip having its sides hinged to the open ends of the bottoms, flexible sections uniting the inner ends of the sides, and a tape connected to one of the sections, substantially as shown and described.

706,058. CYCLE. CHARLES L. HOBACK, New York, N. Y., assignor to Rufus H. Williams, New York, N. Y. Filed Apr. 26, 1900. Serial No. 14,373. (No model.)



Claim.—1. In a cycle, pneumatic cushioning means adapted to resist relative displacement of the seating-surface of the saddle and one of the wheels and comprising a spring and two chambers, each chamber having a movable wall, one of said walls being adapted to yieldingly resist such relative displacement in one direction, and the other wall being adapted to resist such displacement in the opposite direction, means interposed between said chambers for permitting the flow of air between said chambers in one direction, and for permitting and regulating the flow of air in the opposite direction, and means for alternately actuating said spring and producing reaction of the same by alternate movements of said walls.

2. In a cycle, pneumatic cushioning means adapted to resist relative displacement of the seating-surface of the saddle and one of the wheels, and comprising a chamber having a movable wall adapted to be actuated upon such relative displacement and two additional chambers communicating therewith, and two check-valves, one of said valves being placed at the entrance to each of said chambers, suitable return-passages being provided between the chambers between which check-valves are so inserted.

3. In a cycle, pneumatic cushioning means containing three chambers and adapted to resist relative displacement of the seating-surface of the saddle and one of the wheels, and comprising a movable wall forming part of one of said chambers and adapted to be actuated upon such relative displacement, the additional two chambers being connected with the chamber having said movable wall, two automatic valves, one of said valves being interposed between aforesaid chamber and one of the additional chambers, and the other valve being interposed between aforesaid chamber and the other additional chamber, and means for forcing one of said valves toward its seat with greater pressure than that applied to the other valve, suitable return-passages being provided between the chambers between which check-valves are so inserted.

4. In a cycle, pneumatic cushioning means comprising three chambers and adapted to resist relative displacement of the seating-surface of the saddle and one of the wheels and comprising a movable wall forming part of one of said chambers and adapted to be actuated upon such relative displacement, each of the additional two chambers being in direct communication with aforesaid chamber, and two valves, one of said valves being placed in the connecting-passage between aforesaid chamber and one of the additional chambers, and the other being placed in the connecting-passage between aforesaid chamber and the other additional chamber, suitable return-passages being provided between the chambers between which check-valves are so inserted.

5. In a cycle, pneumatic cushioning means adapted to be compressed upon relative displacements of the seating-surface of the saddle and one of the wheels, said cushioning means comprising a chamber communicating with two other chambers, an automatic valve at the inlet to each of said other chambers, said valves being adapted to open successively, suitable return-passages being provided for permitting return flow of air while said valves are in their restricted positions.

6. In a cycle, pneumatic cushioning means adapted to yieldingly resist relative displacement of the seating-surface of the saddle and one of the wheels and comprising two movable walls maintained during their movements in close contact or connection with the adjoining portions of said cushioning means, and an automatic valve in a passage between said walls for restricting flow of air in one direction and permitting freer flow in the opposite direction whereby two chambers are formed within said cushioning means, one of said walls being adapted to be forced inward and the other being adapted to be forced outward simultaneously during such a displacement, a proper passage being provided for permitting flow of air between said chambers while said valve is in its restricting position, and means for arresting such movement of one of said walls while permitting movement of the other wall.

7. In a cycle, pneumatic cushioning means adapted to yieldingly resist relative displacement of the seating-surface of the saddle and one of the wheels and comprising two movable walls maintained during their movements in close contact or connection with the adjoining portions of said cushioning means, and an automatic valve in a passage between said walls for restricting flow of air in one direction and permitting freer flow in the opposite direction whereby two chambers are formed within said cushioning means, a proper passage being provided for permitting flow of air between said chambers when said valve is in its restricting position, and means for arresting such movement of one of said walls while permitting movement of the other wall.

8. In a cycle, pneumatic cushioning means adapted to yieldingly resist relative displacement of the seating-surface of the saddle and one of the wheels and comprising two chambers each provided with a movable wall, and means interposed between said chambers for permitting the flow of air between said chambers in one direction while one of said walls is moving inward and the other is moving outward and to regulate the flow of air while said walls are moving in the opposite directions, whereby smaller quantities of air are caused to flow backward during such opposite movements of said walls than during corresponding movements in the other direction, and means for arresting such movement of one of said walls while permitting movement of the other wall.

9. In a cycle, pneumatic cushioning means adapted to yieldingly resist relative displacement of the seating-surface of the saddle and one of the wheels and comprising two chambers each provided with a movable wall, and means interposed between said chambers for permitting the flow of air between said chambers in one direction while one of said walls is moving inward and the other is moving outward and to regulate the flow of air while said walls are moving in the opposite directions, whereby smaller quantities of air are caused to flow backward during such opposite movements of said walls than during corresponding movements in the other direction, and adjustable means for arresting such movement of one of said walls while permitting movement of the other wall.

10. In a cycle, pneumatic cushioning means adapted to yieldingly resist relative displacement of the seating-surface of the saddle and one of the wheels and comprising two chambers each provided with a movable wall, and means interposed between said chambers for permitting the flow of air between said chambers in one direction while one of said walls is moving inward and the other is moving outward and to regulate the flow of air while said walls are moving in opposite directions, whereby smaller quantities of air are caused to flow backward during such opposite movements of said walls than during corresponding movements in the other direction, and means for adjusting the extent of the movement of one of said walls prior to the movement of the other wall.

11. In a cycle, pneumatic cushioning means closed to the atmosphere and having an outer movable wall adapted to be actuated upon relative displacement of the seating-surface of the saddle and one of the wheels, and a continuous movable wall inclosed by said cushioning means and having its edges fixedly secured to the walls of said cushioning means, whereby the same are divided into two non-communicating chambers.

12. In a cycle, pneumatic cushioning means closed to the atmosphere and having an outer flexible wall adapted to be actuated upon relative displacement of the seating-surface of the saddle and one of the wheels, and a flexible wall inclosed in said cushioning means, whereby the same are divided into two non-communicating chambers.

13. In a cycle, the combination with the frame, of pneumatic cushioning means having an outer movable wall, adapted to be actuated upon relative displacement of the seating-surface of the saddle and one of the wheels, a continuous, movable wall inclosed by said cushioning means and having its edges in continuous contact with the walls of said cushioning means, whereby the same are divided into two chambers, and an inflation-valve for each of said chambers.

14. In a cycle, pneumatic cushioning means comprising a rigid casing and a movable wall adapted to yieldingly resist relative displacement of the seating-surface of the saddle and one of the wheels, and a movable wall within said cushioning means and having its edges in fixed contact with such rigid portion, whereby the cushioning means are divided into two chambers.

15. In a cycle, pneumatic cushioning means closed to the atmosphere and having a rigid casing and a movable wall adapted to yieldingly resist relative displacement of the seating-surface of the saddle and one of the wheels, and a flexible wall inclosed within and fixedly attached to the walls of said cushioning means, whereby the same are divided into two chambers.

16. In a cycle, the combination with the frame, of a pneumatic cushion having a movable wall adapted to be actuated upon relative displacement of the seating-surface of the saddle and one of the wheels, another pneumatic cushion having a movable wall adapted to be actuated upon relative displacement of the seating-surface of the saddle and another wheel and a continuous, movable wall between said cushions having its edges in continuous contact therewith and adapted to be actuated upon relative changes of pressures within said cushions.

17. In a cycle, the combination with the frame, of a pneumatic cushion having a movable wall adapted to be actuated upon relative displacement of the seating-surface of the saddle and one of the wheels, another pneumatic cushion having a movable wall adapted to be actuated upon relative displacement of the seating-surface of the saddle and another wheel, and a flexible wall forming part of each of said cushions adapted to be deflected upon relative changes of pressures within said cushions.

18. In a cycle, the combination with the frame, of a pneumatic cushion having a movable wall adapted to be actuated upon relative displacement of the seating-surface of the saddle and one of the wheels, another pneumatic cushion having a movable wall adapted to be actuated upon relative displacement of the seating-surface of the saddle and another wheel, a continuous, movable wall between said cushions and having its edges in continuous contact therewith and adapted to be actuated upon relative changes of pressures within said cushions, and an inflation-valve for each of said cushions.

19. In a cycle, the combination with a sectional frame, of a pneumatic cushion having a rigid casing and a movable wall adapted to be actuated upon relative displacement of the seating-surface of the saddle and one of the wheels, another pneumatic cushion having a rigid casing and a movable wall adapted to be actuated upon relative displacement of said seating-surface and another wheel, and a continuous, movable wall between said cushions having its edges in continuous contact with rigid portions of both said cushions and adapted to be actuated upon relative changes of pressures within said cushions.

20. In a cycle, the combination with a tubular sectional frame and the running-gear, of pneumatic cushioning means adapted to be compressed upon relative displacement of two of the frame-sections, tubing of one of the frame-sections forming portion of said cushion, and a continuous flexible wall within said tubing and fixedly attached thereto whereby said cushioning means are divided into two compartments.

21. In a cycle, the combination with a sectional frame, of cushioning means interposed between said sections and comprising a flexible diaphragm constructed in the form of a cup and having a flange protruding outside of its walls, a base in contact with the outer surface of said flange and provided with a suitable contact portion adapted to engage with one of the frame-sections, and means for securing said flange to said protruding portion of the diaphragm.

22. In a cycle, the combination with a sectional frame, of cushioning means interposed between said sections and comprising a flexible diaphragm constructed in the form of a cup and having a flange protruding outside of its walls, a base in contact with the outer surface of said flange and provided with a suitable contact portion adapted to engage with one of the frame-sections, an annular disk on the other side of said flange, and means for attaching said disk to said base outside of said diaphragm.

23. In a cycle, the combination with a sectional frame, comprising a seat-section, and a wheel-section articulated thereto, of cushioning means interposed between said sections, the wheel-section extending forward beyond and rearward of the diagonal or down tube of the seat-section, the forward extension being in the form of a yoke 42 in a substantially vertical plane, said yoke being placed laterally and at the same elevation with reference to such portion of the seat-section, and cushioning means interposed between said diagonal tube and the branches of said yoke.

24. In a cycle, the combination with a sectional frame having the seat-section comprising a diagonal or down tube and the upper main tube articulated to the rear-wheel section, the latter comprising the lower and the upper rear fork and a brace extending upward from the lower forward portion of said wheel-section, and a connecting device 42 between the upper portions of said brace and said upper fork extending forward beyond the diagonal or down tube, said connecting device being placed laterally with reference to the seat-section, and means for guiding said connecting device along said diagonal tube and said upper main tube.

25. In a cycle, the combination with a sectional frame having the seat-section articulated to the rear-wheel section, the latter comprising the lower and the upper rear fork and a brace extending upward from the lower forward portion of said wheel-section, and a substantially O-formed connecting device 42 between the upper portions of said brace and said upper fork extending forward beyond and rearward of the diagonal or down tube, said connecting device being placed laterally with reference to the seat section, of the seat section, and cushioning means interposed between said two sections and inserted within said connecting device forward and backward of said down-tube.

26. In a cycle, the combination with a sectional frame having the seat-section articulated to the rear-wheel section, the latter comprising the lower and the upper rear fork and a brace extending upward from the lower forward portion of said wheel-section and connected to said upper fork, and means for guiding said sections one upon the other at three points placed in substantially the same vertical plane parallel with the longitudinal central plane of the cycle and out of line with each other.

27. In a cycle, the combination with a sectional frame having the seat-section articulated to the rear-wheel section, the latter comprising the lower and the upper rear fork and a brace attached to the lower forward portion of said wheel-section in the rear of the crank-shaft, and means for connecting it to the upper portion of said upper fork, the portion of said brace between its points of attachment being placed substantially parallel with the down-tube of the seat-frame and lateral thereto.

28. In a cycle, the combination with a sectional frame, one of the frame-sections being articulated to another section, of cushioning means interposed between said sections, and a friction-roller with suitable axle between said sections, said axle being placed parallel with the axle to which the frame-sections are articulated, a guiding-surface being provided on one of said sections along which said roller travels longitudinally, while revolving around its axis.

29. In a cycle, the combination with a sectional frame, of cushioning means interposed between relatively movable sections of the frame, a friction-roller with suitable axle between said sections, a guiding-surface being provided on one of said sections along which said roller travels longitudinally while revolving around its axis, and an elastic tension device for enforcing contact between said roller and the other frame-section.

30. In a cycle, the combination with a sectional frame, of a rigid hollow casing detachably secured to one of the frame-sections and provided with a multiplicity of outlets, different cushioning means connected with said outlets and adapted to be compressed upon relative displacements of sections of the frame, an automatic valve in each of said outlets whereby flow of air is restricted by it in one direction and freer flow is permitted in the opposite direction, and means for permitting flow between said rigid hollow casing and the cushioning means connected with said outlets while the corresponding valves are in their restricting positions.

31. In a cycle, the combination with a sectional frame comprising

a seat-section and a wheel-section, of a rigid casing detachably secured to the diagonal or down tube of the seat-section and extending forward and backward of the same, pneumatic cushioning means attached to said casing forward and backward of said tube, and adjusted to contact with portions of the wheel-frame, a connecting-passage being provided between said cushioning means within said casing, an automatic valve in said passage for restricting flow of air in one direction and for permitting freer flow in the opposite direction, and means for permitting flow of air between said cushioning means while said valve is in its restricting position.

32. In a cycle, the combination with a sectional frame comprising two relatively movable sections, of a hollow rigid U-shaped casing detachably secured to one of said sections, and a pneumatic cushion mounted upon said casing and connecting with its interior and adapted to contact with the other frame-section.

33. In a cycle, the combination with a sectional frame, of a hollow rigid U-shaped casing detachably secured to one side of and partly encircling one of the tubes of one of the frame-sections, and a bracket connecting the branches of said U-shaped casing, thereby entirely surrounding said tube, and cushioning means mounted upon said casing and connecting with its interior and adapted to contact with the other frame-section.

34. In a cycle, the combination with a sectional frame, of an axle on one of the frame-sections, and an arc-shaped casing forming part of another frame-section and revolubly mounted on said axle and adapted to be attached to and detached from said axle by moving it at right angles thereto, a shoe detachably secured to the end of one of the branches of said arc-shaped casing, and a projection on said axle adapted to engage with said shoe.

35. In a cycle, the combination with a sectional frame, of an axle on one of the frame-sections, an arc-shaped rigid casing revolubly mounted thereon and forming part of another frame-section, and a retaining device movable with reference to said casing and held against its outer surface for retaining it in proper position with reference to said axle.

36. In a cycle, the combination with a sectional frame, of an axle on one of the frame-sections, an arc-shaped rigid casing revolubly mounted thereon and forming part of another frame-section, and a roller with suitable axle and bearings in contact with the outer surface of said casing for the purpose of retaining it in proper position with reference to said axle, said bearings being fixedly attached to said axle.

37. In a cycle, the combination with a sectional frame, of an axle on one of the frame-sections, a rigid casing revolubly mounted thereon and forming part of another frame-section, and a series of rollers around the outer periphery of said casing having their bearings rigidly attached to said axle and adapted to guide said casing.

38. In a cycle, the combination with a sectional frame, of an axle on one of the frame-sections, a casing revolubly mounted thereon and forming part of another frame-section, a guide-roller interposed between said casing and the section carrying said axle, and means for adjusting the position of the axle of said guide-roller with reference to aforesaid axle.

39. In a cycle, the combination with a sectional frame, of an axle on one of the frame-sections, an arc-shaped casing revolubly mounted thereon and forming part of another frame-section, and a brace between the branches of said arc-shaped casing and fixedly attached thereto, whereby a sleeve is formed around said axle.

40. In a cycle, the combination with a sectional frame, of an axle on the frame-section comprising the lower rear fork, an arc-shaped casing revolubly mounted on said axle and forming part of another frame-section, and a brace rigidly attached to both branches of said arc-shaped casing and placed between the prongs of said fork, whereby a sleeve is formed around said axle.

41. In a cycle, the combination with a sectional frame, of an axle on one of the frame-sections, a casing revolubly mounted with reference to said axle, and means for adjusting and confining said casing in varying positions with reference to the longitudinal direction of said axle.

42. In a cycle, the combination with a sectional frame, of pneumatic cushioning means interposed between its sections, an axle on one of said sections, a casing revolubly mounted with reference to said axle, a pneumatic cushion between axle and casing, said casing being adapted to slide along said cushion while revolving with reference to the axle, and a connecting-passage between said cushion and aforesaid cushioning means.

43. In a cycle, the combination with a sectional frame, of pneumatic cushioning means having an inflation-valve interposed between its sections, a casing revolubly mounted with reference to said axle, a pneumatic cushion with an independent inflation-valve between axle and casing, said casing being adapted to slide along said cushion while revolving with reference to the axle, a connecting-passage between said cushioning means and said cushion, and a stop-cock in said passage between said inflation-valves.

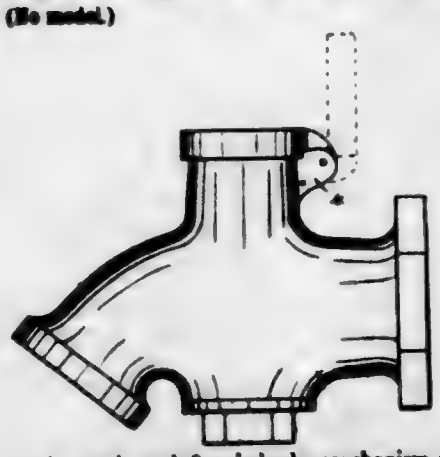
44. In a cycle, the combination with a sectional frame, of an axle on one of the frame-sections, a casing revolubly mounted thereon and forming portion of another frame-section, a rubber cushion interposed between axle and casing and seated upon one of said parts, and a series of metal contact-points attached to said cushion and adjusted to contact at intervals with the relatively movable portion of the other one of said parts, said contact-points forming portions of a continuous strip of metal.

45. In a cycle, the combination with a sectional frame, of an axle on one of the frame-sections, a casing revolubly mounted thereon and forming portion of another frame-section, an arc-shaped rubber cushion seated within a trough upon the circumference of said axle, and a continuous metallic band having its interior surface extending from the end surfaces of said cushion around the exterior surface of the same, and having its exterior surface contacting with the interior surface of said relatively movable casing.

46. In a cycle, the combination with a sectional frame, of an axle on the rear-wheel section, a casing revolubly mounted thereon and forming portion of the seat-section, the down-tube and the lower main tube of the seat-section being made continuous in a curve which is convex where they are joined to said casing, a depression in said casing for seating therein such curved portions of said tubes, and means for attaching the same to said casing.

47. In a cycle, the combination with a sectional frame, of an axle on the rear-wheel section, a casing revolubly mounted thereon and forming portion of the seat-section, the down-tube and the lower main tube of the seat-section being made a continuous tube, and a yoke for joining said continuous tube and said casing together and extending around and attached to the greater portion of the periphery of said tube and along portion of the outer surface of and along the sides of said casing.

706,059. **ANGLE-COCK FOR AIR-BRAKE MECHANISM.** MARTIN L. HOUDEK, Fort Wayne, Ind. Filed Feb. 15, 1902. Serial No. 94,173. (No model.)



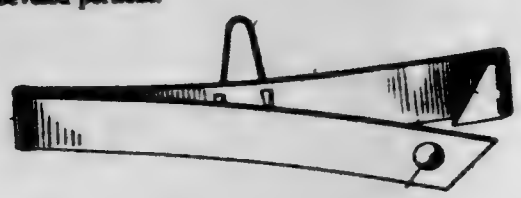
Claim.—1. An angle-cock for air-brake mechanism consisting of a hollow casting having a central upright chamber provided with opposite openings or air-ports; a rotary valve loosely mounted in said chamber, having a diametric opening adapted to register with the said air-ports when the valve is open, and provided upon its upper end with an angular extension which is contained within said chamber and which is adapted to indicate whether the said valve is open or closed; means for limiting the valve to a quarter-turn; and detachable means for rotating said valve to either limit of its adjustment; and means for normally closing said valve-chamber.

2. The combination in an angle-cock for air-brakes, of a hollow valve-casing having a screw-threaded opening in each end thereof, and having a central upright open-ended valve-chamber communicating with the interior of the casing by means of lateral ports, as shown, and provided upon its inner face with a pair of opposite lateral lugs adapted to limit the rotation of the contained valve; an inlet-valve rotatably mounted in said chamber, having a diametric opening adapted to register with the said lateral ports as described, and provided with an angular extension upon the upper end thereof which is at all times within the said casing; and a hinged lid closing the upper end of said chamber.

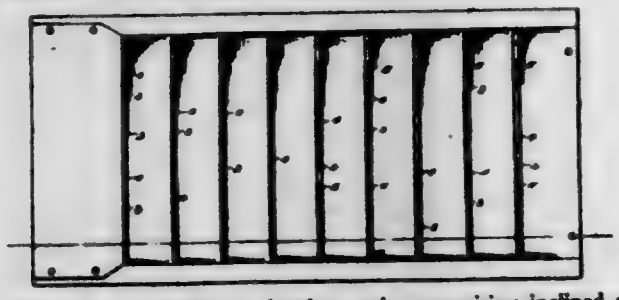
3. In an angle-cock a valve-casing having an inlet-port in each end thereof, and a central open-ended valve-chamber provided with opposite lateral ports, and with means for limiting the rotation of the contained valve; an inlet-valve rotatably mounted in said chamber, and having an opening therein adapted to register with the said ports when the valve is open; means for normally concealing said valve in said chamber; detachable means for operating said valve and the described means for determining by inspection whether the said valve is open or closed.

706,060. **TROUSERS-HANGER.** JAMES H. HOWE, Buffalo, N. Y. Filed May 11, 1900. Serial No. 16,303. (No model.)

Claim.—A trousers-hanger, made of a strip of spring metal, having its ends oppositely beveled, and at one end bent outwardly and then inwardly so that it extends inwardly a short distance beyond the loop thus formed, and being bent near its center outwardly and then inwardly so that its opposite end extends slightly beyond the first-named end, the two ends thus formed being capable of slightly overlapping each other throughout their beveled portions.



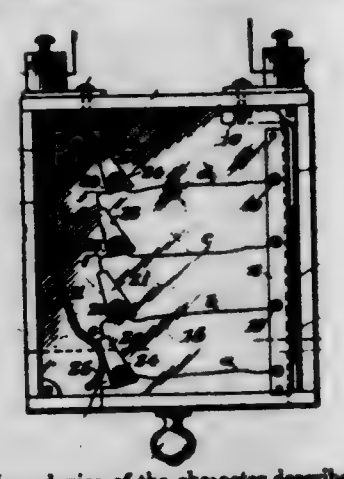
706,061. RIDDLE. EDWARD HUBER, Marion, Ohio. Filed Dec. 30, 1901. Serial No. 87,069. (No model.)



Claim.—1. A riddle for cleaning grain, comprising inclined slats, bars extending from the lower edge of each slat to the upper edge of the preceding slat, and projections between the bars, extending upward from the lower edge of each slat into the opening formed between the adjacent bars, substantially as described.

2. A riddle for cleaning grain, comprising inclined slats, a plurality of substantially upright bars extending from the lower edge of each slat to the upper edge of the preceding slat, thereby forming openings or spaces, and projections extending up centrally from the lower edges of the slats into said openings or spaces, whereby there are formed a plurality of relatively narrow openings above the edges of the slats to the height of the projections, and a plurality of relatively wider openings above the same and above the projections, substantially as described.

706,062. MAGAZINE FUSE-BOX. HARRY L. HUNT and WILLIAM R. MOON, Traverse City, Mich. Filed Nov. 5, 1901. Serial No. 81,254. (No model.)

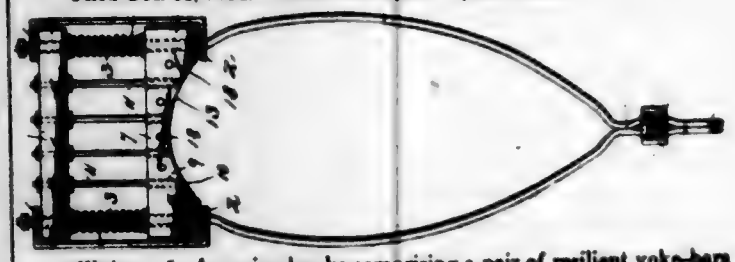


Claim.—1. In a device of the character described, the combination with a fuse-box, of a pair of circuit-terminals, one of which has the form of a spring, a magazine-slide mounted in the fuse-box and provided with a series of notches at one side disposed for engagement with the end of the spring-terminal, individual contact-plates located within said notches, fuses extended from said individual contact-plates to the opposite side of the magazine-slide, and means for effecting electrical connection between the other circuit-terminal and the ends of the fuses at the side of the slide opposite the individual contact-plates.

2. In a device of the character described, the combination with a fuse-box, and circuit-terminals therein in the form of springs, of a magazine formed in one side face thereof with a series of notches each defined by an inclined wall and an abruptly-curved wall, individual contact-plates imposed upon the several inclined walls, fuses extending from said plates to the opposite side of the magazine, and a continuous contact-plate connected to the several fuses and disposed in sliding contact with the circuit-terminal located at the side of the magazine opposite the individual contact-plates.

3. In a device of the character described, the combination with a fuse-box, and a pair of circuit-terminals in the form of springs, one of which has its free extremity curved, of a magazine-slide mounted in the fuse-box and provided with a series of notches at one side disposed for engagement with the curved end of the adjacent circuit-terminal, individual contact-plates located within said notches, fuses extending from said individual contact-plates to the opposite side of the magazine, and a continuous contact-plate connected to the ends of the fuses opposite the individual contact-plates and disposed in constant sliding engagement with the other circuit-terminal.

706,063. ANIMAL-POKE. HIRAM E. IRISH, Morille, Iowa. Filed Dec. 31, 1901. Serial No. 87,043. (No model.)



Claim.—1. An animal-poke comprising a pair of resilient yoke-bars with lower hooked terminals, a clamp surrounding said yoke-bars adjacent their hooked terminals for preventing said bars from separating, an upper vertically-movable device with which said yoke-bars engage, and a series of vertically-disposed movable rods having lower pointed ends and arranged in planes parallel with the upper portions of the yoke-bars and carried by the said movable device, said rods being actuated by the yoke-bars.

2. A poke comprising a head-bar carrying a plurality of vertically-disposed movable pointed rods, a guide-bar below the head-bar and through which the said rods are adapted to movably extend, springs interposed between the said bars to restore the latter and the rods to normal position, and resilient yoke-bars movably passing through the opposite extremities of both the head-bar and guide-bar and having lower laterally-extending hooked terminals.

3. A poke comprising a head-bar carrying a plurality of vertically-disposed movable pointed rods, a guide-bar below said head-bar and through which said pointed rods are adapted to extend, other pointed rods immovably secured to the guide-bar and extending rearwardly from the latter in horizontal planes, springs interposed between said bars to restore the parts to normal position, and yoke-bars extending through the said head and guide bars and having hooked terminals, the head-bar being vertically movable on the upper extremities of the yoke-bars.

706,064. HYDROCARBON-BURNER. WILLIAM R. JEAVONS, Cleveland, Ohio. Filed Feb. 24, 1902. Serial No. 95,148. (No model.)

Claim.—1. A vaporizing-trough, and a conduit for supplying oil thereto internally exposed at its top and open to the lower portion of the trough and provided with a vapor-outlet at its upper portion, substantially as described.

2. A vaporizing-trough having seats for a combustion-chamber, an oil-supplying conduit fixed to the said trough and open at its top, and having an extension projecting above said seats and provided with an opening for the overflow of vapor above the plane of said seats, substantially as described.

3. The vaporizing-trough having seats for a combustion-chamber, an oil-supplying conduit affixed to the said trough and extending to a plane above said seats and open at its top and in open relation to the trough below said seats, and having a vapor-overflow opening above said seats, substantially as described.

4. A vaporizing-trough having seats for burner-tubes on its walls, and a double-walled conduit to supply oil to said trough having its interior exposed from the top and provided with a stem to connect with an oil-supply pipe, and having a vapor-overflow opening at its top portion above the seats for the burner-tubes, substantially as described.

5. The oil and vaper trough and a substantially U-shaped oil-supply conduit affixed thereto at its ends and having outlets at its bottom and near its top, and the opening for supplying oil to said conduit arranged on a plane slightly above the bottom of the conduit, substantially as described.

6. An oil and vaper trough and an oil-supply tank having means for maintaining a constant oil-level therein, a conduit open along its top extending from side to side of the trough and attached at its ends to the inner wall thereof, and provided with an oil-passage from its lower portion to the lower portion of the trough, and the said conduit having an opening above the said oil-level and on a lower plane than its top edges for the escape of vaper, substantially as described.

706,065. WINDOW BRACE AND FASTENER. OREN J. JENKS, Wausau, Wis. Filed Apr. 3, 1902. Serial No. 101,272. (No model.)

Claim.—In a window-fastener the combination of a bar formed of two sections, which are pivotally connected to form a continuous bar, one of the said sections being slotted, and a thumb-nut passing through the slot and engaging the opposite section to form the said pivot, the other section of the bar having a series of notches formed therein, a lug or projection formed upon the end of the said slotted section and adapted for engagement with the said notches, a bracket carried by the window and secured to the free end of the notched bar, and a bracket secured to the window-sill and pivotally connected to the slotted bar, and a latch carried by the bracket that is secured to the window and adapted for engagement with the bracket upon the sill when the window is closed, substantially as and for the purpose set forth.

706,066. RULING DEVICE. BRAGG H. JOY, Chicago, Ill. Filed Dec. 16, 1900. Serial No. 39,950. (No model.)

Claim.—1. A ruling device comprising a holder, a single ruling-strip secured to one side of the lower edge of the holder, and a running-surface on the holder at the side opposite the ruling-strip, substantially as described.

2. A ruling device comprising a holder, a single ruling-strip fastened to the lower edge of the holder at one side thereof, and means on the holder at the side opposite the ruling-strip adapted to engage a surface to permit the ruling-strip to be slid thereover free from contact therewith, substantially as described.

3. A ruling device comprising a holder, a runner at one side of the holder adapted to engage and be slid over a surface, and a single ruling-strip secured to the edge of the holder at a point a sufficient distance away from the runner to be free from contact with the surface engaged by the runner when the runner is operated, substantially as described.

4. A ruling device comprising a holder, a ruling-strip, an attaching-flange on said strip secured to the edge of the holder at a point slightly short of one side thereof, and a runner on the holder at the side adjacent the flange of the strip, substantially as described.

5. A flexible ruling-strip having a substantially vertical side and a beveled side meeting to constitute a reinforced ruling edge, substantially as described.

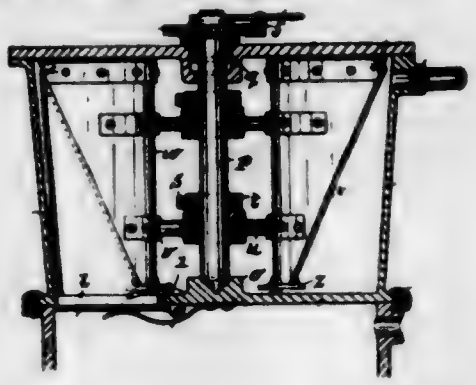
6. An article of manufacture comprising a holder, a runner at one side of the holder adapted to engage and be slid over a surface, and marking means secured to the holder in a manner to be free from contact with the surface engaged by the runner when the runner is operated, substantially as described.

7. As a new article of manufacture, a holder, a bearing at one edge of said holder upon which the same may be operated, and marking means secured to the surface of the holder at a point remote from said bearing, substantially as and for the purpose described.

8. As an article of manufacture, a holder, a bearing at one edge of said holder upon which the same may be operated, a single ruling-strip, and means securing said strip to the surface of the holder at a point remote from said bearing, substantially as and for the purpose described.

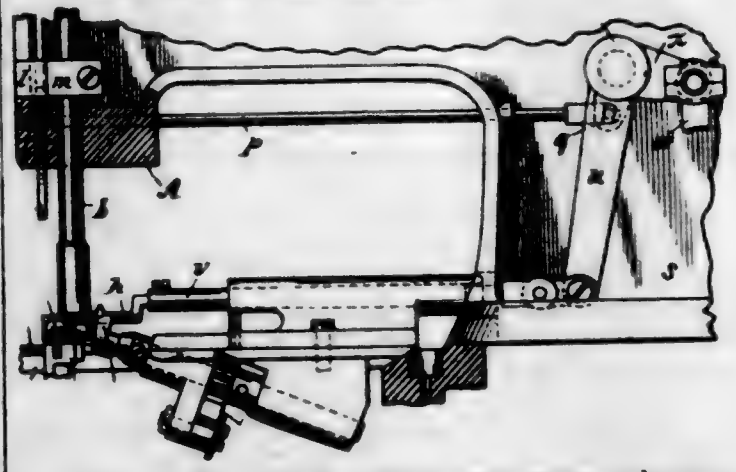
706,067. ACETYLENE-GAS GENERATOR. ARTHUR KARG, Paterson, N. J. Filed Jan. 4, 1902. Serial No. 88,285. (No model.)

Claim.—1. In an acetylene-gas apparatus, a carbid-holder consisting of a receptacle or body portion open at the top and also opening downwardly, and a closure controlling the lower opening of said receptacle hinged thereto near the upper end of said opening, said closure being normally disposed at an incline, substantially as described.



2. In an acetylene-gas apparatus, a carbid-holder open at the top and having one of its walls hinged near the upper end of said holder and extending at an incline across the same to form a closure therefor, in combination with means for maintaining said wall in its closed position, substantially as described.

706,068. PRESSER-FOOT-LOCKING MECHANISM FOR SEWING-MACHINES. HERMANN A. KLEMM, New York, N. Y. Filed Sept. 9, 1901. Serial No. 74,727. (No model.)



Claim.—1. The combination with the looper, presser, and presser-lifter, said looper having means for working the same within and transversely of the range of the presser-foot, of the locking-rod and means for operating the same synchronously with the looper, said rod automatically locking the lifter while the looper is in the range of the presser-foot, and unlocking said lifter when the looper retires out of range of the presser-foot.

2. The combination with the looper, presser, and presser-lifter, said looper having means for working the same within and transversely of the range of the presser-foot, means for automatically locking the presser-foot when the looper is within the range of said presser-foot and unlocking the same when the looper is out of the range of the presser-foot.

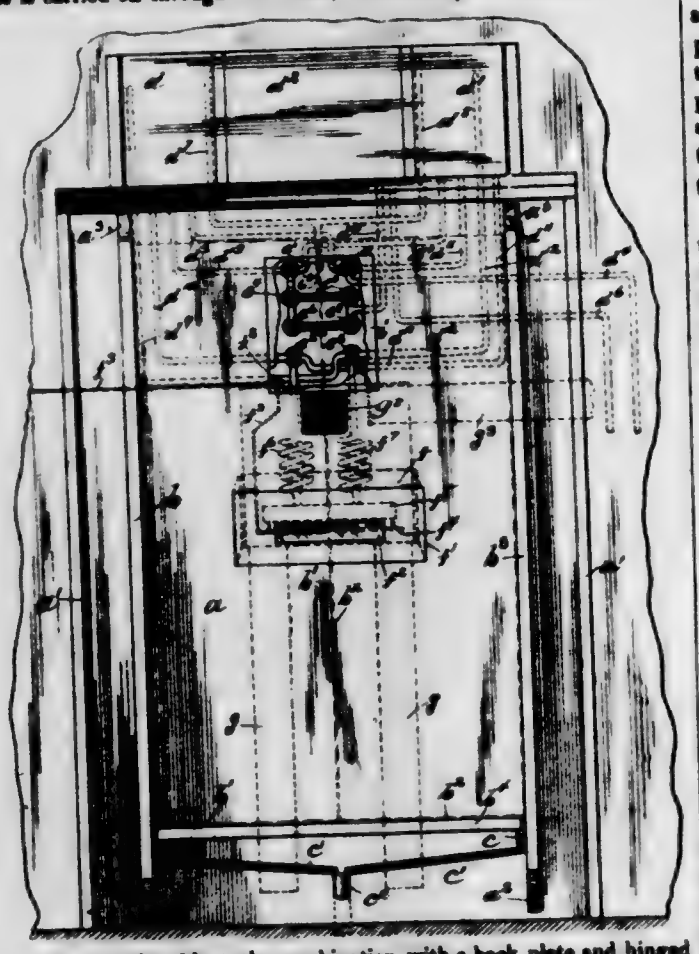
706,069. FOLDING BATH-CABINET. BURTON D. KNICKERBOCKER, Chicago, Ill. Filed June 22, 1900. Serial No. 721,227. (No model.)

Claim.—1. In a bath-cabinet, the combination with a stationary back plate, of hinged bottom, side, and front plates adapted to be folded into compact form against said back plate when not in use and to be opened when in use to form an inclosure having a bottom, side plates, and swinging doors, a drain-pipe carried by said stationary back plate, and eaves or troughs secured to the back and side plates and communicating with said drain-pipe for carrying the water from the surfaces of the bottom, back, side and front plates, substantially as described.

2. In a bath-cabinet, the combination with a back plate, of hinged bottom, side and front plates, a drain-pipe mounted upon said back plate and a series of communicating troughs mounted upon said side and back plates below the edges of said bottom plate and communicating with said drain-pipe, the front edge of said bottom plate being adapted to rest upon the troughs secured to the said side plates, substantially as described.

3. In a bath-cabinet, the combination with a back plate and hinged bottom, side and front plates, said bottom plate being provided with an upwardly-projecting ridge at the forward edge, rearwardly-inclined troughs mounted upon said side plates beneath the side edges of said bottom plate, and adapted to swing with said side plates, a drain mounted upon said back plate, and inclined troughs mounted upon said back plate communicating with the troughs on said side plates and with said drain,

whereby the water from the surfaces of said bottom, back, side and front plates is carried off through said drain, substantially as described.



4. In a bath-cabinet, the combination with a back plate and hinged bottom, side and front plates, of a fire-box or heating-chamber mounted upon said back plate, a cold-air duct carried upon said back plate and communicating with said heating-chamber and a hot-air outlet opening into the space included within the side and front plates of said cabinet, substantially as described.

5. In a bath-cabinet, the combination with a back plate and hinged bottom, side and front plates, of a fire-box or heating-chamber, mounted upon said back plate, a cold-air duct carried upon said back plate and communicating with said heating-chamber, a hot-air outlet extending from said chamber to the interior of said cabinet, and a hot-air outlet extending from said chamber to the exterior of said cabinet and provided with a valve or damper, substantially as described.

6. A folding bath-cabinet comprising a back plate secured to the wall of the room in which the cabinet is placed, a heating-coil carried upon said back plate, a hot and cold water tank, mounted at the upper end of said back plate, suitable pipes between the coil and tanks, a shower-bath attachment extending forward from the back plate and suitable connections from said tank and heating-coil to said attachment, bottom and side plates hinged to said back plate and adapted to fold up into compact form, said side plates being hinged at some distance from the side edges of said plates, one of said side plates being adapted to fold outside the other plates and to form the entire unbroken front of the cabinet when closed, and members a' at the side edges of the back plate to form the sides of the closed cabinet, substantially as described.

7. In a bath-cabinet, the combination with the back plate and the hinged bottom, side and front plates, of a heating-coil mounted upon said back plate, means to heat said coil, a pair of hot-water tanks carried at the upper end of said back plate, suitable pipes extending between said heating-coil and each of said tanks, and valves whereby either of said tanks may be connected with the heating-coil, substantially as described.

8. In a bath-cabinet, the combination with a back plate and hinged bottom, side and front plates, of a heating-chamber mounted upon said back plate and provided with suitable inlet and outlet air-passages, a heating-coil mounted within said heating-chamber, a hot-water tank mounted upon said back plate and suitable pipes and valves between said hot-water tank and said heating-coil, substantially as described.

9. In a bath-cabinet, the combination with a back plate and hinged bottom, side and front plates, of a heating-coil mounted on said back plate, a hot-water tank and a cold-water tank mounted upon said back plate at the upper end thereof and connected with said coil, a suitable valve between the hot-water tank and the heating-coil, a water-supply exit mounted upon said back plate, pipes extending between the same and said tanks, and a pair of valves, one for controlling the flow of water from the hot-water tank and the other for controlling the flow of water from the cold-water tank, substantially as described.

10. In a bath-cabinet, the combination with a back plate, and hinged bottom, side and front plates, of a heating-coil mounted on said back plate, a cold-water tank and a pair of hot-water tanks mounted upon said back plate and connected with said coil, suitable valves between the hot-water tanks and the heating-coil a water-supply exit mounted upon said back plate, a valve for connecting one or the other of said hot-water tanks to supply water to said supply-exit, and a pair of valves, one for controlling the supply of water from the cold-water tank, and the other for controlling the supply of water from the hot-water tank, substantially as described.

11. In a bath-cabinet, the combination with a back, of hinged bottom, side and front plates, a heating-coil mounted upon the back and a heating-chamber therefor, a hot and a cold water tank at the upper end of the cabinet, pipes extending from said tanks to the coil and to the cabinet, a faucet-board carried by the back, and a plurality of faucets mounted on said board and controlling the flow of water through said pipes substantially as described.

706,070. JOINT FOR PILASTERS, PILLARS, POSTS, &c. WILLIAM KOPP, Louisville, Ky. Filed May 9, 1902. Serial No. 106,660. (No model.)

Claim.—1. In a new and useful joint of the character described, the combination with a pair of pieces to be united, of a pair of long meeting faces between the same, with a series of short segregated slots placed one above another in a meeting face and a series of headed projections separable from their meeting face and placed one above another and mating said slots, with all the slots and headed projections placed intermediate of the side edges of the meeting faces, enlarged openings for the slots, with a front wall for each side of each of the slots left integral with the wood of the piece and extending rearwardly toward the seating end of the slot, a rear wall for each slot left integral with the wood of the piece, with the slots and openings cut directly into the wood of the piece and entirely surrounded by the wood left integral with the piece at the sides, ends and rear of the slots and openings, said slots, openings and headed projections and securing means for the latter visible only at said meeting faces when the pieces are separated, with all the headed projections separable from their meeting face adapted to enter the said enlarged openings simultaneously by the movement of one meeting face at right angles to the other and thereby bringing all the slots and projections into vertical alinement, and drawing the two meeting faces together uniformly throughout their length by the further movement of a meeting face longitudinally of the other and thereby entirely hiding all parts of the securing means and fastenings therefor from all sides.

2. In a new and useful joint of the character described, the combination with a pair of pieces to be united, of a pair of long meeting faces between the same, with a series of short segregated slots placed one above another in a meeting face and a series of headed projections separable from their meeting face and placed one above another and mating said slots, with all the slots and headed projections placed intermediate of the side edges of the meeting faces, enlarged openings for the slots, with a front wall for each side of each of the slots left integral with the wood of the piece and extending rearwardly toward the seating end of the slot, a rear wall for each slot left integral with the wood of the piece, with the slots and openings cut directly into the wood of the piece and entirely surrounded by the wood left integral with the piece at the sides, ends and rear of the slots and openings, said slots, openings and headed projections and securing means for the latter visible only at said meeting faces when the pieces are separated, beading for each of said pieces extending longitudinally thereof, with the receding face of said beading next the meeting face of each piece receding from the outer face of the piece toward said meeting face and with the receding faces of beads of both pieces uniting and forming the depression between two beads when the pieces are united for obscuring the meeting line between the pieces when united, with all the headed projections separable from their meeting face adapted to enter the said enlarged openings simultaneously by the movement of one meeting face at right angles to the other and thereby bringing all the slots and projections into vertical alinement, and drawing the two meeting faces together uniformly throughout their length by the further movement of a meeting face longitudinally of the other and thereby entirely hiding all parts of the securing means and fastenings therefor from all sides.

706,071. SPOKE-TIGHTENER. VALCOURE J. LA BAUVE, Houston, Tex. Filed Nov. 23, 1901. Serial No. 83,416. (No model.)

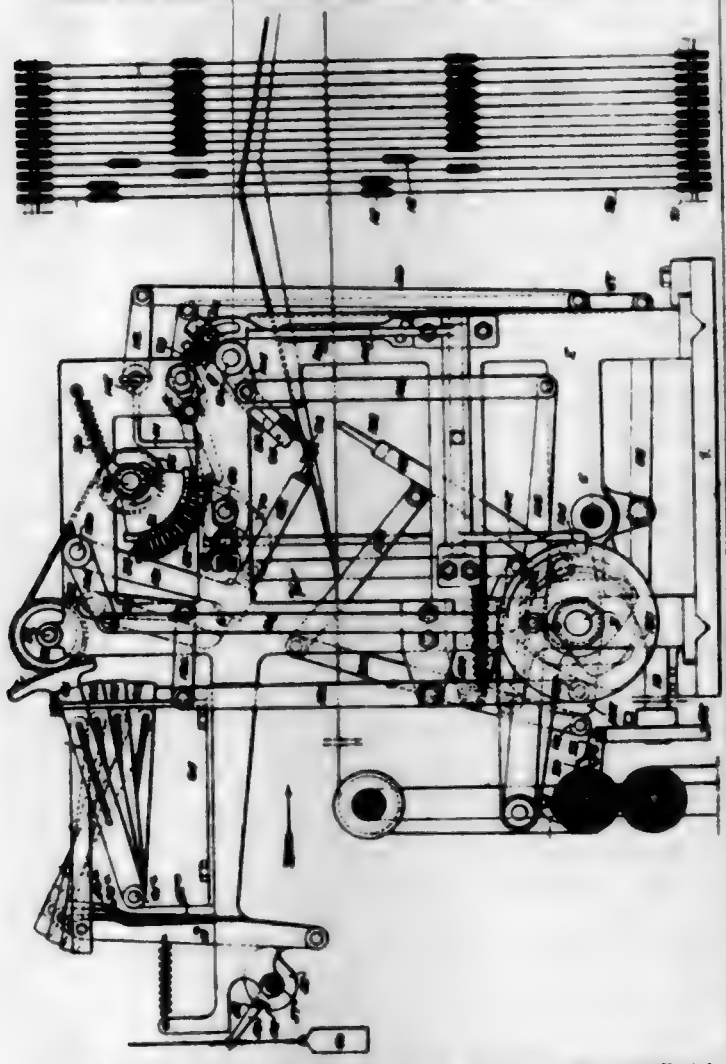
Claim.—1. A spoke-tightener consisting of two interlocking washer-plates, each essentially U-shaped, one of said plates being provided with

angular shoulders at its ends and a boss intermediate its ends, the other plate having an angular boss at its center, the ends being devoid of shoulders, substantially as described.

2. A spoke-tightening device comprising the interlocking washer-plates C and C', the plates C having a central angular boss C^4, the plates C' having the end shoulders C^3 and the central boss C^5, said shoulders and boss extending in the same direction for the purpose described.

706,072. LOOM FOR WEAVING TUFTED PILE FABRICS.

CHARLES H. LANDENBERGER, Philadelphia, Pa. Filed Mar. 2, 1899. Renewed Jan. 10, 1902. Serial No. 89,216. (No model.)



Claim.—1. The combination, in a loom for weaving tufted pile fabrics, of knot-forming mechanism, means for supplying yarn thereto, and provision for lifting pairs of ground warp-threads above the general level of said warp for the reception of the knots, substantially as specified.

2. The combination, in a loom for weaving tufted pile fabrics, of knot-forming mechanism, means for supplying yarn thereto, provision for lifting pairs of ground warp-threads above the general level of the warp for the reception of the knots, and mechanism for intermittently altering the lateral relations of the knot-forming devices and the ground-warp, substantially as specified.

3. The combination, in a loom for weaving tufted pile fabrics, of knot-forming mechanism, means for supplying yarn thereto, and provision for lifting above the general level of the ground-warp, first one and then the other of a pair of warp-threads intended to receive the knot, substantially as specified.

4. The combination, in a loom for weaving tufted pile fabrics, of knot-forming mechanism, means for supplying yarn thereto, provision for lifting pairs of ground warp-threads above the general level of the warp for the reception of the knots, and mechanism for shedding the warp for the introduction of one or more filling-threads after the formation of a row of knots across the warp, substantially as specified.

5. The combination, in a loom for weaving tufted pile fabrics, of knot-forming mechanism, means for supplying yarn thereto, provision for lifting pairs of ground warp-threads above the general level of the warp for the reception of the knots, and a beating-up comb acting upon said knots after they have been engaged with the warp, substantially as specified.

6. The combination, in a loom for weaving tufted pile fabrics, of knot-forming mechanism comprising a pair of looping-nippers and a pair of knotting-nippers, means for supplying yarn to the looping-nippers, provision for lifting above the level of the warp, first one and then the other of a pair of threads intended to receive the knot, mechanism for intermittently altering the lateral relations of the knot-forming mechanism and the ground-warp, means for shedding the warp for the introduction of one or more binding-wefts, after the formation of a row of knots, and beating-up devices, substantially as specified.

7. The combination in yarn-selecting mechanism for looms, of a series of levers, and a series of separators, said parts presenting to each other wedge bearings which increase in angle in geometrical progression throughout the series, the separators being interposed between successive levers of the set and each having a sliding bearing upon each of the levers between which it is interposed, with means for moving the members of one of said series of elements in respect to those of the other series, substantially as specified.

8. The combination in yarn-selecting mechanism for looms, of a movable yarn-controller, a series of levers having slots therein the slots of the different levers being at different angles, separators engaging with slots of adjoining levers, means for operating said separators, and provision for connecting the first lever of the series to the movable yarn-controller, substantially as specified.

9. The combination in yarn-selecting mechanism for looms, of a movable yarn-controller, a series of levers having slots at different angles, a series of bars having pins engaging with the slots of adjoining levers, provision for connecting the first lever of the series to the movable yarn-controller, and mechanism for reciprocating said bars, substantially as specified.

10. The combination in yarn-selecting devices for looms, of a series of levers, and a series of interposed separators presenting to each other bearings which increase in angle in geometrical progression throughout the series, and mechanism for moving the members of one of said series of elements in respect to those of the other, said mechanism having as elements slotted cams, and arms having projections playing in the slots of said cams whereby said arms may have lost motion, substantially as specified.

11. The combination in a loom for weaving tufted pile fabrics, of a yarn-controller, a pair of draft-nippers, looping-nippers comprising two independent nipping devices laterally separated from each other, provision for opening and closing each nipping device, and for moving the draft-nippers from and toward the yarn-controller, a pair of shears, and means for operating said shears so as to sever the yarn drawn from the yarn-controller by the draft-nippers, substantially as specified.

12. The combination in a loom for weaving tufted pile fabrics, of a yarn-controller, a pair of draft-nippers, provision for opening and closing the same and for moving them toward and from the yarn-controller, a pair of shears for severing the yarn drawn out by the draft-nippers, means for operating said shears, a pair of looping-nippers, comprising two independent nipping devices laterally separated from each other and means for opening and closing said nipping devices and for raising and lowering the same whereby the draft-nippers can draw yarn between the open jaws of the looping-nippers when the latter are raised, and said jaws can then be closed upon the yarn and the nippers caused to descend, substantially as specified.

13. The combination in a loom for weaving tufted pile fabrics, of a pair of looping-nippers, consisting of independent nipping devices laterally separated from each other, means for opening and closing the jaws of said nippers, provision for raising and lowering the nippers, and mechanism for causing each of the nipping devices of the nippers to turn as they are raised and lowered whereby they are caused to wrap a loop of pile-yarn around a pair of ground warp-threads, substantially as specified.

14. The combination in a loom for weaving tufted pile fabrics, of a pair of nippers for laying a loop of yarn around a pair of ground-warp threads, said pair of nippers comprising independent nipping devices laterally separated from each other with knotting-nippers and means for operating the same whereby they are caused to pass between the threads of the ground-warp while closed, are then expanded so as to embrace the loop of pile-yarn, are then closed upon said loop, and then raised so as to draw the free ends of the loop between the ground pile-threads, substantially as specified.

15. The combination in a loom for weaving tufted pile fabrics, of a swinging arm carrying a pair of shafts geared together and each having a head with nippers thereon, a rack engaging with a pinion on one of said shafts, and means for swinging said arm and reciprocating the rack, substantially as specified.

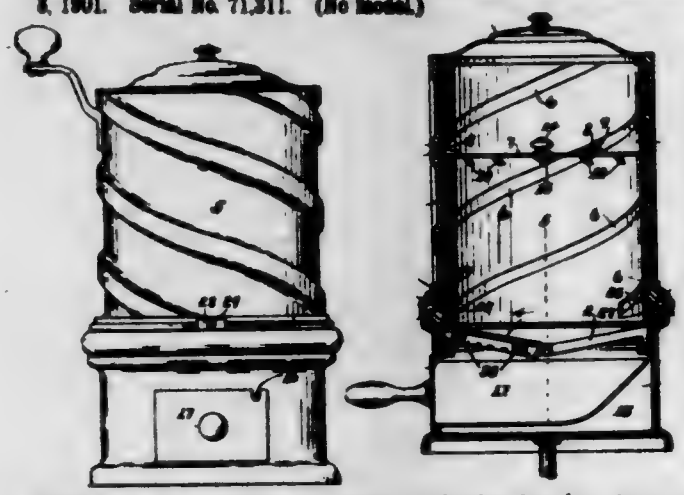
16. The combination in a loom for weaving tufted pile fabrics, of knot-forming devices, a shaft having mechanism for operating said de-

vices, a movable frame on which said knot-forming devices are mounted, a shaft provided with means for imparting movement to said frame, and means for imparting intermittent movement of partial rotation to said shaft on each rotation of the shaft which operates the knot-forming devices, substantially as specified.

17. The combination in a loom for weaving tufted pile fabrics, of knot-forming devices, a shaft having mechanism for operating said devices, take-up mechanism for the finished fabric, a shaft having means for operating said take-up mechanism, and provision for imparting movements of partial rotation to said shaft on each rotation of the shaft which operates the knot-forming devices, substantially as specified.

18. The combination in a loom for weaving tufted pile fabrics, of heddles and take-up mechanism for controlling a ground-warp, a series of sets of knot-forming devices disposed at intervals throughout the lateral extent of said warp, provision for operating said sets of knot-forming devices, and means whereby the lateral relations of the knot-forming devices and the ground-warp are changed by a succession of intermittent movements until a space of ground-warp has been covered equal to the distance between adjoining knot-forming devices of the series, substantially as specified.

706,078. MACHINE FOR CUTTING OR SHAVING ICE. PIERCE H. LIPPINCOTT, Philadelphia, Pa., assignor to American Soda Fountain Company, Jersey City, N. J., a Corporation of New Jersey. Filed Aug. 8, 1901. Serial No. 71,311. (No model.)



Claim.—1. In a machine for cutting or shaving ice, &c., the combination of the cutting-blades, the rotatable receptacle mounted above said blades, and having the screw-threads, together with the follower within said receptacle, having parts adapted to engage said threads, and having also the points or projections on its under side, all constructed and adapted to operate substantially as and for the purpose set forth.

2. In a machine for cutting or shaving ice, &c., the combination of the base, the non-rotatable plate, the cutting-blades secured thereto, the rotatable receptacle mounted on said base and having the screw-threads in its inner periphery, and the follower within said receptacle having parts or projections adapted to engage said threads, and having also the points or projections on its under side substantially as and for the purpose set forth.

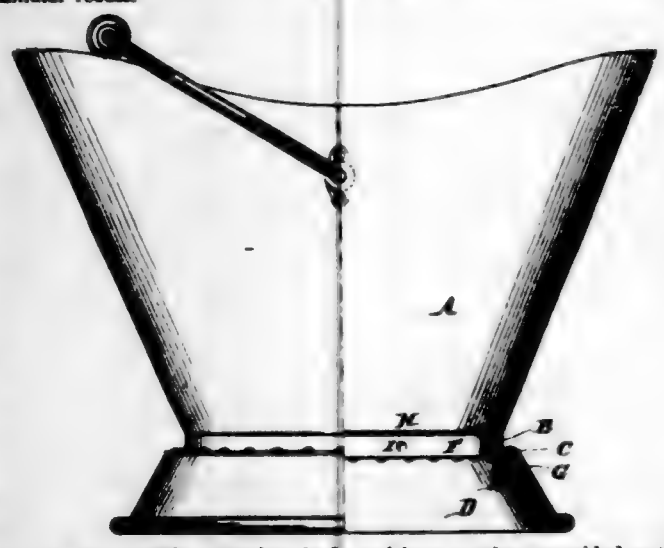
3. In a machine for cutting or shaving ice, &c., the combination of the base, the fixed cutting-blades mounted therein, the rotatable receptacle above said blades, having the screw-thread grooves in its inner periphery, and the follower within said receptacle having the rollers adapted to enter said grooves and having also the points or projections on its under side, substantially as and for the purpose set forth.

4. In a machine for cutting or shaving ice, &c., the combination of the base, the removable non-rotatable plate, the blades secured thereto, the rotatable receptacle supported above said plate upon balls in a raceway between it and receptacle and a flange of said base, the screw-threads in said receptacle, and the follower within the latter having parts adapted to engage said threads and having also the points or projections on its under side, substantially as and for the purpose set forth.

706,074. SCUTTLE, BUCKET, &c. EDWARD M. LOCKWOOD, Jr., Darby, Pa. Filed Nov. 13, 1901. Serial No. 82,078. (No model.)

Claim.—1. A scuttle or bucket having a body and base united so as to form an annular groove or recess opening vertically upward and unobstructed from above, combined with a replaceable bottom having a downwardly-extending annular flange of smaller diameter than the body part detachably clamped in position in the annular groove and located at the bottom of the body portion and adapted to be pressed into or out of the annular groove without separating the body and base portions.

2. In a scuttle or bucket, a body portion and a base portion permanently secured together and provided at their juncture with an annular recess upon the inside opening vertically upward and of less diameter than the smallest diameter of the body portion, in combination with the replaceable bottom fitting into the opening in the bottom of body portion and having its perimeter downwardly flanged and adapted to fit into the annular recess.



3. In a scuttle or bucket, body and base portions provided at their junction with an annular recess of less diameter than the smallest inside of the body portion and opening upward, in combination with a replaceable bottom of smaller diameter than the smallest diameter of the body portion fitted within the body portion and having its perimeter downwardly flanged and extended into the annular recess and held in place by a suitable locking means comprising a hole in one of the parts and a projection on the other snapping into the hole.

4. In a scuttle or bucket the body portion having at its smallest diameter a vertical portion B and having secured to it below said portion B a part E terminating in an internal upward annular flange F forming the deep annular groove or recess L between it and the portion B of the body and of less diameter than the smallest diameter of the body, in combination with the bottom H of less diameter than the smallest diameter of the part B of the body and having a downwardly-extending annular flange K fitted into the annular recess.

5. In a scuttle or bucket, the body portion having at the bottom a base portion permanently riveted to the body portion and having its top provided with an upwardly-extending internal annular flange F forming the deep annular groove or recess L inside of the line of rivets, in combination with the bottom H of less diameter than the smallest diameter of the body portion and having a downwardly-extending annular flange K adapted to fit into the annular recess.

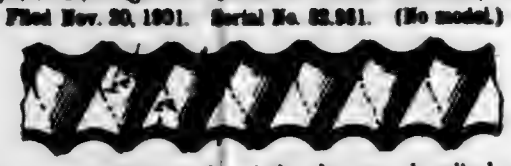
6. In a scuttle or bucket, the body and base portions permanently secured together and having their juncture formed with a vertical annular flange on its interior, in combination with a bottom of less diameter than the diameter of the body portion having a downwardly-extending flange at its perimeter adapted to fit tightly over the annular flange and held in place independently of the means of uniting the body and base portions.

706,075. PROCESS OF CLARIFYING LIQUIDS. HANS LUDERER, Frankfort-on-the-Main, Germany, assignor to Ludwig Wilhelm Gans, Frankfort-on-the-Main, Germany. Filed Jan. 21, 1902. Serial No. 90,702. (No specimens.)

Claim.—1. The process of clarifying solutions by adding thereto a solution of gelatin and an oxidizing agent by which the gelatin is coagulated.

2. The process of clarifying solutions by adding thereto a solution of gelatin and an oxidizing agent by which the gelatin is coagulated while the solution is subjected to heat.

706,076. FLEXIBLE CONDUIT OR TUBE. GEORGE A. LOVE, Brooklyn, N. Y., assignor of one-half to Thomas E. Quinn, New York, N. Y. Filed Nov. 20, 1901. Serial No. 83,081. (No model.)



Claim.—1. A conduit or tube of the character described comprising a spirally-wound strip having grooves or depressions on opposite sides of the central or median line, the groove or depression of one convolution on one side of the strip lapping and interlocking with the groove or depression on the opposite side of the strip of the next convolution, substantially as described.

2. A conduit or tube of the character described comprising a spi-

rally-wound strip having longitudinally-extending grooves or depressions, the groove or depression on one side of the strip lapping and interlocking with the groove or depression on the opposite side of the strip, substantially as described.

3. A conduit or tube of the character described comprising a spirally-wound strip having similarly-disposed grooves or depressions on opposite sides of the central or median line, the groove or depression on one side of the strip lapping and interlocking with a similar groove or depression on the opposite side of the strip, substantially as described.

4. A conduit or tube of the character described comprising a spirally-wound strip having longitudinally-disposed grooves or depressions on opposite sides of the central or median line, said grooves or depressions having their concave surfaces facing outwardly, the convex surface of one side of the strip meshing with the concave surface of the opposite side of the strip, substantially as described.

708,077. ROTARY ENGINE. WILLIAM J. MASON, Chicago, Ill., assignor of one-third to Charles E. Wyman, Chicago, Ill. Filed Sept. 3, 1901. Serial No. 73,126. (No model.)

Claim.—1. In a rotary engine, a rotatable cylinder having pistons, means to operate the pistons, a stationary drum within the cylinder having inlet and exhaust passages, and a radially-slidable abutment seated in the drum and adapted to be forced by steam-pressure into contact with the cylinder.

2. In a rotary engine, a rotatable cylinder, a stationary drum within the cylinder, inlet and exhaust ports, suitable pistons and means to operate the same, and a wedge-shaped radially-slidable abutment loosely seated in a recess in the drum and adapted to be forced by steam-pressure into contact with the cylinder.

3. In a rotary engine, a rotatable cylinder, a stationary drum within the cylinder having a radially-slidable abutment projecting into contact with the cylinder pistons carried by the cylinder and means to operate the same, and inlet and exhaust passages in the drum.

4. In a rotary engine, in combination with a rotatable cylinder having grooves therein to receive pistons, and a stationary drum within the cylinder having inlet and exhaust passages, of a radially-movable abutment on the drum in contact with the cylinder, the contact-face of the abutment being of greater width, circumferentially, than the said grooves.

5. In a rotary engine, a rotatable cylinder, a stationary drum in the same, a radially-movable abutment carried by the drum, radially-slidable pistons carried by the cylinder and adapted to retreat into recesses therein, arms to operate the pistons having rock-shafts extending without the cylinder, levers connected to the shafts and cam mechanism to actuate the levers.

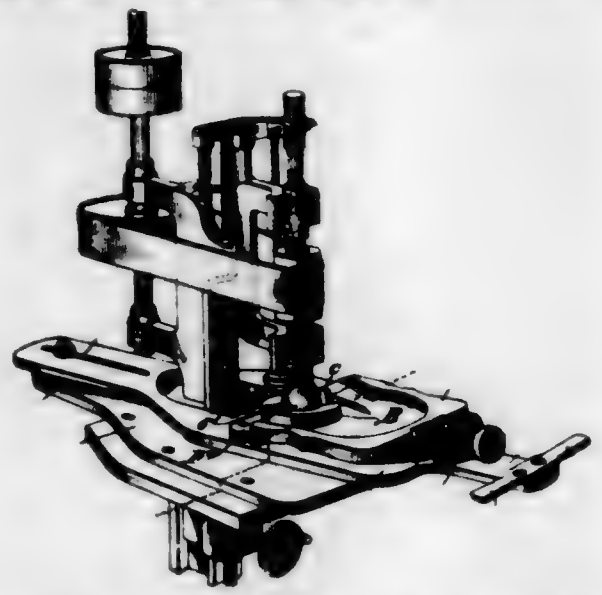
6. In a rotary engine, a rotatable cylinder a stationary drum within the same, a radially-movable abutment carried by the drum, radially-slidable pistons carried by the cylinder and adapted to retreat into recesses therein, arms to operate the pistons having rock-shafts extending without the cylinder, levers connected to the shafts, and bowed arms connected to the levers, said arms having weighted ends diametrically opposite the pistons, a face-plate having a cam-groove and pins running therein connected to the levers.

706,078. CUTTER-HEAD. FRANCIS O. MECHLIN, Washington Court-House, Ohio. Original application filed Aug. 30, 1901, Serial No. 73,841. Divided and this application filed Jan. 10, 1902. (No model.)

Claim.—1. A cutter-head comprising a circular body having a convex face or bottom, and a substantial strengthening boss or hub on its opposite face, and radial slots extending from the periphery of said body to the periphery of said boss and continuing thence to the center in the form of undercut recesses beneath said boss, together with knives fitted in said slots so that their inner ends in effect meet; substantially as described.

2. A cutter-head comprising a circular body having a convex face or bottom, and a substantial strengthening boss or hub on its opposite face, and radial slots extending from the periphery of said body to the periphery of said boss and continuing thence to the center in the form of undercut recesses beneath said boss, together with knives having slotted shanks adjustably secured in said slots and inner portions of reduced width extending inward in said undercut recesses to a point at the center; substantially as described.

706,079. MEANS FOR CUTTING SADDLE-SEAT BOTTOMS FOR CHAIRS. FRANCIS O. MECHLIN, Washington Court-House, Ohio. Filed Aug. 30, 1901. Serial No. 73,841. (No model.)

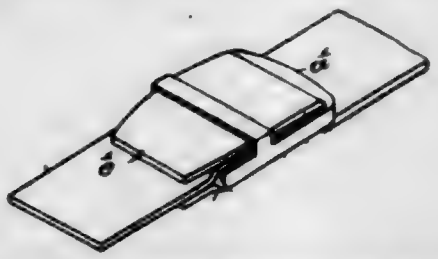


Claim.—1. In combination with the support and guide-plate having substantially the form of a lawn-tennis racket, the superposed sliding table having a reduced longitudinally-slotted portion pivoted to the reduced portion of said guide-plate by a pivot-bolt passing through said slot, and having an approximately lawn-tennis-racket-shaped slot on its under side, a stud on said guide-plate working in said slot for controlling the forward-and-back and sidewise movements of the table, and a clamping device for holding the work in a fixed position in engagement with the cutter-head; substantially as described.

2. A work-supporting sliding table comprising a fixed member and a movable member having rearward extensions pivotally connected together at one side of the machine-standard, the movable member being longitudinally slotted to receive the pivot-bolt, a substantially lawn-tennis-racket-shaped guide slot or groove in the surface of one member and a projection on the confronting surface of the other member working in said slot or groove, together with means on the reverse side of the movable or superposed member for holding the work in a fixed position for the action of the cutter-head; substantially as described.

3. In a machine of the character described, a work-supporting longitudinally-slidable and sidewise-movable table comprising a base-plate having an extension rearward of the machine-standard, a movable plate or table proper having a rearward extension pivotally connected with the extension of said base-plate and longitudinally slotted to receive the pivot-bolt, together with means for limiting and controlling the forward-and-back and sidewise movements of the table, consisting of a slot or groove on one of said plates engaged by a stud or projection on the other, and means carried by the movable member for holding the form or work to be cut in a fixed position thereon; substantially as described.

706,080. BUCKLE. JAMES E. MITCHELL, Lowell, Mass., assignor of three-fourths to George B. Mevis, George F. Stiles, and Charles Fredericks, Lowell, Mass. Filed Mar. 19, 1901. Serial No. 51,821. (No model.)

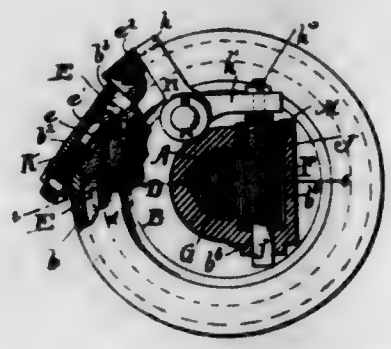


Claim.—1. In a buckle, the main frame, having the bracing cross-bar or keeper at the outside, the guide rods or wires adjacent to the side bars of the frame, the skeleton-form binder-plate engaging said guide-

rods, lying in the plane of the main frame, and having the opening adapted for the insertion of a finger for convenient operation, and the compression-springs between main frame and binder-plate, and surrounding said guide-rods, substantially as specified.

2. In a buckle, the main frame having the bracing cross-bar or keeper at the outside, the guide rods or wires adjacent to the side bars of the frame, the skeleton-form binder-plate engaging said guide-rods, and lying entirely within the plane of the buckle, the compression-springs between main frame and binder-plate, and surrounding said guide-rods, the front bars of binder-plate and buckle-frame being adapted to slide upon one another and the forward edge of the front bar of the binder-plate, and the rear edge of the front bar of the main frame, being thinned for better locking effect, substantially as specified.

706,081. **FRICTION-CLUTCH.** Louis P. Mooers, Cleveland, Ohio, assignor to the Peerless Manufacturing Company, Cleveland, Ohio, a Corporation of Ohio. Filed Oct. 30, 1901. Serial No. 80,426. (No model.)



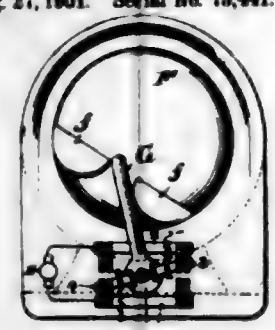
Claim.—1. In a friction-clutch, the combination of two independently-rotatable members mounted upon the same axis and having respectively cylindrical flanges of different diameters, of which the smaller flange lies within the larger flange, a split clamping-ring in the annular space between said flanges and lying normally out of contact with the smaller flange, means preventing relative movement of the outer flange and one end of said ring, an external shoulder on the other end of said ring, a bent lever pivoted to the side of the member of which the larger flange is a part on a pivot parallel with the axis of said member, said lever having one arm which extends outward from its pivot and is bent over the top of the flange and into contact with the external shoulder on the ring, and mechanism engaging with the other end of said lever whereby to rock it, substantially as and for the purpose specified.

2. In a friction-clutch, the combination of two independently-rotatable members mounted upon the same axis having respectively cylindrical flanges of different diameters of which the smaller flange lies within the larger flange, a split clamping-ring in the annular space between said flanges and lying normally out of contact with the smaller flange, means preventing relative movement of the outer flange and one end of the ring, an external shoulder on the other end of said ring, a bent lever pivoted to the member of which the larger flange is a part having one arm which extends outward and over the top of the flange and into contact with the external shoulder on the ring, a nut rotatively mounted in the member carrying the larger flange, means preventing the endwise movement of said nut, a screw upon which the nut is fitted and which is adapted to engage with one arm of said bent lever, means preventing the rotation of said screw but permitting its endwise movement, and mechanism for rotating said nut, substantially as and for the purpose specified.

3. In a friction-clutch, the combination of a hollow shaft, a member B secured thereto, and having a cylindrical flange, a member D rotatively mounted upon said shaft and having a cylindrical flange which projects into the flange of the member B, a split clamping-ring lying in the annular space between said flanges and having one end connected with the member B and having near its other end an external shoulder a bent lever pivoted to the member B having one arm adapted to engage with said shoulder, a nut rotatively mounted in a recess formed partly in the member B and partly in the hollow shaft and intersecting the hole through said shaft, said nut having external gear-teeth, means preventing the endwise movement of said nut, a screw fitted to said nut and having a squared end which enters and is movable in a square hole in the bottom of said recess, the opposite end of said screw being adapted to engage with an arm of said bent lever, and a rack movable through the hollow shaft and engaging with said nut, substantially as and for the purpose specified.

4. In a friction-clutch, the combination of a rotatable member B having a cylindrical flange, an independently-rotatable member D mounted in the same axial line and having a cylindrical flange of smaller diameter which lies within the flange of the member B, a split clamping-ring lying in the annular space between said flanges and having at one end an external groove with a shoulder at its end, a screw screwing through the flange of the member B and lying partly in said groove and abutting against said shoulder on the ring, and mechanism operating upon the other end of the split ring to reduce its diameter, substantially as and for the purpose specified.

706,082. **AUTOMATIC POLE-REVERSER.** Morris Moskowitz, Brooklyn, N. Y., assignor to James H. Young, trustee, New York, N. Y. Filed Aug. 27, 1901. Serial No. 73,441. (No model.)



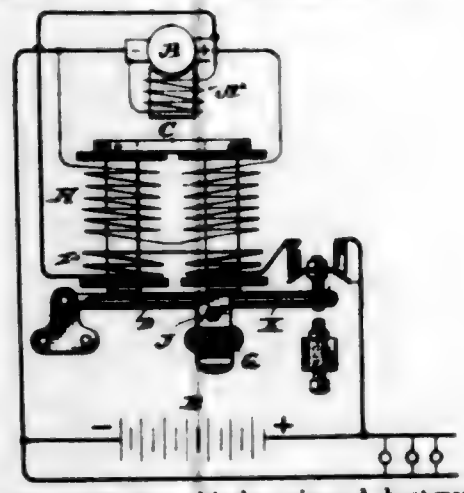
Claim.—1. In combination with an electric generator and its armature, means for automatically reversing the polarity of the generator, consisting of a friction pulley and brake operated by the armature-shaft of said generator, a centrifugal governor connected thereto, and a switch controlled by the movement of said pulley, substantially as set forth.

2. In combination with a shaft subject to reversal of rotation, an automatic pole-changer controlled thereby and combining frictional means for actuating it in a direction corresponding with the direction of rotation of said shaft, and means for reducing the friction when a given speed limit is reached.

3. In combination with a shaft subject to reversal of rotation, an automatic pole-changer controlled thereby and combining frictional means for actuating it in a direction corresponding with the direction of rotation of said shaft, and centrifugal means for reducing the friction as the speed increases.

4. In combination with a shaft subject to reversal of rotation, an automatic pole-changer controlled thereby and combining frictional means for actuating it in a direction corresponding with the direction of rotation of said shaft, having a spring acting to produce the friction and a centrifugal means for counteracting the spring as the speed increases.

706,088. **AUTOMATIC SWITCH.** Morris Moskowitz, Brooklyn, N. Y., assignor to James H. Young, trustee, New York, N. Y. Filed Sept. 28, 1901. Serial No. 76,842. (No model.)



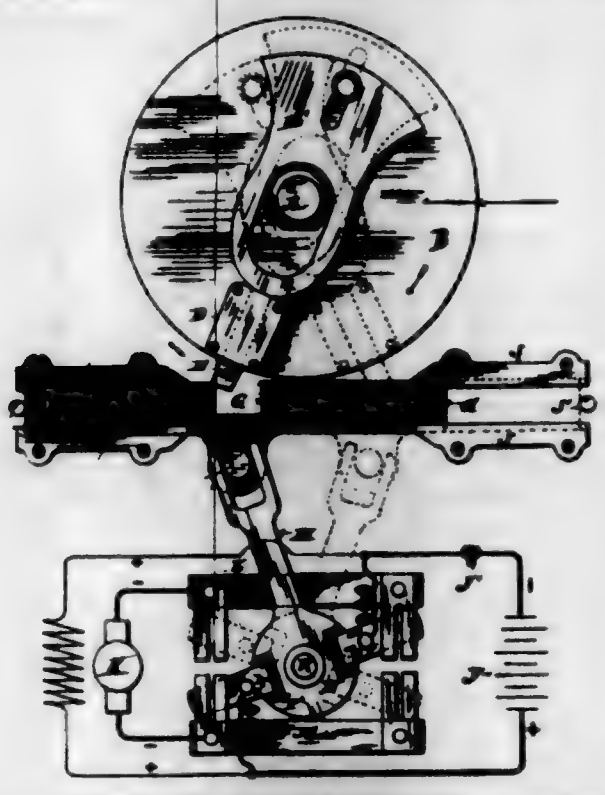
Claim.—The combination with the series and shunt wound electromagnet of a pivoted switch-arm actuated by the said electromagnet and provided with guides for a weight, and a weight fitted to said guides and sliding thereon and having integral with it two clamping-jaws and a clamp-screw by which it may be fixed in position thereon.

706,084. **AUTOMATIC SWITCH.** Morris Moskowitz, Brooklyn, N. Y., assignor to James H. Young, trustee, New York, N. Y. Filed Sept. 28, 1901. Serial No. 76,843. (No model.)

Claim.—1. In combination with an electrical switch and as a means for actuating the switch when the direction of rotation of a rotary part reverses, a rotary mechanism, and connections for positively, in contradistinction to frictionally, engaging and actuating the switch in a direction corresponding to the direction of rotation, and means for retracting the engaging part when a predetermined speed of rotation is exceeded.

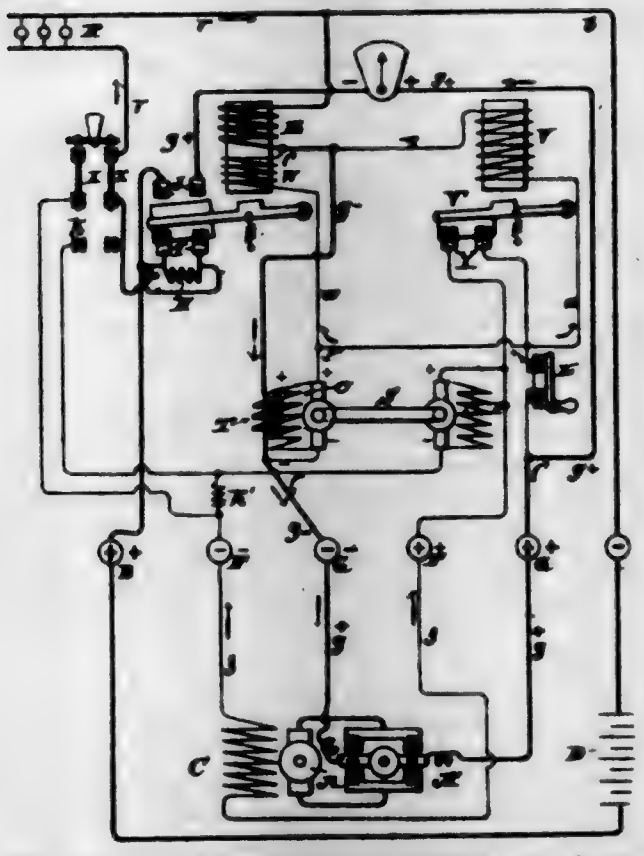
2. In combination with an electrical switch and as a means for actuating the switch when the direction of rotation of a rotary body reverses,

a rotary part suitably mounted and subject to such reversals of rotation, and a retractable engaging device movably mounted upon the said rotary part for engaging and actuating the switch in either direction, the said retractable engaging device being provided with a weight for centrifugally retracting it.



3. In combination with an electrical switch and as a means for actuating the switch when the direction of rotation of a rotary body reverses, a rotary part suitably mounted and subject to such reversals of rotation, a dog provided with a centrifugal retracting device and suitably mounted in guides upon the said rotary part, and a slide-bar connected to actuate the switch and situate in position to be engaged and actuated by the said dog in either direction, substantially as set forth.

706,085. ELECTRICAL SYSTEM FOR LIGHTING AND POWER. Moses Moskowitz, Brooklyn, N. Y., assignor to James H. Young, trustee, New York, N. Y. Filed Sept. 28, 1901. Serial No. 76,844. (No model.)



Claim.—1. As an improvement in an electrical system having a work-circuit, a storage battery with connections for supplying the work-circuit, a generator subject to variations in speed, and connections therefrom for supplying the work-circuit and for charging the battery, the combination therewith of a motor-dynamo connected to derive its motor-current from the generator and having connections for exciting the field-coils of the generator, and having a regulating motor field-coil connected to strengthen the motor-field when the current from the main generator increases.

2. As an improvement in an electrical system having a work-circuit, a storage battery with connections for supplying the work-circuit, a generator subject to variations in speed, and connections therefrom for supplying the work-circuit and for charging the battery, the combination therewith of a motor-dynamo connected to derive its armature-current from the generator and having connections for exciting the field-coils of the generator, and having means for changing its working speed oppositely to the changes of speed of the generator.

3. As an improvement in an electrical system having a work-circuit, a storage battery with connections for supplying the work-circuit, a generator subject to variations in speed, and connections therefrom for supplying the work-circuit and for charging the battery, the combination therewith of a motor-dynamo connected to derive its motor-current from the generator and having connections for exciting the field-coils of the generator, means for regulating the strength of field of the generator, a circuit maker and breaker for the connection from the generator for supplying the work-circuit and battery, and automatic means for closing said circuit-maker when the desired electromotive force of the generator is attained.

4. As an improvement in an electrical system having a work-circuit, a storage battery with connections for supplying the work-circuit, a generator subject to variations in speed, and connections therefrom for supplying the work-circuit and for charging the battery, the combination therewith of a motor-dynamo connected to derive its motor-current from the generator and having connections for exciting the field-coils of the generator, means for regulating the strength of field of the generator, a circuit maker and breaker for the connection from the generator for supplying the work-circuit and battery, and automatic means for closing said circuit-maker when the desired electromotive force of the generator is attained, and means constructed therewith for introducing a compensating resistance into the work-circuit.

5. As an improvement in an electrical system having a work-circuit, a storage battery having connections for supplying the work-circuit, a generator subject to variations in speed, and connections therefrom for supplying the work-circuit and for charging the battery, the combination therewith of self-exciting connections for the generator, automatic means for breaking the last of said connections when a predetermined speed is exceeded, means for separately exciting the generator, and means for regulating such excitation as the speed varies.

6. As an improvement in an electrical system having a work-circuit a storage battery having connections for supplying the work-circuit, a generator subject to variations in speed, and connections therefrom for supplying the work-circuit and for charging the battery, the combination therewith of self-exciting connections for the generator, automatic means for breaking the last said connections when a predetermined speed is exceeded, means for separately exciting the generator, and means for closing the said connections for supplying the work-circuit and charging the battery, when a certain speed has been reached.

7. As an improvement in an electrical system having a work-circuit, a storage battery having connections for supplying the work-circuit, a generator subject to variations in speed, and connections therefrom for supplying the work-circuit and for charging the battery, the combination therewith of self-exciting connections for the generator, automatic means for breaking the last said connections when a predetermined speed is exceeded, a suitably-energized motor-dynamo connected to excite the field of the generator, and means for regulating the excitation as the speed of the generator varies.

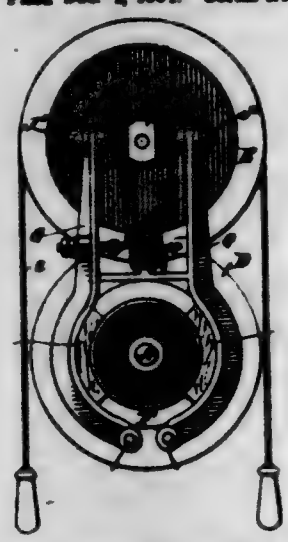
8. As an improvement in an electrical system having a work-circuit, a storage battery having connections for supplying the work-circuit, a generator subject to variations in speed, and connections therefrom for supplying the work-circuit and for charging the battery, the combination therewith of self-exciting connections for the generator, automatic means for breaking the last said connections when a predetermined speed is exceeded, a suitably-energized motor-dynamo connected to excite the field of the generator, and provided with a motor field-coil connected to strengthen the motor-field as the speed of the main generator increases.

9. As an improvement in an electrical system having a work-circuit, a storage battery having connections for supplying the work-circuit, a generator subject to variations in speed, and connections therefrom for supplying the work-circuit and for charging the battery, the combination therewith of self-exciting connections for the generator, automatic means for breaking the last said connections when a predetermined speed is exceeded, a suitably-energized motor-dynamo connected to excite the field of the generator, and provided with means for changing its working speed oppositely to changes in the speed of the generator.

10. As an improvement in an electrical system having a work-circuit,

a storage battery having connections for supplying the work-circuit, a generator subject to variations in speed, and connections therefrom for supplying the work-circuit and for charging the battery, the combination therewith of regulating means for controlling the electromotive force of the generator, a resistance normally included in the generator field-circuit, means for making and breaking the work-circuit, and means for cutting out or short-circuiting the said resistance when the work-circuit is open to increase the electromotive force for charging the battery in excess of that normally required on the work-circuit.

706,086. BRAKE-CONTROLLER. PAUL MILLER, Newark, N. J., assignor to Sprague Electric Company, New York, N. Y., a Corporation of New Jersey. Filed Dec. 4, 1901. Serial No. 84,621. (No model.)



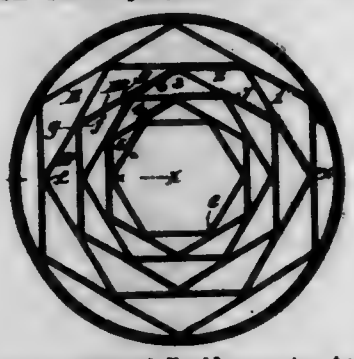
Claim.—1. A brake mechanism comprising a motor-driven shaft, a brake-pulley, spring-actuated brake-arms, adjustable followers carried thereby, a controller-shaft and cam thereon adapted to release said brakes when power is applied and vice versa.

2. A brake mechanism comprising a motor-shaft, a self-acting brake therefor, a controller for said motor, a cam carried by said controller and adjustable means carried by said brake coacting with said cam so that when said motor is started said brake is released and when the power is turned off said brake is applied.

3. A controlling mechanism for rotatable shafts comprising, a motor-driven shaft, a brake-wheel for said shaft, a controller for said shaft, a cam carried by said controller, a brake-arm pivoted at one end and carrying a brake-shoe adapted to coact with said brake-wheel, means for normally holding said brake-shoe in contact with said brake-wheel, and a stop carried by said brake-arm adapted to coact with said cam.

4. A controlling mechanism for a motor-driven shaft comprising a motor-driven shaft, a brake-wheel carried thereby, a controller for said motor-shaft, a cam carried by said controller, brake-arms normally drawn into engagement with said brake-wheel by a spiral spring connecting the two arms together, and means for operating said controller.

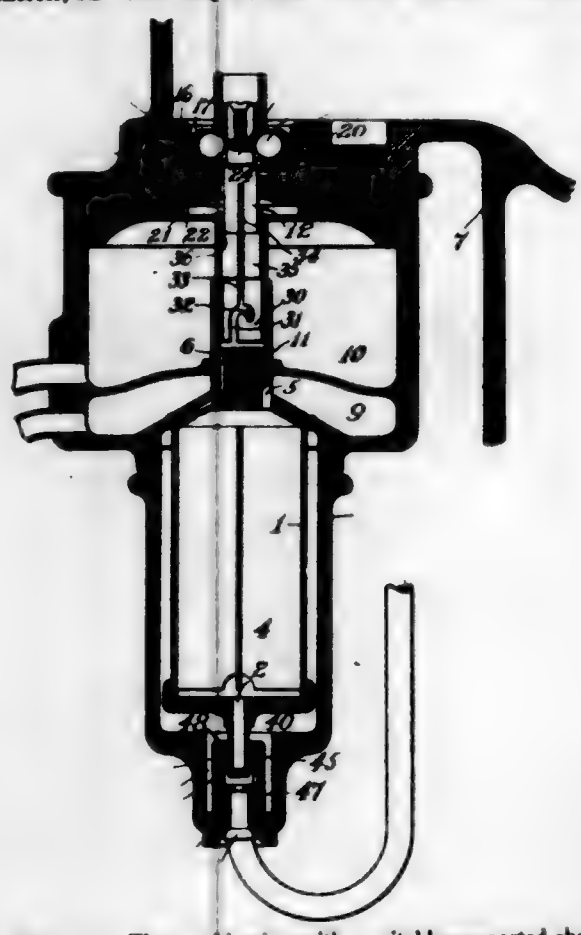
706,087. CENTRIFUGAL SEPARATOR. HERBERT MCCORMACK, Westchester, Pa. Filed July 14, 1900. Serial No. 23,567. (No model.)



Claim.—1. In a centrifugal liquid-separator, two or more vertical walled partitions concentrically arranged therein in contact with each other at intervals to form a circular series of separating compartments between each of the said partitions and the contacting inner or outer one, each of said compartments having skim-milk openings in two of its walls and also cream-openings in two of its walls and said openings providing jointly separate outward and inward flow passages through adjoining inner and outer compartments, substantially as described.

2. In a centrifugal liquid-separator, two or more vertical walled partitions of angular cross-section concentrically arranged in contact with each other at intervals to form a circular series of separating compartments between them, each of said compartments having skim-milk openings in two of its walls and also cream-openings in two of its walls and said openings providing jointly separate outward and inward flow passages through adjoining inner and outer compartments, substantially as described.

706,088. SHAFT-MOUNTING. HERBERT MCCORMACK, Westchester, Pa. Filed July 26, 1901. Serial No. 69,817. (No model.)



Claim.—1. The combination with a suitably-supported shaft of an independently-supported steadying device therefor inclosing the shaft and movable bodily therewith in a lateral direction and means independent of the weight of the device for providing frictional resistance to such movement.

2. The combination with a suitably-supported shaft of a steadying device therefor inclosing the shaft, a seat on which said device is adapted to be moved bodily in a lateral direction by swinging of the shaft, and means for pressing said device against its seat independently of the weight of the device.

3. The combination with a suitably-supported shaft of a steadying device therefor inclosing the shaft, a seat on which said device is adapted to be moved bodily in a lateral direction by swinging of the shaft, and adjustable means for pressing said device against its seat to provide a regulated frictional resistance to such movement independently of the weight of the device.

4. The combination with a suitably-supported rotary shaft of a fixed sleeve loosely inclosing the same and provided with an interior flange, a steadying device loosely located in the annular space between the shaft and the inclosing sleeve, and a spring to press the device against said flange to provide frictional resistance to lateral movement thereof.

5. The combination with a suitably-supported shaft, of a laterally-movable steadying device therefor inclosing the same, a fixed ring or sleeve loosely inclosing the shaft and forming a seat for said steadying device, and a spring or springs for pressing the latter against said seat.

6. The combination with a suitably-supported shaft, of a laterally-movable steadying device therefor inclosing the same, a fixed seat for said movable steadying device, and means for pressing the latter against said seat and for yieldingly pressing the same laterally toward its normal central position.

7. The combination with a shaft, a supporting-bearing therefor and a fixed ring or sleeve loosely surrounding the shaft and forming a bearing-flange, of an independently-supported steadying device comprising a band-ring inclosing the shaft and a conical-seat bearing-ring, and a spring-support for said bearing-ring arranged to press the band-ring against said flange.

8. The combination with a shaft, a supporting-bearing therefor and a fixed sleeve loosely surrounding the shaft and formed with an interior flange, of an independently-supported steadying device comprising a band-ring inclosing the shaft and a conical-seat bearing-ring, and a spring-support for said bearing-ring arranged to press the band-ring against said

flange, said sand-ring and bearing-ring having jointly a limited lateral movement with the shaft.

9. The combination with a shaft and a suspension-bearing therefor, of a non-rebounding laterally-movable frictional steadying device arranged to contact with the dependent portion thereof when the latter is swayed from the normal axis of rotation.

10. The combination with a shaft having a flexible portion, of a suspension-bearing therefor located above said flexible portion, and a laterally-movable frictional steadying device therefor located below the same.

11. The combination with a shaft having a flexible portion, of a suspension-bearing therefor located above said flexible portion and laterally-movable frictional steadying devices located respectively above and below said flexible portion.

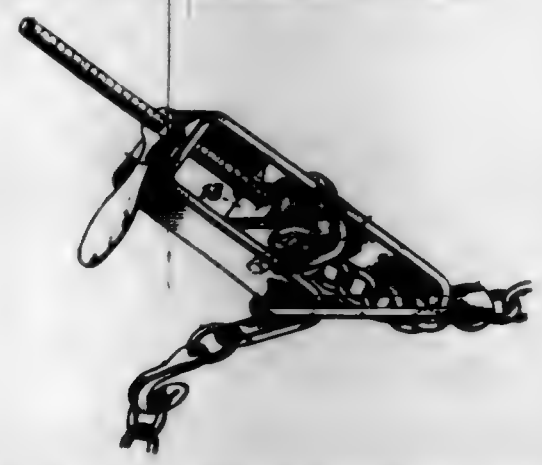
706,089. METHOD OF MANUFACTURING BASIC BESSEMER STEEL. SAMUEL McDONALD, Youngstown, Ohio. Filed Jan. 25, 1902. Serial No. 91,226. (No specimens.)

Claim.—1. In the manufacture of basic Bessemer steel, the method herein described, which consists in pouring successive converter charges into a common receptacle from which the metal is taken to be cast, testing each charge in turn, and varying the duration of each succeeding blow according to the result of the preceding test, substantially as described.

2. In the manufacture of basic Bessemer steel, the method herein described, which consists in blowing a moderate percentage of the total product to be produced in suitable manner for the elimination of phosphorus so far as may be, charging the same into a heat-maintaining receptacle of capacity suitable to hold the entire amount of product desired, taking a test thereof, blowing another moderate percentage of the total product and continuing the after blow for such length of time that when mixed with the charge previously blown, the phosphorous element of the mixture will be at the desired low degree, charging this second moderate percentage into the receptacle and continuing such testing and further blowing, regulating each successive blow by the results of the previous test until the desired quantity is produced, substantially as described.

3. In the manufacture of basic Bessemer steel, the method herein described, which consists in subjecting successive charges to basic Bessemer treatment, testing each charge in turn and varying the duration of the treatment of succeeding charges according to the results of the preceding tests, pouring the charges so treated into a receiving-furnace, and bringing the metal contained in the furnace to a casting temperature, substantially as described.

706,090. LOAD-BINDER. JOSEPH F. HEVILLE, Woodruff, Utah. Filed Mar. 31, 1902. Serial No. 100,577. (No model.)



Claim.—1. A device of the class described comprising a frame composed of two sides and a connecting portion, one of the sides being shorter than the other and provided with means for engaging one end of a flexible connection, means slidable on the other side of the frame for engaging the other end of the flexible connection, and an adjusting device operating between the sides of the frame and connected with the said slidable means, substantially as described.

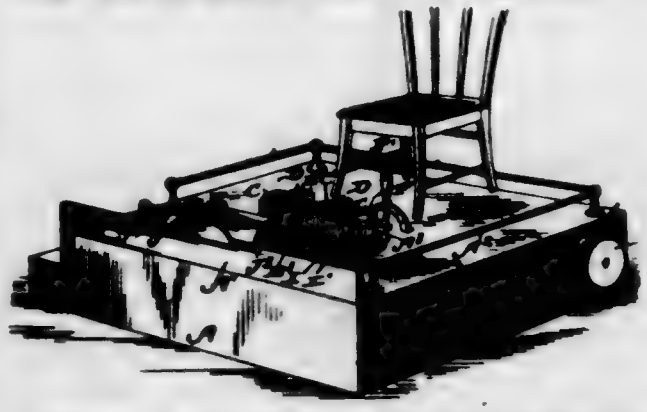
2. A device of the class described, comprising an approximately oblong frame, provided at one side with means for engaging a flexible connection, a slide guided on the other side of the frame and provided with means for engaging the other side of the said connection, and an adjusting device for operating the slide, substantially as described.

3. A device of the class described, comprising an approximately oblong frame provided at one side with means for engaging a flexible connection, a slide arranged within the frame and provided with arms embracing the other side of the same and having a lug at one end and provided at the other end with means for engaging the flexible connection, a screw, connected with the lug and means for adjusting the screw, substantially as described.

4. A device of the class described, comprising an approximately oblong frame, having one side longer than the other, the terminals of the sides being extended in opposite directions, a link connecting the ends of the sides, means connected with the shorter side of the frame for engaging one end of a flexible connection, a slide mounted on the long side of the frame for engaging the other end of the flexible connection, and an adjusting device connected with the slide, substantially as described.

5. A device of the class described, comprising an approximately oblong frame, having one side longer than the other, the terminals of the sides being extended in opposite directions and the end of the long side being provided with a concave inner face, a hook connected with the short side for engaging one end of a chain, a slide mounted on the long side of the frame and having a bifurcated claw for engaging the other end of the chain, a link connecting the end to the sides and an adjusting device for operating the slide, substantially as described.

706,091. SHOE-BLACKING MACHINE. JOHN NICOLET, Canton, Ohio. Filed Mar. 28, 1902. Serial No. 100,575. (No model.)



Claim.—1. In a shoe-polishing machine the combination of a stand, a bracket slidably mounted thereon, a foot-rest pivotally held to the bracket, reciprocating blocks positioned upon the frame and having brushes removably connected thereto, one of the said brushes being movable to and from the said foot-rest, a revolving brush mounted upon the stand in advance of the said foot-rest, and means for operating the said brushes, substantially as set forth.

2. In a shoe-polishing machine, the combination with the stand, having slots arranged in the upper surface thereof, brackets secured to the stand below the said slots, brush-carrying blocks slidably retained upon the said brackets, a crank-shaft mounted within the stand, pitmen connecting the said cranks of the shaft with the said blocks, a brush-carrying shaft revolubly mounted upon the upper portion of the forward end of the stand, a foot-rest slidably held between the said sliding brushes, and means for adjusting one of the said sliding brushes to or from the foot-rest, and means for operating the said brushes, substantially as shown and described.

3. In a shoe-polishing machine, the combination of a stand having slots formed in the upper surface thereof, brackets positioned upon the under side of the said upper surface and below the said slots, blocks slidably retained upon the said brackets, brush-carrying arms mounted upon the said blocks, brushes held upon the arms, one of said arms having a slot formed therein, a crank-shaft projecting through the said slot and having one end terminating in a handle-lever, the said shaft being mounted upon the stand at the ends of one of the said slots, a shaft mounted upon the stand and at the forward end thereof, a brush positioned upon the shaft, and means for operating the said sliding brushes, and means for operating the said revolving brush, substantially as shown and described.

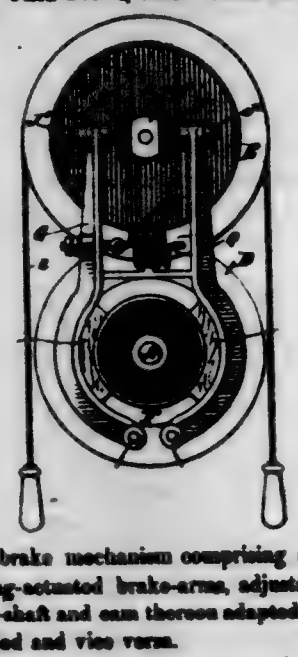
4. In a shoe-polishing machine, the combination of a stand, having slots formed in the upper surface thereof and brackets held upon the under side of the stand and directly below the said slots, blocks slidably held upon the brackets, brush-carrying arms positioned upon the said blocks and having brushes arranged at their upper ends, guide-strips arranged upon the platform upon either side of the slots, a bracket slidably retained in the said strips, a foot-rest pivotally mounted upon the bracket, a shaft carrying a brush mounted upon the platform in advance of the said foot-rest, and means for operating said brushes, substantially as shown and described.

5. In a shoe-polishing machine, the combination of a stand having an adjustable foot-rest mounted thereon, brushes slidably positioned upon either side of the foot-rest, one of which is movable to and from the said foot-rest, a brush revolubly mounted upon the stand at the forward end of the foot-rest, means for operating the said brushes, and means for operating said movable brush to or from the said foot-rest, substantially as shown and described.

6. In a shoe-polishing machine, the combination of a frame, reciprocating blocks arranged thereon, brushes carried by the blocks, one of which is movable laterally, a bracket slidably arranged upon the stand be-

a storage battery having connections for supplying the work-circuit, a generator subject to variations in speed, and connections therefrom for supplying the work-circuit and for charging the battery, the combination therewith of regulating means for controlling the electromotive force of the generator, a resistance normally included in the generator field-circuit, means for making and breaking the work-circuit, and means for cutting out or short-circuiting the said resistance when the work-circuit is open to increase the electromotive force for charging the battery in excess of that normally required on the work-circuit.

706,086. BRAKE-CONTROLLER. PAUL MULLER, Newark, N. J., assignor to Sprague Electric Company, New York, N. Y., a Corporation of New Jersey. Filed Dec. 4, 1901. Serial No. 84,631. (No model.)



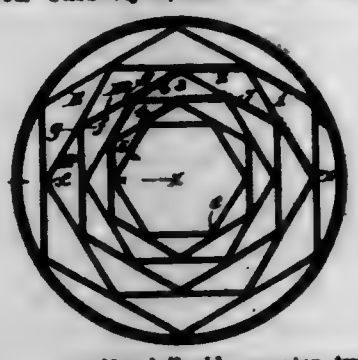
Claim.—1. A brake mechanism comprising a motor-driven shaft, a brake-pulley, spring-actuated brake-arms, adjustable followers carried thereby, a controller-shaft and cam thereon adapted to release said brakes when power is applied and vice versa.

2. A brake mechanism comprising a motor-shaft, a self-acting brake therefor, a controller for said motor, a cam carried by said controller and adjustable means carried by said brake coacting with said cam so that when said motor is started said brake is released and when the power is turned off said brake is applied.

3. A controlling mechanism for rotatable shafts comprising, a motor-driven shaft, a brake-wheel for said shaft, a controller for said shaft, a cam carried by said controller, a brake-arm pivoted at one end and carrying a brake-shoe adapted to coact with said brake-wheel, means for normally holding said brake-shoe in contact with said brake-wheel, and a stop carried by said brake-arm adapted to coact with said cam.

4. A controlling mechanism for a motor-driven shaft comprising a motor-driven shaft, a brake-wheel carried thereby, a controller for said motor-shaft, a cam carried by said controller, brake-arms normally drawn into engagement with said brake-wheel by a spiral spring connecting the two arms together, and means for operating said controller.

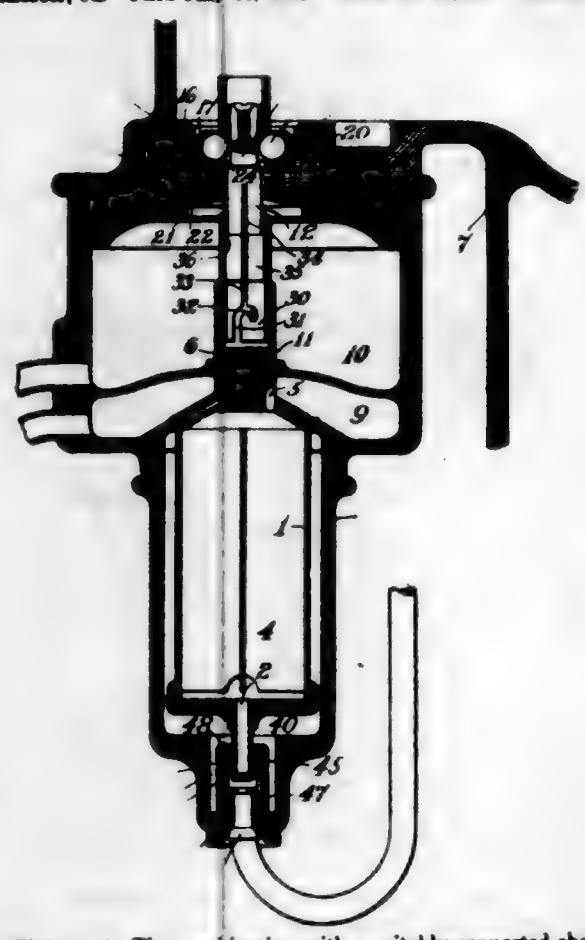
706,087. CENTRIFUGAL SEPARATOR. HERBERT MCCORMACK, Westchester, Pa. Filed July 14, 1900. Serial No. 23,587. (No model.)



Claim.—1. In a centrifugal liquid-separator, two or more vertical walled partitions concentrically arranged therein in contact with each other at intervals to form a circular series of separating compartments between each of the said partitions and the contacting inner or outer one, each of said compartments having skim-milk openings in two of its walls and also cream-openings in two of its walls and said openings providing jointly separate outward and inward flow passages through adjoining inner and outer compartments, substantially as described.

2. In a centrifugal liquid-separator, two or more vertical walled partitions of angular cross-section concentrically arranged in contact with each other at intervals to form a circular series of separating compartments between them, each of said compartments having skim-milk openings in two of its walls and also cream-openings in two of its walls and said openings providing jointly separate outward and inward flow passages through adjoining inner and outer compartments, substantially as described.

706,088. SHAFT-MOUNTING. HERBERT MCCORMACK, Westchester, Pa. Filed July 26, 1901. Serial No. 69,817. (No model.)



Claim.—1. The combination with a suitably-supported shaft of an independently-supported steadying device therefor inclosing the shaft and movable bodily therewith in a lateral direction and means independent of the weight of the device for providing frictional resistance to such movement.

2. The combination with a suitably-supported shaft of a steadying device therefor inclosing the shaft, a seat on which said device is adapted to be moved bodily in a lateral direction by swinging of the shaft, and means for pressing said device against its seat independently of the weight of the device.

3. The combination with a suitably-supported shaft of a steadying device therefor inclosing the shaft, a seat on which said device is adapted to be moved bodily in a lateral direction by swinging of the shaft, and adjustable means for pressing said device against its seat to provide a regulated frictional resistance to such movement independently of the weight of the device.

4. The combination with a suitably-supported rotary shaft of a fixed sleeve loosely inclosing the same and provided with an interior flange, a steadying device loosely located in the annular space between the shaft and the inclosing sleeve, and a spring to press the device against said flange to provide frictional resistance to lateral movement thereof.

5. The combination with a suitably-supported shaft, of a laterally-movable steadying device therefor inclosing the same, a fixed ring or sleeve loosely inclosing the shaft and forming a seat for said steadying device, and a spring or springs for pressing the latter against said seat.

6. The combination with a suitably-supported shaft, of a laterally-movable steadying device therefor inclosing the same, a fixed seat for said movable steadying device, and means for pressing the latter against said seat and for yieldingly pressing the same laterally toward its normal central position.

7. The combination with a shaft, a supporting-bearing therefor and a fixed ring or sleeve loosely surrounding the shaft and forming a bearing-flange, of an independently-supported steadying device comprising a band-ring inclosing the shaft and a conical-seat bearing-ring, and a spring-support for said bearing-ring arranged to press the band-ring against said flange.

8. The combination with a shaft, a supporting-bearing therefor and a fixed sleeve loosely surrounding the shaft and formed with an interior flange, of an independently-supported steadying device comprising a band-ring inclosing the shaft and a conical-seat bearing-ring, and a spring-support for said bearing-ring arranged to press the band-ring against said

flange, said sand-ring and bearing-ring having jointly a limited lateral movement with the shaft.

9. The combination with a shaft and a suspension-bearing therefor, of a non-rebounding laterally-movable frictional steadying device arranged to contact with the dependent portion thereof when the latter is swayed from the normal axis of rotation.

10. The combination with a shaft having a flexible portion, of a suspension-bearing therefor located above said flexible portion, and a laterally-movable frictional steadying device therefor located below the same.

11. The combination with a shaft having a flexible portion, of a suspension-bearing therefor located above said flexible portion and laterally-movable frictional steadying devices located respectively above and below said flexible portion.

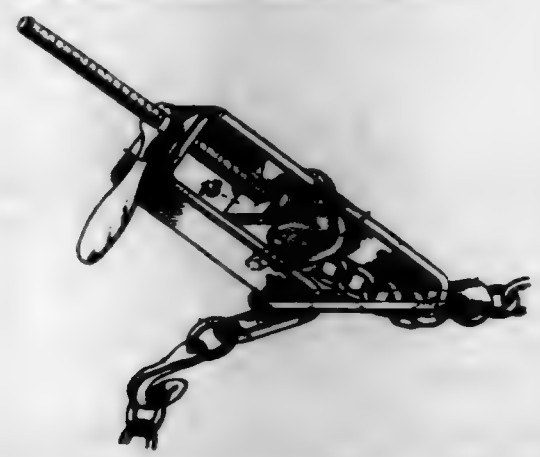
706,089. METHOD OF MANUFACTURING BASIC BESSEMER STEEL. SAMUEL McDOUALS, Youngstown, Ohio. Filed Jan. 28, 1902. Serial No. 91,625. (No specimens.)

Claim.—1. In the manufacture of basic Bessemer steel, the method herein described, which consists in pouring successive converter charges into a common receptacle from which the metal is taken to be cast, testing each charge in turn, and varying the duration of each succeeding blow according to the result of the preceding test, substantially as described.

2. In the manufacture of basic Bessemer steel, the method herein described, which consists in blowing a moderate percentage of the total product to be produced in suitable manner for the elimination of phosphorus so far as may be, charging the same into a heat-maintaining receptacle of capacity suitable to hold the entire amount of product desired, taking a test thereof, blowing another moderate percentage of the total product and continuing the after blow for such length of time that when mixed with the charge previously blown, the phosphorous element of the mixture will be at the desired low degree, charging this second moderate percentage into the receptacle and continuing such testing and further blowing, regulating each successive blow by the results of the previous test until the desired quantity is produced, substantially as described.

3. In the manufacture of basic Bessemer steel, the method herein described, which consists in subjecting successive charges to basic Bessemer treatment, testing each charge in turn and varying the duration of the treatment of succeeding charges according to the results of the preceding tests, pouring the charges so treated into a receiving-furnace, and bringing the metal contained in the furnace to a casting temperature, substantially as described.

706,090. LOAD-BINDER. JOSEPH F. ENVILLE, Woodruff, Utah. Filed Mar. 31, 1902. Serial No. 100,877. (No model.)



Claim.—1. A device of the class described comprising a frame composed of two sides and a connecting portion, one of the sides being shorter than the other and provided with means for engaging one end of a flexible connection, means slidable on the other side of the frame for engaging the other end of the flexible connection, and an adjusting device operating between the sides of the frame and connected with the said slidable means, substantially as described.

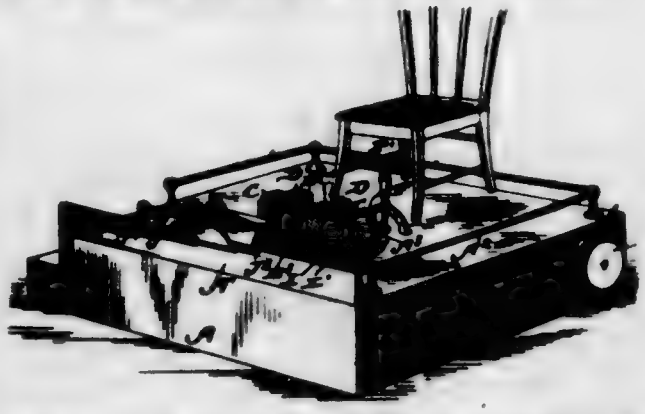
2. A device of the class described, comprising an approximately oblong frame, provided at one side with means for engaging a flexible connection, a slide guided on the other side of the frame and provided with means for engaging the other side of the said connection, and an adjusting device for operating the slide, substantially as described.

3. A device of the class described, comprising an approximately oblong frame provided at one side with means for engaging a flexible connection, a slide arranged within the frame and provided with arms embracing the other side of the same and having a lug at one end and provided at the other end with means for engaging the flexible connection, a screw, connected with the lug and means for adjusting the screw, substantially as described.

4. A device of the class described, comprising an approximately oblong frame, having one side longer than the other, the terminals of the sides, being extended in opposite directions, a link connecting the ends of the sides, means connected with the shorter side of the frame for engaging one end of a flexible connection, a slide mounted on the long side of the frame for engaging the other end of the flexible connection, and an adjusting device connected with the slide, substantially as described.

5. A device of the class described, comprising an approximately oblong frame, having one side longer than the other, the terminals of the sides being extended in opposite directions and the end of the long side being provided with a concave inner face, a hook connected with the short side for engaging one end of a chain, a slide mounted on the long side of the frame and having a bifurcated claw for engaging the other end of the chain, a link connecting the end to the sides and an adjusting device for operating the slide, substantially as described.

706,091. SHOE-BLACKING MACHINE. JOHN NICOLET, Canton, Ohio. Filed Mar. 29, 1902. Serial No. 100,575. (No model.)



Claim.—1. In a shoe-polishing machine the combination of a stand, a bracket slidably mounted thereon, a foot-rest pivotally held to the bracket, reciprocating blocks positioned upon the frame and having brushes removably connected thereto, one of the said brushes being movable to and from the said foot-rest, a revolving brush mounted upon the stand in advance of the said foot-rest, and means for operating the said brushes, substantially as set forth.

2. In a shoe-polishing machine, the combination with the stand, having slots arranged in the upper surface thereof, brackets secured to the stand below the said slots, brush-carrying blocks slidably retained upon the said brackets, a crank-shaft mounted within the stand, pitmen connecting the said cranks of the shaft with the said blocks, a brush-carrying shaft revolubly mounted upon the upper portion of the forward end of the stand, a foot-rest slidably held between the said sliding brushes, and means for adjusting one of the said sliding brushes to or from the foot-rest, and means for operating the said brushes, substantially as shown and described.

3. In a shoe-polishing machine, the combination of a stand having slots formed in the upper surface thereof, brackets positioned upon the under side of the said upper surface and below the said slots, blocks slidably retained upon the said brackets, brush-carrying arms mounted upon the said blocks, brushes held upon the arms, one of said arms having a slot formed therein, a crank-shaft projecting through the said slot and having one end terminating in a handle-lever, the said shaft being mounted upon the stand at the ends of one of the said slots, a shaft mounted upon the stand and at the forward end thereof, a brush positioned upon the shaft, and means for operating the said sliding brushes, and means for operating the said revolving brush, substantially as shown and described.

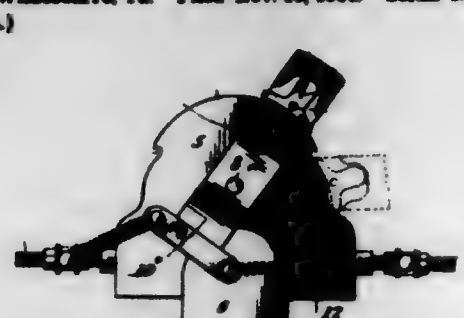
4. In a shoe-polishing machine, the combination of a stand, having slots formed in the upper surface thereof and brackets held upon the under side of the stand and directly below the said slots, blocks slidably held upon the brackets, brush-carrying arms positioned upon the said blocks and having brushes arranged at their upper ends, guide-strips arranged upon the platform upon either side of the slots, a bracket slidably retained in the said strips, a foot-rest pivotally mounted upon the bracket, a shaft carrying a brush mounted upon the platform in advance of the said foot-rest, and means for operating said brushes, substantially as shown and described.

5. In a shoe-polishing machine, the combination of a stand having an adjustable foot-rest mounted thereon, brushes slidably positioned upon either side of the foot-rest, one of which is movable to and from the said foot-rest, a brush revolubly mounted upon the stand at the forward end of the foot-rest, means for operating the said brushes, and means for operating said movable brush to or from the said foot-rest, substantially as shown and described.

6. In a shoe-polishing machine, the combination of a frame, reciprocating blocks arranged thereon, brushes carried by the blocks, one of which is movable laterally, a bracket slidably arranged upon the stand be-

tween the said brushes, a foot-rest pivotally connected to the bracket, a shaft mounted upon the frame in advance of the said brushes and foot-rest, and having a brush mounted thereon, a guard arranged over the revolving brush, and means for operating the brushes substantially as shown and described.

706,092. TROLLEY-POLE CATCH. JAMES A. HORTON, Wilkesbarre, Pa., assignor of one-half to Michael C. Malley and James F. Munday, Wilkesbarre, Pa. Filed Nov. 19, 1901. Serial No. 82,820. (No model.)



Claim.—1. The combination with a pivoted vertically-swinging trolley-pole, of means operated by the downward movement of the pole for automatically locking the pole in its depressed position when the pole is thrown downward, said locking means being normally inoperative during the ordinary movements of the pole throughout the range of movement of the pole.

2. The combination with a vertically-swinging trolley-pole of a relatively movable pawl and catch arranged to hold said pole in its depressed position, means for normally holding said pawl out of engagement with the catch throughout the range of movement of the pole, and means operated by the downward movement of the pole for deflecting said pawl into a direction to engage the catch.

3. The combination with a pivoted vertically-swinging trolley-pole of a catch fixed relatively to the pole, a pawl carried by the pole, means for normally holding said pawl in a direction to pass by the catch, and means for automatically deflecting the pawl in a direction to engage the catch when the trolley-pole is depressed.

4. The combination with a pivoted vertically-swinging trolley-pole of a catch fixed relatively to the pole, a gravity-pawl carried by the pole and arranged to normally swing in a direction away from the catch, and means for automatically deflecting the pawl into a direction to engage the catch when the trolley-pole is depressed.

5. The combination with a pivoted vertically-swinging trolley-pole, of a catch at each side of said pole, and a pawl carried by the pole and having two oppositely-projecting arms, means for normally holding the arm which is uppermost out of engagement with the catch during the normal movement of the trolley-pole, and means for deflecting said uppermost arm in a direction to engage the catch when the trolley-pole is thrown downwardly.

6. The combination with a pivoted vertically-swinging trolley-pole, of a catch at each side of said pole, and a pawl pivotally carried by said pole, said pawl having two arms projecting in opposite directions from its pivotal point, and a central weighted portion adapted to swing the arm which is uppermost away from the adjacent catch.

7. The combination with a standard comprising a plate having a catch at one of its lateral edges and a deflecting-surface below said catch, of a vertically-swinging trolley-pole pivotally mounted upon the standard, and a pawl pivoted to the pole and normally extending in a direction to pass by the catch without engaging, said deflecting-surface being arranged to deflect the pawl into a position to engage the catch.

8. The combination with a standard comprising a plate having a catch at one of its lateral edges, of a trolley-pole pivotally mounted upon the standard, a pawl pivoted to the pole and normally extending in a direction to pass by the catch without engaging, and a deflecting-surface arranged to tilt the pawl into the direction to engage the catch when the pole is depressed.

9. The combination with a standard comprising a plate having a catch at each lateral edge, of a trolley-pole pivotally mounted upon the standard, a pawl pivoted to the pole and having two oppositely-projecting arms, means for holding the arm which is uppermost out of engagement with the adjacent catch, and a deflecting-surface below each catch arranged to tilt said uppermost arm into the direction to engage the adjacent catch.

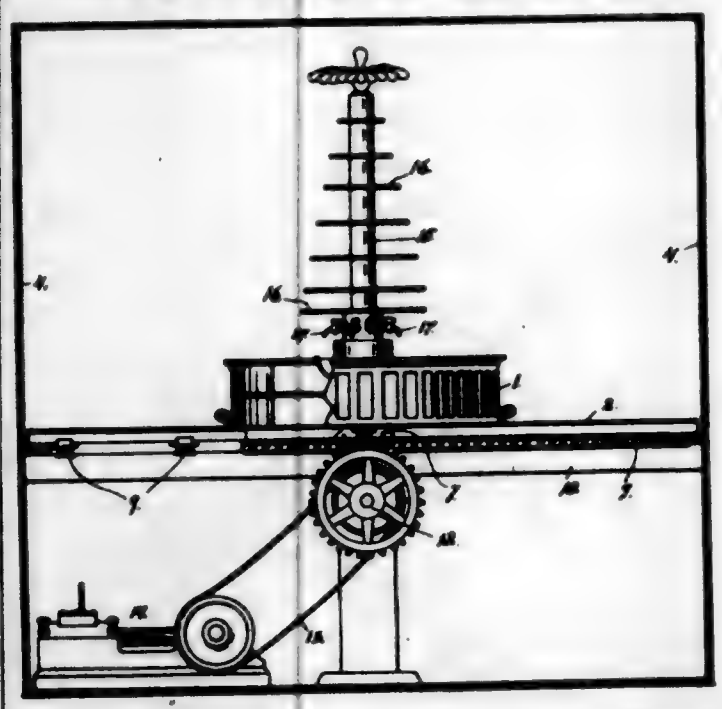
10. The combination with a standard comprising a plate having a catch at each lateral edge, and deflecting-surfaces upon said edges below the catches, of a trolley-pole pivotally mounted upon the standard, a pawl pivoted to the pole and having two oppositely-projecting arms, and means for holding the arm which is uppermost out of engagement with the adjacent catch, said deflecting-surfaces being arranged to be engaged by the pawl and deflected thereby into the proper direction to engage the adjacent catch.

11. The combination with a standard comprising a plate having an upper curved surface, catches at each lateral edge and deflecting-surface below said catches, of a forked trolley-pole pivoted to said plate, and a gravity-pawl pivoted between the arms of the fork, said pawl being arranged to engage the deflecting-surfaces when the trolley-pole is depressed.

706,093. SHADE-HOLDER. THOMAS B. HOWLIN, Sexton, Pa. Filed Apr. 25, 1902. Serial No. 714,390. (No model.)

Claim.—As a new article of manufacture, a window-shade fixture comprising a plate having a perforated attaching-ear projecting centrally from its upper edge, and at its upper edge on each side of said attaching portion bent forwardly and downwardly, and at its lower edge bent forwardly and upwardly, thus forming two flanges upon the front face of the plate having grooves formed therein, the portion of the plate projecting beyond the ends of said flanges being bent forward at right angles thereto so as to close the outer end thereof and formed with a slot extending downwardly from its upper edge, and an arm secured to the bent end portion of the plate and extending upwardly and forwardly and formed at its upper end with a curved seat and twisted adjacent to said seat so that the latter is formed of the flat portion of the arm, substantially as described.

706,094. REVOLVING BAR OR COUNTER. PATRICK J. O'BRIEN, Buffalo, N. Y. Filed June 3, 1901. Serial No. 62,835. (No model.)

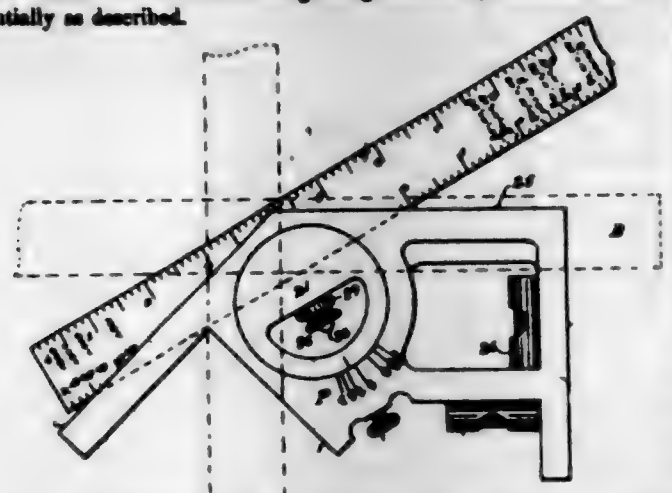


Claim.—An endless bar or counter with attached surrounding section of flooring having a toothed rack and radially-directed arms disposed upon its under surface, said arms carrying roller-bearings, a fixed flooring disposed beneath the aforesaid flooring and having trackways disposed upon its upper surface and over which said roller-bearings are adapted to travel, another section of flooring surrounding the first-mentioned flooring, means for rotating the bar or counter about a common center with its attached surrounding section of flooring, and an open space formed between the inner faces of the bar or counter and said common center.

706,095. COMBINATION SQUARE AND PROTRACTOR. EMANUEL OBERLE, Omaha, Nebr. Filed Oct. 21, 1901. Serial No. 79,458. (No model.)

Claim.—1. A square, comprising a head having a countersunk recess formed therein, a flanged disk finding a bearing in said recess, said disk having a groove in its periphery, a shoe loosely resting in said groove, a set-screw carried by the head and bearing upon the said shoe whereby the disk may be held in its bearing and may be clamped at any

point in its revolution, and a straight-edge carried by the said disk, substantially as described.

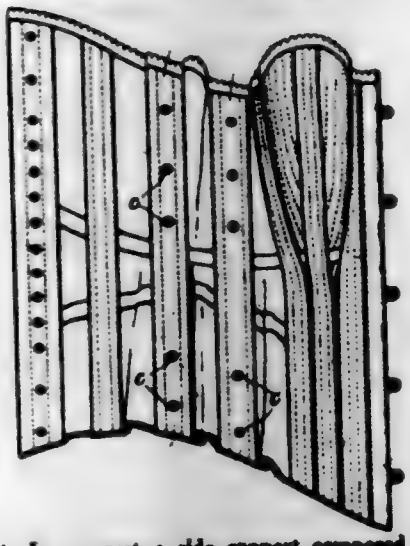


2. A combination-square comprising a head portion a disk having a flange on one side engaging a counterbank bearing in the said head, separate levels arranged at right angles to each other, upon the said head, a straight-edge carried by the said disk, and means traveling in a groove on the periphery of the disk for holding the same in position in connection with the flange of said disk, said means also clamping the disk in its adjusted positions, substantially as described.

3. A combination-tool comprising a head formed with a circular opening, a disk having a groove in its periphery, said disk lying in the opening in said head, a lip or shoulder on said disk engaging one face of said head for preventing lateral movement of said disk in one direction, means carried by said head engaging said peripheral groove for preventing lateral movement of said disk in an opposite direction, and ruling means carried by said disk, substantially as described.

4. A combination-tool comprising a head formed with a circular opening, a disk having an annular groove, said disk lying in the opening in said head, an annular shoulder engaging one face of said head, a set-screw passed through a portion of said head and into said annular groove, and ruling means carried by said disk, substantially as described.

706,096. CORSET. CHARLOTTE A. O'LOAN, Detroit, Mich. Filed Oct. 17, 1901. Serial No. 78,994. (No model.)



Claim.—1. In a corset, a side support composed of one or more corset-steels lying within a vertical pocket or pockets in the side of the corset, and eyelets passing through said pocket or pockets and through the steel or steels therein and turned down upon the fabric of the pockets only, the steel or steels being provided with perforations larger than the eyelets and said eyelets wholly contained within said perforations.

2. As a new article of manufacture, a corset-steel inclosed within a pocket and secured therein against displacement by means of eyelets passing through the fabric of the pocket and through perforations in the steel, said perforations being larger than the eyelets and the eyelets being turned down upon the fabric only and wholly within the perforations in the steel.

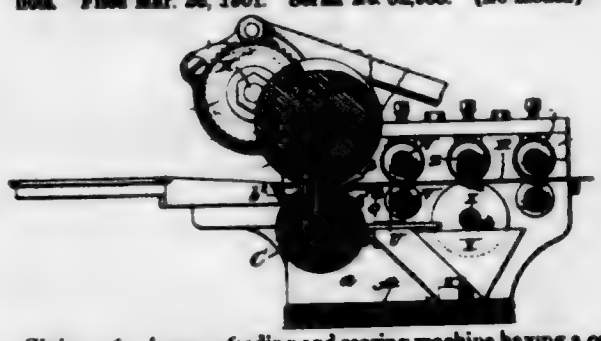
706,097. HEATING-STOVE. ELIAS R. CURT, Jackson, Ohio. Filed Mar. 6, 1902. Serial No. 96,961. (No model.)

Claim.—1. In a stove, the combination with a combustion-chamber and an ash-pit below the same, of an inverted cone communicating with the upper end of the combustion-chamber, a casing inclosing the cone and perforated around said cone, a smoke-pipe projecting through the top of the casing and an inverted cone connected with and spaced from the pipe and adapted to deflect the smoke and gases against the first-mentioned cone before they enter the pipe.

2. In a stove, the combination with a combustion-chamber and an ash-pit below the same, of a heating-drum on top of the combustion-chamber comprising two inverted cones one within the other and forming a smoke-passage between them, a casing inclosing the cones and perforated around the outer cone and a smoke-pipe communicating with the top of the casing and adapted to carry off the waste products of combustion.

3. In a stove, the combination with a combustion-chamber and an ash-pit below the same, of a heating-drum on top of the combustion-chamber, comprising two inverted cones one within the other and forming a smoke-passage between them, a casing inclosing the cones and perforated around the outer cone, a smoke-pipe communicating with the casing and projecting down into the inner cone, a flue connecting the smoke-pipe and ash-pit, and a damper in said smoke-pipe above its connection with the flue.

706,098. PAPER-BLANK FEEDING AND SCORING MACHINE. CHARLES H. PALMER and JOHN W. DENHEAD, Akron, Ohio, assignors to the Diamond Match Company, New York, N. Y., a Corporation of Illinois. Filed Mar. 26, 1901. Serial No. 52,955. (No model.)



Claim.—1. A paper feeding and scoring machine having a combined feeding and scoring roll, on the periphery of which are interlocking segments movable relative to each other, substantially as and for the purpose described.

2. A paper feeding and scoring machine having a combined feeding and scoring roll on the periphery of which are series of interlocking segments, one of the series being movable relative to the other and the segments thereof joined, and carrying, where they are joined, a scoring device, substantially as and for the purpose described.

3. In a paper-feeding machine, a feeding-roll on the periphery of which is a series of segments shiftable on the roll, and interlocking at both ends with other segments on the roll, substantially as and for the purpose described.

4. In a paper-scoring machine, a roll on the periphery of which is a series of segments shiftable on the roll, and united between their ends, and interlocking at both ends with other segments on the roll, substantially as and for the purpose described.

5. In a paper-feeding machine, the combination of a pair of rolls each of which has a variable, peripheral feeding portion formed of interlocking segments, substantially as and for the purpose described.

6. In a paper-feeding machine, the combination of a pair of rolls, each of which has a variable, peripheral feeding portion formed of interlocking segments that carry a scoring device, substantially as and for the purpose described.

7. In a paper-feeding machine, the combination of a pair of rolls, one of which has a non-feeding peripheral portion, and the other has a peripheral portion that comes opposite the latter, which is formed of interlocking segments that are movable relative to each other, substantially as and for the purpose described.

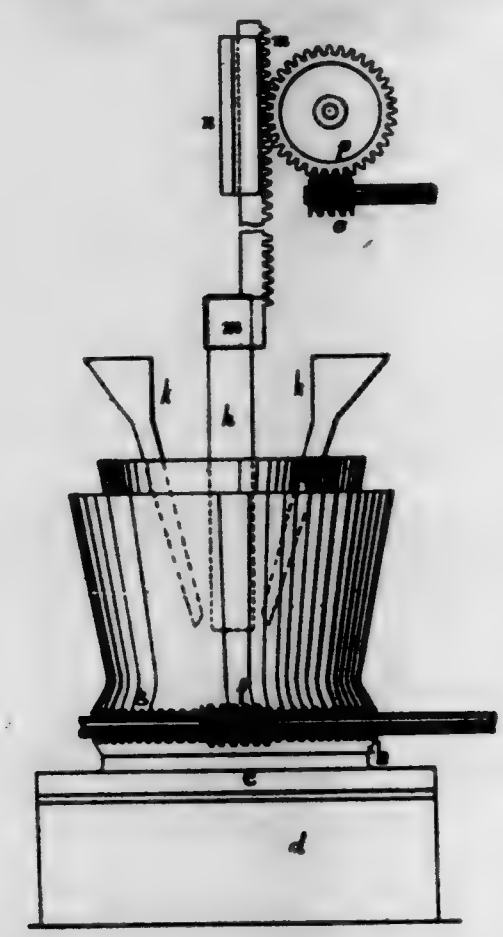
8. In a paper-feeding machine, the combination of intermittently-acting feeding mechanism, comprising coacting parts between which is a space for non-feeding, and a feed-gage located on the side of said feed mechanism opposite that from which paper is fed thereto in position to engage the forward edge of the paper after the same has been passed through said space, substantially as and for the purpose described.

9. In a paper-feeding machine, the combination of a combined feeding and scoring roll having a depressed, non-feeding peripheral portion, and a feed-gage on the side of the roll opposite that from which paper

is fed to the roll, adapted to engage the forward edge of the paper, substantially as and for the purpose described.

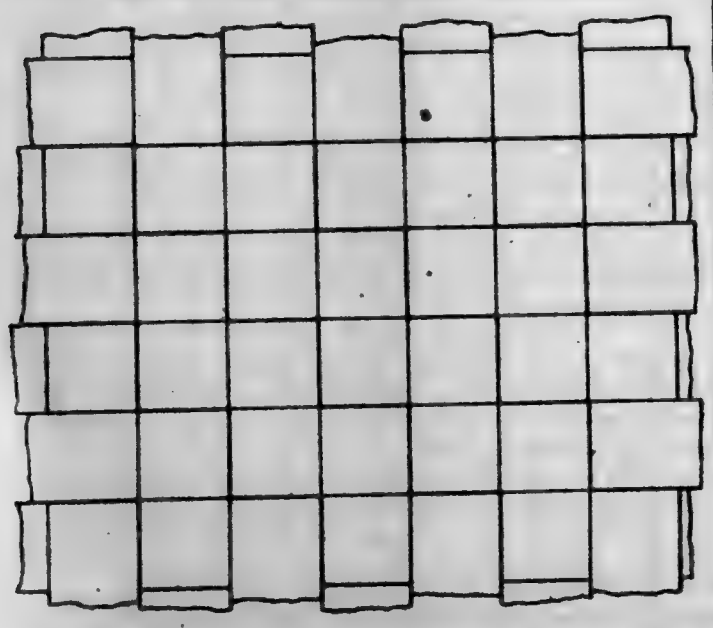
10. In a paper-feeding machine, the combination of a combined feeding and scoring roll having a non-feeding peripheral portion, a feed-gage, and operating means therefor connected with the roll, substantially as and for the purpose described.

706,099. ELECTRIC FURNACE. ARTHUR PARKER, Chorley, England. Filed May 8, 1901. Serial No. 59,231. (No model.)



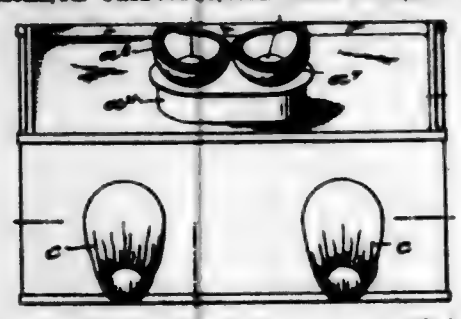
Claim.—In an electric furnace the combination with the crucible *a* and positive-carbon electrode *k* placed diametrically across the crucible, of the rotatable supporting-platform *b*, the recessed base *c*, the supporting-plate *e* in two parts with recess into which the platform-base fits, the worm-wheel *g* around its periphery, the worm *f* gearing with the wheel *g*, the chutes *h* to deliver the material direct into the arc, and mechanism for raising the carbon electrode *k* as the crucible fills substantially as described.

706,100. METAL-FOIL FABRIC. HARRY L. PARKER, El Paso, Tex. Filed Aug. 6, 1901. Serial No. 71,120. (No specimens.)



Claim.—A fabric consisting of strips of metal foil of one or more layers adhering to bands or ribbons made of a textile fabric, and woven, substantially as set forth.

706,101. PORTABLE AND SEPARABLE PHOTOGRAPHIC DEVELOPING-CASE OR DARK CABINET. THOMAS T. PATCHEL, Westchester, Pa., assignor, by mesne assignments, of one-half to George G. Patchel, Media, Pa. Filed Oct. 23, 1901. Serial No. 80,413. (No model.)



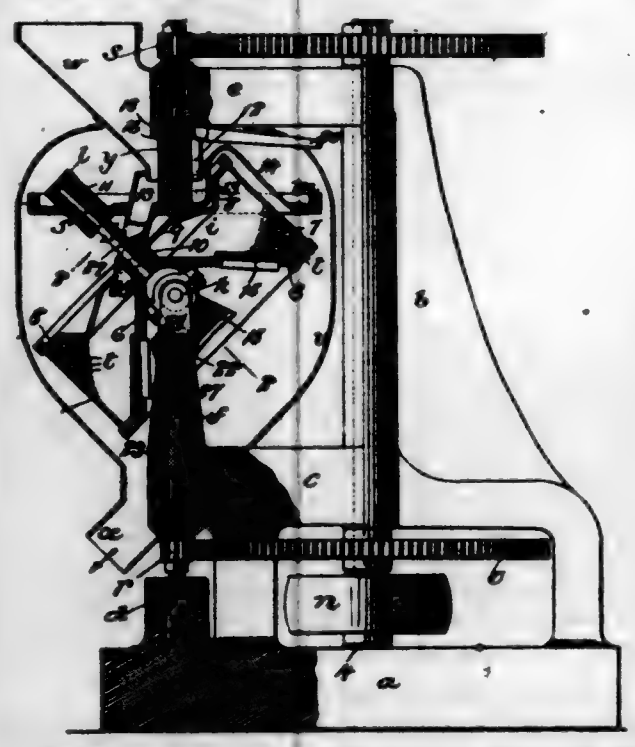
Claim.—1. In a photographic dark room, a separable box provided with an inclined roof having an opening therein, a slide adapted to close said opening, a crown surrounding said opening and carrying peep-holes, detachable eye-guards fitted to said crown, armlets projecting from the front of the box and a detachable slide in one end wall of said box and adapted to close the opening provided in said wall.

2. In a photographic dark room, a separable box, the front wall whereof is provided with openings and the roof whereof is inclined downward toward the front wall and having an opening, a flanged rim surrounding each opening in the front wall, a flexible armlet adapted to detachably engage said flanged rim, a crown inclosing the opening in the inclined roof, two flanges projecting upward from the crown to form peep-holes therein, and detachable eye-guards engaging said flanges of the crown.

3. In a photographic dark room, a separable box, an inclined roof for said box having an opening, a slide arranged within the box and adapted to close the opening in the roof, a crown surrounding the roof-opening and projecting from the exterior of the box, said crown having two openings or peep-holes, a flanged rim surrounding each peep-hole, and an eye-guard detachably connected to each flanged rim.

4. In a photographic dark room, a separable box, comprising a floor, side walls and an inclined roof having an opening, the meeting edges of the walls floor and roof of said box being complementally formed into feathers and grooves, the feathers of certain edges adapted to slide into and out of the grooves of the other complemental edges, a slide arranged to close the opening in the roof, a crown surrounding the roof-opening and having peep-holes, a flanged rim surrounding each peep-hole, and an eye-guard detachably connected to each flanged rim.

706,102. CENTRIFUGAL GRINDING-MILL. JOHN H. PENDLETON, Jamesburg, N. J., assignor to the Pendleton-Topscott Company, New York, N. Y., a Corporation of New Jersey. Filed July 9, 1901. Serial No. 67,005. (No model.)



Claim.—1. In a mill, the combination of a mortar and grinding-balls therein, a shaft which carries said mortar, two shafts alined with each other and between the adjacent ends of which the first-named shaft is obliquely arranged and carried as part of a flexible crank connection, and means for rotating said alined shafts at different velocities, substantially as described.

2. In a mill, the combination of a mortar and grinding-balls therein, a shaft which carries said mortar, two shafts alined with each other and between the adjacent ends of which the first-mentioned shaft is obliquely arranged, a flexible connection between one of said alined shafts and one end of said obliquely-arranged shaft, a crank-arm on the other of said alined shafts, a pivotal connection between said crank-arm and the other end of said obliquely-arranged shaft, and means for rotating the two alined shafts at different velocities, substantially as herein described.

3. In a mill, the combination of a mortar and grinding-balls therein, a shaft which carries said mortar, two shafts alined with each other and between the adjacent ends of which the first-mentioned shaft is obliquely carried, means for rotating said alined shafts at different velocities, and a rotary feeding-spout carried by one of said alined shafts and entering the mortar, substantially as herein described.

4. In a mill, the combination of a mortar and grinding-balls therein, a shaft which carries said mortar, two shafts alined with each other and between the adjacent ends of which the first-mentioned shaft is obliquely arranged, a gimbal-joint between one of said alined shafts and one end of said obliquely-arranged shaft, a crank-arm on the other of said alined shafts, a journal-bearing in said crank-arm receiving a journal on the other end of said obliquely-arranged shaft, and means for rotating the two alined shafts at different velocities, substantially as herein described.

5. In a mill, the combination of a mortar and grinding-balls therein, a shaft which carries said mortar, two shafts alined with each other and between the adjacent ends of which the first-mentioned shaft is obliquely arranged and carried as part of a flexible crank connection, means for rotating said alined shafts at different velocities, and a rotary feeding-spout carried by one of said alined shafts and entering the mortar, substantially as herein described.

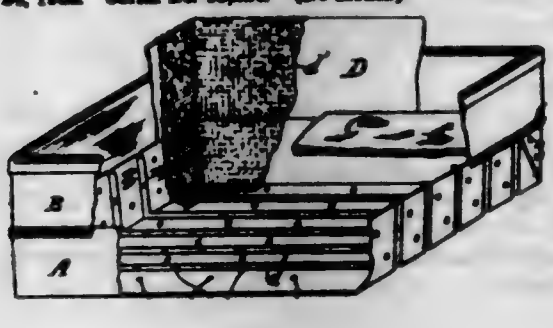
6. In a mill, the combination of a mortar and grinding-balls and screens therein, a shaft which carries said mortar, two shafts alined with each other and by and between the adjacent ends of which the first-mentioned shaft is obliquely arranged as part of a flexible crank connection, means for driving the two alined shafts at different velocities, and a stationary casing surrounding the mortar and the crank connection and having a feeding-inlet above the mortar and a delivery-outlet below the mortar, substantially as herein described.

7. In a mill, the combination of a mortar and grinding-balls therein, a shaft which carries said mortar, two shafts alined with each other and between the adjacent ends of which the first-mentioned shaft is obliquely arranged and carried as part of a flexible crank connection, means for rotating said alined shafts at different velocities, a rotary feeding-spout carried by one of said alined shafts and entering the mortar, and a stationary casing surrounding the mortar and its crank connections and having a feeding-inlet in its upper part communicating with said rotary feeding-spout and a delivery-outlet in its lower part, all substantially as herein described.

706,108. BARREL BUNG AND BUSHING. ELWOOD C. PHILLIPS, Chicago, Ill., assignor of one-fourth to Oscar A. Schaffer, Chicago, Ill. Filed June 11, 1900. Serial No. 19,868. (No model.)

Claim.—In a barrel bung or bushing of the character herein described, the combination of a stationary bushing formed with a lower inturned margin or seat, a rotatable plug fitting said bushing and provided on its lower end with an integrally-formed stud having a cylindrical shank headed at its lower end, and an elastic disk arranged on the under surface of said plug, and a centrally-arranged enlargement protruding beyond the lower face of the disk and in which is formed a cavity adapted to engage the headed attaching-stud, the bottom of said cavity being closed so as to prevent leakage around and through the metal portions of the bung and bushing, substantially as set forth.

706,104. CHEESE-HOOP. EDWARD J. PRESCOTT, Chicago, Ill. Filed Feb. 24, 1902. Serial No. 96,292. (No model.)

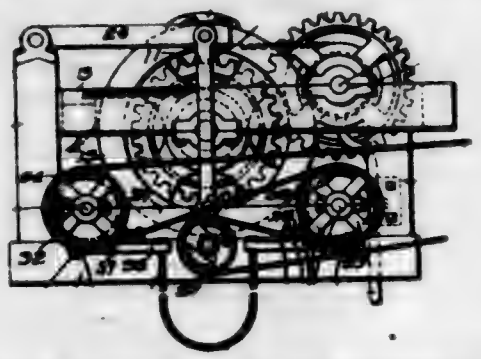


Claim.—1. A cheese-hoop comprising a rectangular-shaped main portion and a series of hollow and perforated ribs located on the inner surface of its bottom and walls, substantially as described.

2. A rectangular cheese-hoop having on its inner surface a series of hollow and perforated ribs, substantially as described.

3. A cheese-hoop comprising a rectangular-shaped main portion struck up and having formed integrally therewith a series of perforated ribs, substantially as described.

706,105. DRIVING MECHANISM FOR HOISTING AND CONVEYING APPARATUS. WILLIAM F. PILLSBURY and DAVID ANDERSON, Westerville, N. Y. Filed Dec. 22, 1900. Serial No. 40,830. (No model.)



Claim.—1. In a reversing apparatus, the combination of a power-wheel, a brake normally applied thereto, opposite drive-wheels supported by the brake and constructed for alternate engagement with the power-wheel, and means for automatically removing the brake by the application of either drive-wheel.

2. In a power-controlling device, the combination with a power-wheel, of a drive-wheel normally out of engagement therewith, a brake supporting the drive-wheel and normally in engagement with the power-wheel, means for applying and removing the drive-wheel with respect to the power-wheel and a connection between the drive-wheel and the brake constructed for automatically removing the latter by the application of the former.

3. In a power-controlling device, the combination with a power-wheel, of a normally applied brake therefor, a drive-wheel normally out of engagement with the power-wheel and supported solely by the brake whereby the latter is normally applied, and means for applying the drive-wheel to the power-wheel and removing the brake through the connection between the latter and the drive-wheel.

4. In a power-controlling device, the combination with a power-wheel, of a normally applied brake therefor, a rocker supported solely by the brake whereby the latter is normally applied, opposite drive-wheels mounted upon the opposite end portions of the rocker, means for operating the rocker to alternately apply the drive-wheels to the power-wheel, and opposite fulcrum-supports for the rocker.

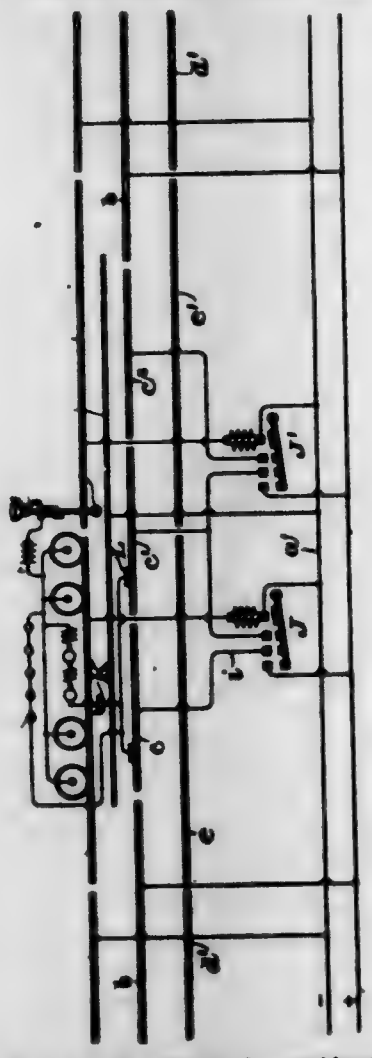
5. In a power-controlling device, the combination with a power-wheel, of a normally applied brake therefor, a rocker pivotally hung at its middle from the brake whereby the latter is normally applied, drive-wheels mounted upon the opposite end portions of the rocker and constructed for alternate engagement with the power-wheel, means for tilting the rocker upon its pivotal support to apply either drive-wheel to the power-wheel, and fulcrum-supports for the rocker located at opposite sides of the middle pivotal support and constructed for alternate engagement by the rocker in its opposite tilting movements to force the brake from the power-wheel.

6. In a power-controlling device, the combination with a power-wheel, of an intermediately-fulcrumed rocker, drive-wheels mounted upon the opposite end portions thereof and constructed for frictional engagement with the power-wheel, and opposite levers operatively connected to the respective ends of the rocker and constructed to tilt the latter and alternately apply the drive-wheels to the power-wheel.

7. In a power-controlling device, the combination with a frame, of a power-wheel mounted thereon, a brake-lever pivoted to the frame and having a shoe normally applied to the power-wheel, a rocker pivotally supported at its middle upon the brake-lever, whereby the weight of the rocker normally applies the brake, pairs of belt and drive wheels mounted upon the opposite end portions of the rocker, the drive-wheels being constructed for engagement with the power-wheel, a continuous drive-belt passed in opposite directions about the belt-wheels, means for tilting the rocker in opposite directions upon its pivotal support, and opposite fulcrum-supports carried by the frame at opposite sides of the pivotal support of the rocker and constructed for alternate engagement by the rocker in its opposite tilting movements, whereby the brake is forced out of engagement with the power-wheel when either drive-wheel is applied thereto.

8. In a power-controlling device, the combination with a frame, of a power-wheel mounted thereon, a brake hinged to the frame and normally applied to the power-wheel, a rocker pivotally hung at its middle from the brake and adjacent to the upper side of one of the frame-bars, the weight of the rocker normally applying the brake, operatively-connected pairs of belt and drive wheels mounted upon the opposite end portions of the rocker, the drive-wheels being constructed for alternate engagement with the power-wheel, a continuous drive-belt passed in opposite directions about the belt-wheels, lateral fulcrum projections carried by the rocker at opposite sides of its middle and constructed for alternate engagement with the adjacent frame-beam, and opposite levers fulcrumed upon the frame, and having operative connections with the respective ends of the rocker to tilt the same in opposite directions.

706,106. ELECTRIC RAILWAY. WILLIAM R. POTTER, Schenectady, N. Y., assignor to the General Electric Company, a Corporation of New York. Filed Nov. 18, 1896. Serial No. 612,648. (No model.)



Claim.—1. In an electric railway, the combination of a third-rail conductor the continuity of which is interrupted at stations or other predetermined points, sectional conductors at the points of interruption, traffic-rails divided electrically into sections at the points of interruption, and energizing-coils for circuit-closing switches permanently included in circuit between the traffic-rail sections and the negative conductor; the arrangement being such that the coils are energized by the main-line current after it has passed through the propelling motor or motors.

2. In an electric railway, the combination of a third-rail conductor the continuity of which is interrupted at stations or other predetermined points, sectional power-conductors substituted at the points of interruption, insulated sections of the traffic-rails also located at the points of interruption of the third rail or conductor forming energizing-conductors, switches for closing the circuit between the power-sections and the source of supply, and energizing-coils for the switches permanently included in circuit between the sectional traffic-rails and the negative conductor, the arrangement being such that the coils are energized by the main-line current after it has passed through the propelling motor or motors.

3. In an electric railway, the combination of a vehicle, a sectional power-conductor normally disconnected from the source of supply, a continuous conductor extending parallel with the sectional conductor but forming no part of the motor-circuit, a battery, electromagnetic switches for closing the circuit between the source of supply and the sectional conductor, and means for including the battery in circuit with said conductor and the energizing-coils of the switches for closing the circuit of the sectional conductor.

4. In an electric-railway system, the combination of a third rail or conductor for supplying current to the motors and lighting-circuit, the continuity of which is interrupted at certain points, a sectional conductor substituted at the point of interruption, a feeder and means for transferring the lighting-circuit from the third rail to the sectional conductor.

5. In an electric-railway system, the combination of a third rail or conductor for supplying current to the motors and lighting-circuit, the continuity of which is interrupted at certain points, a sectional conductor substituted at the point of interruption, a feeder, means for transferring the lighting-circuit from the continuous third rail to the sectional conductor, switches for including the sectional conductors in circuit with the feeder, and means for maintaining the circuit after the supply of current to the motors ceases.

6. In an electric railway, the combination of a third rail or conductor, the continuity of which is interrupted at certain points, a sectional conductor substituted therefor at the point of interruption, traffic-rails also divided into sections at the point of interruption of the third rail, and a conductor permanently grounded extending parallel with the sectional conductor, and approximately equal in length to the space between the ends of the third rail.

7. In an electric railway, the combination with the positive and negative main wires or cables, of power-conductor sections, electromagnetically-operated switches for connecting the latter with the positive main, insulated track-sections, connections including switch-operating coils between the track-sections and the negative main, whereby the switches are operated by current flowing from the motors, an independent or auxiliary source of current carried by the car and adapted to be connected with the track-rails, and an auxiliary road-conductor connected to the negative main, and over which conductor a circuit is established to initially energize a switch-magnet.

8. In an electric railway, the combination with the feeder, of a power-conductor permanently connected therewith but interrupted at desirable locations, power-conductor sections between the adjacent ends of the interrupted conductor and normally disconnected from the feeder, collecting means on the car, electromagnetic switches adapted to connect said sections with the feeder as the car is driven forward, and a device on the car adapted to be operated manually to close said switches when insufficient current is flowing through the collecting means, said device being automatically rendered inoperative as the car proceeds.

9. In an electric railway, the combination with the feeder, of a sectional power-conductor, a collector carried by the car, car-motors, connected with the collector, a controller for the motors, translating devices in parallel with the motors, electromagnetic switches for connecting the power-conductor sections with the feeder while sufficient current is flowing through the collector, but tending to open when the current falls off, and an auxiliary means for maintaining said switches closed when the current flowing through the collector is insufficient.

10. In an electric railway, the combination with the feeder, of a power-conductor permanently connected with the feeder, and interrupted for a considerable space at locations where it is undesirable to have the power-conductor continuously alive, power-conductor sections in such space and normally disconnected from the feeder, a collector, electromagnetic switches adapted to be closed to connect said sections with the feeder while sufficient current is flowing through the collector, but tending to open when such current falls off, and auxiliary means for closing said switches when the current flowing through the collector is insufficient.

11. In an electric railway, the combination with the feeder, power-conductor sections, electromagnetically-operated switches for connecting the latter with the former, energizing-conductor sections connected with the magnet-coils of the switches, a traveling collector on the car for collecting current for the motors from the power-conductor section, traveling conductors on the car connected with the motors and engaging the energizing-sections, and an auxiliary traveling contact carried by the car for opening the switches when current is cut off from the car-motors.

12. In an electric railway, the combination with the feeder, of auxiliary conductor-sections, a collector carried by the car for engaging said conductor-sections, electromagnetic switches adapted to be closed by current flowing through the collector to connect the power-conductor sections with the feeder as the car progresses, a road-conductor independent of said conductor-sections, which is connected with the coils of said switches, a source of electricity on the car, and a contact device connected with said source and adapted to engage said road-conductor to energize said switches when they open owing to a leak of current flowing through the collector.

13. In an electric railway, the combination with the positive and negative mains, of conductor-sections, electromagnetic switches for connecting the latter with the former, the switch-coils being connected between the negative main and conductor-sections, an independent or auxiliary source of current adapted to be connected with a conductor-section, and an auxiliary road-conductor independent of said conductor-sections, which is connected to the negative main, whereby when the auxiliary

source is connected also with the auxiliary conductor, a circuit will be established through a switch-magnet.

14. In an electric railway, the combination with the feeder, of a sectional power-conductor, electromagnetic switches for connecting the sections of the latter with the former, an auxiliary or pick-up sectional conductor arranged parallel to the sectional power-conductor, each section of said auxiliary conductor being connected to but one switch-magnet coil, and collectors carried by the car, the relative arrangement of the sectional conductors and collectors being such that a section of the auxiliary conductor is engaged by a collector, in either direction of movement of the car, before the power-section, which is thereby energized, is engaged by its collector.

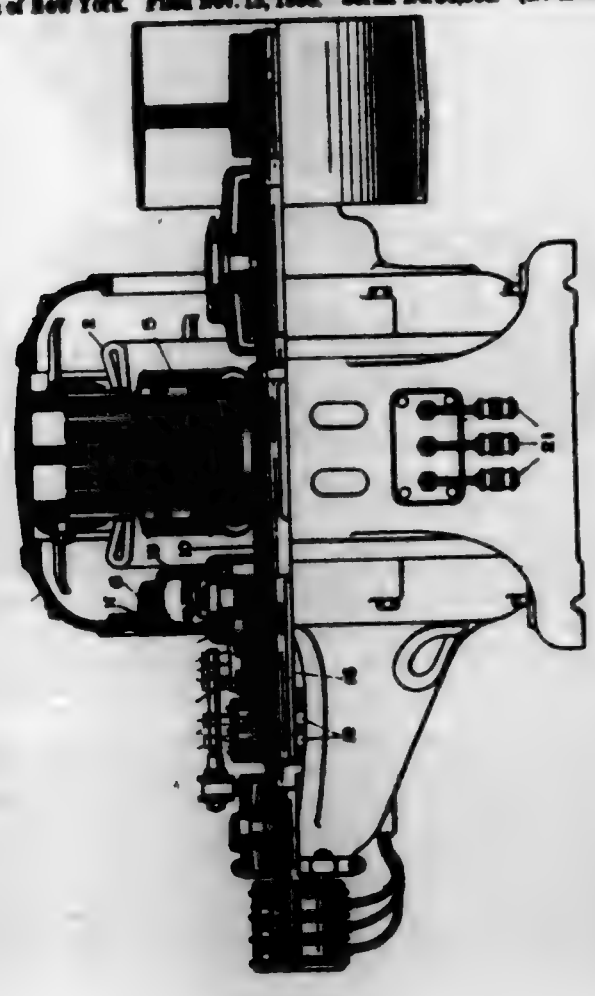
15. In an electric railway, the combination with the feeder, of a sectional power-conductor, electromagnetic switches connecting the former with the latter, a sectional auxiliary or pick-up conductor arranged parallel to the power-conductor, each section of the auxiliary conductor being connected with but one switch-magnet coil, and the sections of the power and auxiliary conductor overlapping with respect to each other, whereby each power-conductor section is connected to the feeder in advance of the collector.

16. In an electric railway, the combination with the feeder, of a sectional power-conductor, electromagnetic switches for connecting the sections of the latter with the former, an auxiliary or pick-up conductor located parallel to the sectional power-conductor, a section of the auxiliary power-conductor being connected to the magnet-coils of the switch, a switch being connected to two power-sections, a power-section being connected to two switches; and collectors carried by the car, the relative arrangement of the power and auxiliary sections and the collectors being such that a switch is closed to enliven two power-sections before the collector has engaged with either of such power-sections.

706,107. FRUIT-KNIFE. CHARLES W. PERRYMAN, Antrim, N. H., assignor to Goodell Company, Antrim, N. H. Filed Mar. 1, 1902. Serial No. 96,261. (No model.)

Claim.—A fruit-knife having a curved cutting front edge, and a curved blunt back edge, and a sharp point, and having on the blunt edge, near the point, a short sharpened parting-blade at an angle with the blunt back, and lying in the same plane with the blade proper, substantially as described.

706,108. DYNAMO-ELECTRIC MACHINE. HENRY G. REIST, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Nov. 13, 1900. Serial No. 36,348. (No model.)



Claim.—1. The combination of an internal revolving-field alternator, an exciter or regulating-machine therefor having its armature synchronously rotatable with the revolving-field member of the alternator, collector-rings connected to said armature, and other collector-rings connected with said revolving-field member.

2. The combination of an internal revolving-field alternator, an exciter or regulating-machine therefor having its armature mounted on the same shaft as the revolving-field member of the alternator, and means for angularly adjusting the field of the exciter.

3. A dynamo-electric machine consisting of a main machine and an exciter therefor with the revolving members of each mounted on the same shaft, and means for moving the field of the exciter relatively to the fixed member of the main machine.

4. The combination of a main machine, a synchronously-driven exciter therefor, and means for adjusting the exciter-field relatively to the fixed member of the main machine.

5. The combination of a main machine, an exciter therefor having a field-magnet structure provided with pole-pieces, bridges of magnetic material extending between said pole-pieces, and means for adjusting the exciter-field relatively to the fixed member of the main machine.

6. A compounded alternator consisting of a main machine of the revolving-field type, an exciter or regulating-machine therefor having its armature and commutator mounted on the same shaft as the revolving member of the main machine, collector-rings connected to points in the winding of said armature, and other collector-rings connected to the winding of the revolving field of the main machine.

7. A compounded alternator consisting of a main machine of the revolving-field type, an exciter or regulating-machine therefor having its armature and commutator mounted on the same shaft as the revolving member of the main machine, collector-rings connected to points in the winding of said armature, other collector-rings connected to the winding of the revolving field of the main machine, and a rigid supporting structure or frame for carrying the fixed members of both machines.

8. A compounded alternator comprising a main machine, an exciter therefor, a single shaft upon which the revolving member of the main machine and armature of the exciter are both mounted, and means for shifting the field structure of the exciter relatively to the fixed portion of the main machine.

706,109. WHIFFLETREE ATTACHMENT. NICHOLAS REIMER, Hawkeye, Iowa. Filed Feb. 8, 1902. Serial No. 93,154. (No model.)

Claim.—The herein-described securing device for singletrees or the like, comprising a suitable anchoring-thimble 2, a hook 3 attached to the outer end of said thimble and having its free end directed inward; a housing 5 carried by said thimble having a pivoted detent 7 adapted to engage the free end of said hook; a spring adapted to hold the outer end of said detent in engagement with said hook and a pivoted detent having an operating handle or crank adapted to engage the locking-detent and hold the same against inward movement whereby the tug or trace-chain will be reliably locked in engagement with the said hook until it is desired to release the same, all operatively combined substantially as specified and for the purpose set forth.

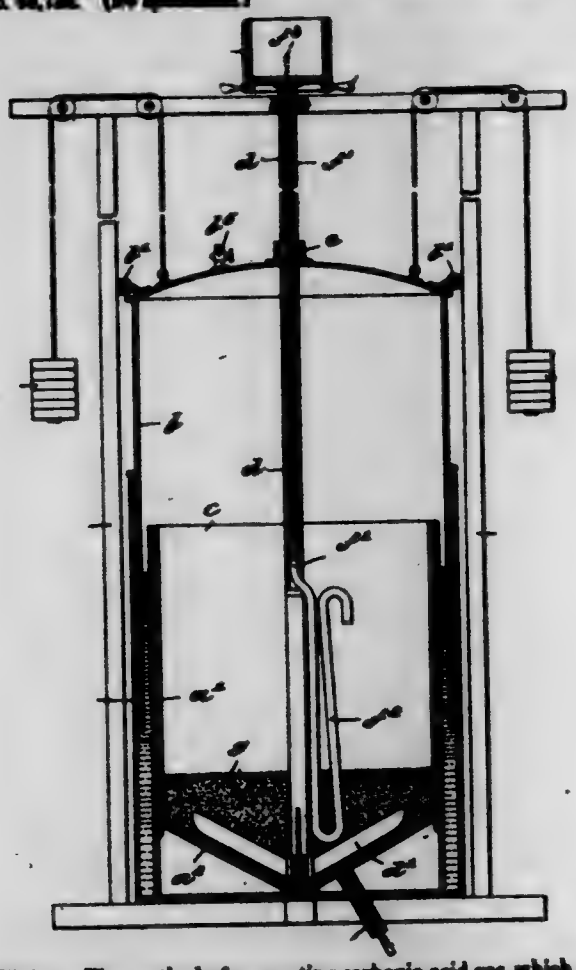
706,110. TOY. FRANK D. REITZEL, Cincinnati, Ohio. Filed Feb. 3, 1902. Serial No. 92,206. (No model.)

Claim.—1. A representation of a human figure jointed so as to be capable of assuming either an upright or a sitting position, a seat for the figure and a support for it extending forwardly from the seat and on which it may be guided and moved bodily in a substantially horizontal direction

to or from such seat, the figure assuming a sitting position when coming in contact with the seat and assuming an upright position when being moved away therefrom.

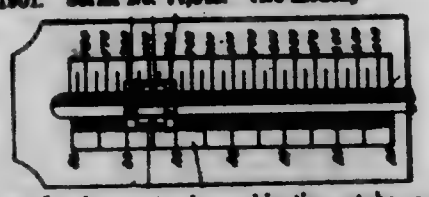
2. In a toy, the combination of a seat, a figure and a support for this latter extending forwardly from the seat in a substantially horizontal direction and on which the figure may be moved between fixed limits to or from the seat, this latter forming the limit of the movement in a rearwardly direction.

706,111. METHOD OF MAKING CARBONIC-ACID GAS. VAN VECHTEN W. EMMENS, Philadelphia, Pa. Filed July 13, 1901. Serial No. 68,736. (No specimens.)



Claim.—The method of generating carbonic-acid gas, which consists in, first, introducing a charge of carbonaceous material into a receptacle; second, in forming in the receptacle a partial vacuum; third, introducing acid continuously to the carbonaceous material after the vacuum has been formed, and, finally, increasing the capacity of the receptacle as the gas is generated, to thereby maintain the gas under low pressure.

706,112. BAROMETER. ALFRED L. ROSSIUS, Chicago, Ill. Filed Sept. 30, 1901. Serial No. 77,063. (No model.)



Claim.—1. In a barometer, in combination, a tube; a barometric column in said tube; a bracket having a shoulder for supporting said tube, also having an elongated opening in its upper end; a clip adapted to guide said bracket; and a thumb-screw extending through a threaded opening in said clip for engaging said bracket to bodily raise and lower said tube to provide for the expansion and contraction of said column.

2. In a barometer, in combination, a base; a barometric tube bent to form a long and a short leg, said short leg being provided with a cistern having an open upper end; a mercurial column in said tube; keeps on said base for slidably supporting the long leg of said tube; a mirror secured to said base behind said cistern, said mirror having a zero-mark, a bracket for supporting said tube at the point of juncture of its legs; and a screw for moving said bracket to adjust said column with reference to said zero-mark.

3. In a barometer, in combination, a barometric tube; an integral cistern having an open upper end, said cistern communicating at its lower end with one end of said tube and being formed integral with said tube; a barometric column in said tube; and a closure for said cistern, comprising a portion adapted to tightly engage the open upper end of said cistern, and a body portion composed of elastic material adapted to contain a quantity of mercury.

4. In a barometer, in combination, a barometric tube bent to form a long and a short leg, said short leg being provided with a cistern formed integral therewith, said cistern having an open upper end; a mercurial column in said tube; and a closure for said cistern, comprising an elastic tube adapted to contain a quantity of mercury, and to be secured by one of its ends to the upper end of said cistern.

5. In a barometer, in combination, a barometric tube having a cistern at its open end formed integral with said tube; a barometric column in said tube; an elastic closure for said cistern adapted to be secured over the open end thereof; and means for bodily adjusting the barometric tube to provide for the expansion and contraction of said barometric column.

6. In a barometer, in combination, a barometric tube having a cistern at its open end formed integral with said tube; a barometric column in said tube; an elastic closure for said cistern adapted to be secured over the open end thereof; a bracket for supporting said tube; and means for moving said bracket in a vertical direction to provide for the expansion and contraction of said column.

7. A vernier for barometers, having two scales for different systems linear measurement, and a spring for holding said scales in frictional engagement with a portion of the barometer upon which it is mounted.

8. A vernier for barometers, having two scales for different systems of linear measurement, and two loops for holding said scales together and for engaging the barometric tube for frictionally holding said vernier in engagement with a portion of the barometer upon which it is mounted.

706,118. KINETOGRAPHIC APPARATUS. ALVAN C. ROSSOCK and FRANK MCMILLAN, Chicago, Ill. Filed Mar. 22, 1900. Serial No. 9,947. (No model.)

Claim.—1. In a kinetographic apparatus, the combination of a closed casing provided with an objective at one side and with passages at top and bottom for the passage of a pictured film, a film-feeding mechanism arranged within said casing, a door forming the opposite side of the casing and adapted to maintain the film at the proper focal plane, a vertical pivot-pintle securing the door to the casing, a supporting-standard having connection with said casing at the side at which the door is hinged, and adapted to provide an open-sided passage beneath the casing, substantially as set forth.

2. In a kinetographic apparatus, the combination of a closed casing provided with an objective at one side and with passages at top and bottom for the passage of a pictured film, a film-feeding mechanism arranged within said casing, a door forming the opposite side of the casing and adapted to maintain the film at the proper focal plane, a vertical pivot-pintle securing the door to the casing, a vertically-adjustable sash arranged upon said door and provided with a framing-opening, a supporting-standard having connection with said casing at the side at which the door is

hinged and adapted to provide an open-sided passage beneath the casing, substantially as set forth.

3. In a kinetographic apparatus of the character herein described, the combination of a main casing, a door adapted to maintain the picture-frame at the focal plane, a vertically-sliding sash arranged to move in guides on said door and provided with a picture-framing opening, and a crank-disk journaled in the door and provided with a crank-pin having operative engagement with the sash, substantially as set forth.

4. In a kinetographic apparatus, the combination of a closed casing provided with an objective at one side and with passages at top and bottom for the passage of a pictured film, a film-feeding mechanism arranged within said casing, a door forming the opposite side of the casing and adapted to maintain the film at the proper focal plane, a vertical pivot-pintle securing the door to the casing, a bearing-roller journaled on said door and adapted to hold the film in engagement with the feeding mechanism, and a spring tending to force said roller toward such film-feeding mechanism, substantially as set forth.

5. In a kinetographic apparatus, the combination of a closed casing provided with passages at top and bottom for the passage of a pictured film, a film-feeding mechanism arranged within said casing, a door hinged at one side of said casing on a vertical pivot-axis and forming one side of the casing, and adapted to maintain the film at the proper focal plane, a supporting-standard having connection with said casing at the side at which the door is hinged, an initial film-feeding mechanism journaled wholly at one end to such supporting-standard, and adapted in connection with said door to admit of a ready removal and replacement of the film in the film-changing operation, substantially as set forth.

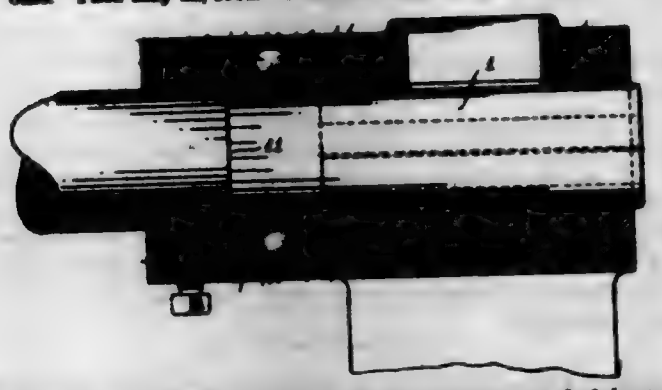
6. In a kinetographic apparatus, the combination of a closed casing provided with passages at top and bottom for the passage of a pictured film, a film-feeding mechanism arranged within said casing, a door hinged at one side of said casing on a vertical pivot-axis and forming one side of the casing and adapted to maintain the film at the proper focal plane, a supporting-standard having connection with said casing at the side at which the door is hinged, an initial film-feeding mechanism journaled wholly at one end to such supporting-standard, a horizontal arm secured to said standard, and an auxiliary film-feeding mechanism journaled wholly at one end on said horizontal arm, substantially as set forth.

7. In a kinetographic apparatus of the character herein described, the combination with the film-carrying reel, of a supporting-arbor for such reel, and a combined attaching means and frictional connection between such reel and arbor, the same comprising a spring-finger carried by the reel, and a circumferential groove in said arbor adapted to receive said spring-finger, substantially as set forth.

8. In a kinetographic apparatus of the character herein described, the combination with the main casing, of a swinging door for the same, and a horizontal rod extending transversely across the casing and provided with a catch to engage the free end of the door, substantially as set forth.

9. In a kinetographic apparatus of the character herein described, the combination with the main casing, film-feeding roller and a revolving shutter, of a driving-shaft forming a journal for the feeding-roller and revoluble independent of such roller, a gear-wheel on the driving-shaft, a gear-wheel on the shutter-shaft gearing with said gear-wheel, and gearing connection between the shutter and the film-feeding roller, adapted to impart intermittent motion to said roller, substantially as set forth.

706,114. BALL THRUST-BEARING. ALBERT RUDY, Toledo, Ohio. Filed May 22, 1902. Serial No. 108,658. (No model.)



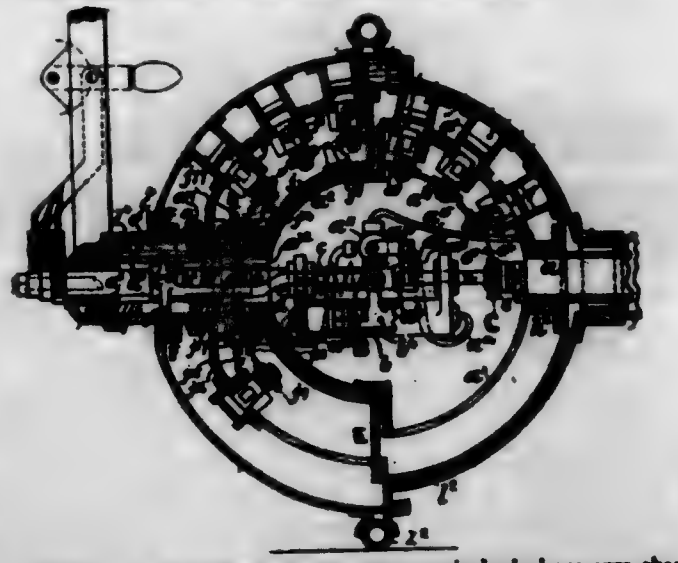
Claim.—In a ball thrust bearing, the combination of a shaft having a reduced end portion forming a shoulder; a bearing having a socket or bore to receive the end of the shaft, there being a bearing-face around the socket or bore of the bearing, and a pin projecting from the face; a flat-faced bearing-ring mounted on the shaft and provided with a socket on one side to receive the pin of the bearing, a collar having one side faced and provided with a pin projecting from the face, mounted and secured on the shaft with its face concentric and flush with the face of the shoulder of the shaft; a flat-faced bearing-ring mounted on the shaft having an aperture in one face adapted to receive the pin of the collar; a flat-faced ball cage-ring having cylindrical ball-apertures transverse through the sides and in a circle concentric around the bore of the ring mounted on the shaft between the bearing-rings and balls in the apertures having greater diameter than the thickness of the cage, substantially as shown and described.

706,115. APPARATUS FOR CARBONATING LIQUIDS. ARI RELF, Brussels, Belgium. Filed Aug. 9, 1901. Serial No. 71,462. (No model.)

Claim.—1. In a carbonating apparatus, the combination of an inclosed casing having a discharge-outlet for the carbonated liquid and inlets for the gas and the liquid to be carbonated, a plurality of concentric annular tubes arranged in said casing, communicative connection between said tubes and the liquid-inlet, and concentric cylindrical bodies alternating with said tubes and each open at one end, said tubes and the cylindrical bodies being arranged in close proximity to each other and the former being perforated adjacent said cylindrical bodies, substantially as described.

2. In a carbonating apparatus, the combination of an inclosed casing having a discharge-outlet at the bottom for the carbonated liquid and inlets for the gas and the liquid to be carbonated, a plurality of concentric annular tubes arranged in said casing, communicative connection between said tubes and the liquid-inlet, concentric cylinders alternating with said tubes and each open at one end, said tubes and the cylinders being arranged in close proximity to each other and the former being perforated adjacent said cylinders, and a perforated support serving as a seat for the lower ends of said cylinders, substantially as described.

706,116. ROTARY MOTOR. ROBERT C. SAYER, Bristol, England. Filed Sept. 30, 1901. Serial No. 77,112. (No model.)



Claim.—1. In fluid-pressure motors a cuneiphorical pressure-chamber formed by an enlargement of the fixed axis, a series of nozzles or passages carried on and exterior to the pressure-chamber, a valve carried by and in the pressure-chamber, a means for actuating the valve through

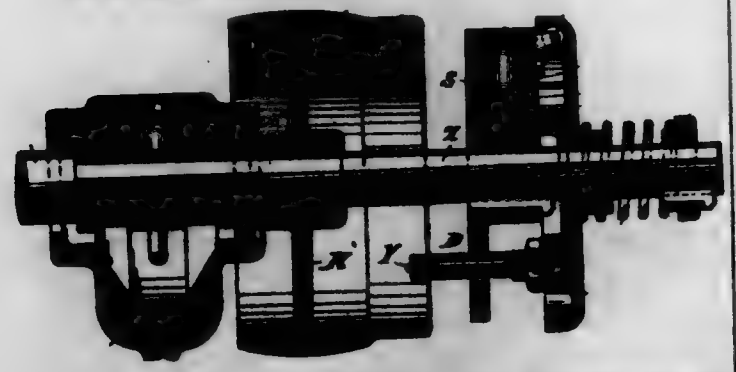
the fixed axle from outside it for the valve to admit the pressure to the nozzles, a rotary element outside the pressure-chamber carried on proper bearings on the fixed axle, a series of vanes or buckets inside the rotary element and formed to receive jets of fluid from the nozzles or passages and be rotated by it; corrugated packings to prevent the pressure from escaping until the point of exhaust, a passage for the exhaust-pressure to pass between the rotary element, the pressure-chamber, and fixed axle, spiral pipe-coils to subdivide the exhaust-passage and a means for supplying the spiral pipe-coils with water or air, substantially as described.

2. A fluid-pressure motor comprising a fixed axle, a pressure-chamber formed by an enlargement of the fixed axle at an intermediate part of its length, a series of nozzles or passages carried on and exterior to the pressure-chamber, valves arranged in pairs in the pressure-chamber, a means for operating either valve of a pair to open while the other is closed to admit the fluid under pressure to either of a series of oppositely-directed nozzles to rotate the motor in either the forward or backward direction, a rotary element mounted outside the pressure-chamber on bearings on the fixed axle, and a series of vanes or buckets fixed inside the rotary element and adapted to receive the jets of fluid from the nozzles or passages, the valves, nozzles, and vanes or buckets, being arranged in series at different vertical distances from the center line of the axle, substantially as described.

3. In fluid-pressure motors the combination with a semispherical pressure-chamber and an outer rotary element adapted to be driven therefrom, of a semispherical auxiliary fluid-pressure chamber attached to the rotary element of the said motor, ports or openings through which the pressure in the axle pressure-chamber of the said motor can pass to the auxiliary pressure-chamber of the rotary element, valves in the said pressure-chamber disposed like those of the said motor, a means through and outside the fixed axle for actuating the valves, series of nozzles or passages outside the auxiliary pressure-chamber adapted to admit the pressure to and act and react against vanes or buckets fixed upon and within the concentric superimposed outer rotary element able to rotate on proper bearings directly or indirectly upon the fixed axle of the said motor, packing to prevent escape of the pressure and a passage in communication with the atmosphere to carry off the exhaust-pressure with dividing-pipes substantially as described.

4. In fluid-pressure motors having two or more concentrically-mounted rotors able to rotate on a fixed axle, keyways in the two rotors, and the fixed axle, and an annular passage in the axle in which a key may rotate with the one rotor or both so that in a center position the key connects the rotors and rotates in a side position the key frees the rotors and rotates; and the other side position it connects the fixed axle and its adjacent rotor; means for traversing the key by a ring on arms and a sleeve; means for traversing the sleeve on a tube against a spring secured to an arm on a rod having a piston each end within an elastic fluid-pressure cylinder in the axle pressure-chamber; a tap and pipes to send pressure to both ends of the cylinder, or retain it at either end and exhaust the other end, and a means for actuating the tap through and from outside the axle, substantially as described.

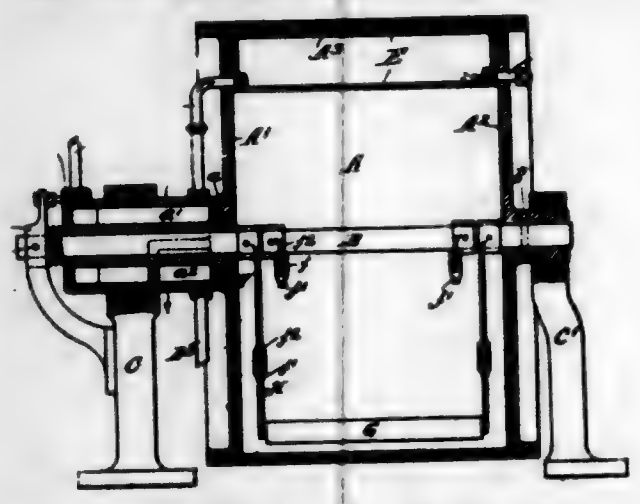
706,117. CLUTCH FOR INDUCTION-MOTORS. ALFRED SCHWARTZ, Munich, Germany, assignor to Helios Electricitäts-Aktiengesellschaft, Cologne-Ehrenfeld, Germany. Original application filed Mar. 18, 1901, Serial No. 51,736. Divided and this application filed Oct. 28, 1901. Serial No. 80,290. (No model.)



Claim.—1. In a clutch for induction-motors, the combination with a journal, of a belt-pulley mounted on the journal and provided with an extended cylindrical wall, an interior wall or partition in said pulley, a disk mounted to slide on the journal, radially-movable clutch-jaws carried by said disk, rollers carried by and extending outwardly from said jaws, means adapted to engage said rollers for holding said jaws in the retracted position, and means for engagement with the interior wall of the pulley to release the retaining means whereby said jaws engage the extended cylindrical wall of the pulley, substantially as described.

2. In a device of the character described, the combination with the journal, of a belt-pulley mounted thereon and provided with an interior wall or partition, a disk mounted for longitudinal movement on said journal, radially-movable jaws carried by said disk, rollers carried by said jaws, a spring-pressed retainer mounted on said journal for engagement with the rollers to normally hold said jaws in the retracted position and means for engagement with the interior wall or partition of the pulley to disengage the retainer from the pulleys, as and for the purpose specified.

706,118. COMBINED TEMPERING-VAT, CHURN, AND BUTTER-WORKER. PHILIP H SHARPLES, Westchester, Pa. Filed Jan. 16, 1900. Serial No. 1,852. (No model.)



Claim.—1. A combined tempering-vat, churn, and butter-worker comprising a rotary vessel having a series of paddles, means for circulating liquid through said paddles and one or more working devices within said vessel adapted to be operated by the rotation of the latter.

2. A combined tempering-vat, churn, and butter-worker comprising a rotary vessel having a series of paddles, means for circulating liquid through said paddles during the rotation of the vessel, working devices within said vessel adapted to be operated by the rotation of the latter, and means for locking said working devices.

3. A combined churn and butter-worker comprising a rotary vessel having a series of paddles, and one or more working devices mounted on fixed pivots within the vessel and arranged to be raised by a passing paddle and thereafter to fall in the path of a succeeding paddle.

4. A combined churn and butter-worker comprising a rotary vessel having a series of paddles, and working devices mounted on fixed pivots within the vessel and arranged to be raised by each passing paddle and thereafter to fall in the path of a succeeding paddle, the swing of said working devices being first toward and then away from the wall of the vessel.

5. A combined churn and butter-worker comprising a rotary vessel having a series of paddles and one or more working devices eccentrically pivoted within the vessel and arranged to swing between adjacent projecting paddles of the rotating vessel in an arc of reduced radius approximately tangent to the wall of the vessel substantially as set forth.

6. A combined churn and butter-worker comprising a rotary vessel having a series of paddles, one or more working devices eccentrically pivoted within the vessel and arranged to swing between adjacent projecting paddles of the rotating vessel in an arc of reduced radius approximately tangent to the wall of the vessel, and stops to limit said swing substantially as set forth.

7. A combined churn and butter-worker comprising a rotary vessel having a series of paddles, one or more working devices eccentrically pivoted within the vessel and arranged to swing approximately at a tangent to the wall thereof, and means for attaching said pivoted devices to the vessel so as to be fixedly rotated therewith, substantially as set forth.

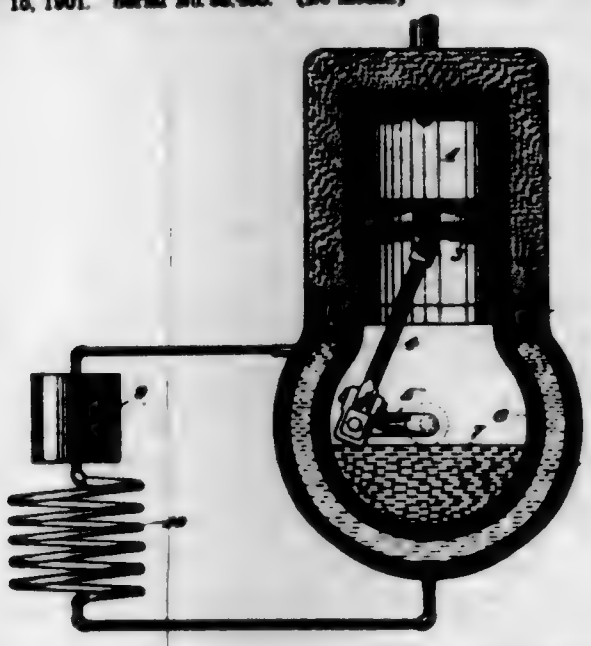
8. A combined churn and butter-worker comprising a rotary vessel having a series of paddles, a shaft having fixed thereto one or more carrying-arms, working devices connected to said arms so as to be capable of a limited swinging movement thereon, and means for rigidly attaching said shaft with its connections to the rotary vessel when desired substantially as described.

706,119. PAINT. JAMES C. SHAW, WILLIE J. SHAW, and ROBERT E. SHAW, Bessemer, Ala. Filed Mar. 11, 1902. Serial No. 97,764. (No specimens.)

Claim.—1. The herein-described paint, consisting of coal-tar, creosote, linseed-oil, asphaltum varnish, and fine salt, substantially as described and for the purpose specified.

2. The herein-described paint, consisting of, coal-tar thirty-six gallons, creosote eight gallons, linseed-oil two gallons, asphaltum varnish two gallons, and fine salt ten pounds, substantially as described.

706,120. ENGINE. SIDNEY H. SHORT, London, England. Filed Nov. 15, 1901. Serial No. 82,465. (No model.)



Claim.—1. In an engine, a water-jacketed crank-casing adapted to contain a body of oil, a non-water-jacketed cylinder, and a thermal insulation between said cylinder and said crank-casing.

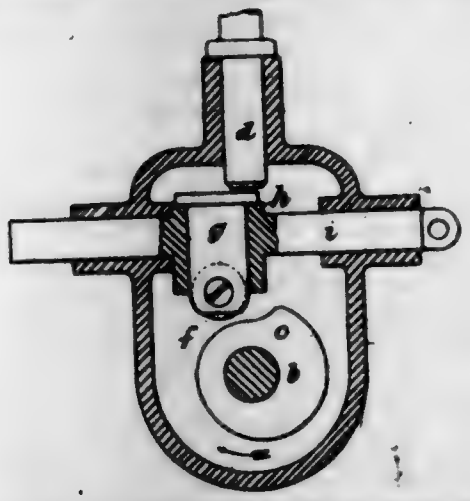
2. In an engine, a water-jacketed crank-casing, a cylinder insulated therefrom and covered with a non-conducting substance, said crank-casing being adapted to hold a considerable body of oil, a water-supply, means for conducting cooling-water from said water-supply through said water-jacket.

3. A steam-engine having a lagged steam-cylinder, an inclosed crank-chamber insulated therefrom, said crank-chamber adapted to contain a body of oil, a water-jacket about said crank-chamber, and a water-circulating system for said water-jacket leading to a boiler-supply.

4. A high-pressure steam-engine having a steam-cylinder, an inclosed crank-chamber adapted to contain a considerable body of oil in such a position that the movement of the engine parts shall splash oil contained therein upon the parts, a water-jacket about the said crank-chamber, and a water-circulating system for said water-jacket adapted to prevent overheating of oil in said crank-chamber.

5. A high-pressure steam-engine having a steam-cylinder, an inclosed crank-chamber adapted to contain a considerable body of oil in such a position that the movement of the engine parts shall splash oil contained therein upon the parts, a water-jacket about the said crank-chamber, and a water-circulating system for said water-jacket adapted to prevent overheating of oil in said crank-chamber, the said water-circulating system leading to a boiler-supply.

706,121. IGNITION-GEAR FOR INTERNAL-COMBUSTION ENGINES. FREDERICK R. SIMMS, Bermondsey, England, and ROBERT BOSCH, Stuttgart, Germany. Filed Sept. 20, 1901. Serial No. 75,863. (No model.)



Claim.—1. The combination with igniting devices provided with a movable member, of an igniter-operating cam, a slide, a push-piece carried by said slide and movable with respect thereto, said push-piece being interposed between the said cam and said movable member of the igniting devices, substantially as described.

2. The combination with the igniting devices provided with a movable member, of an igniter-operating cam, a slide adapted to be adjusted transversely with respect to the shaft of said cam, and provided with a socket, a push-piece movably engaging said socket and having a part to engage said movable member, and a part to engage said cam, substantially as described.

706,122. BRACKET. THEODORE SMITH, Chicago, Ill. Filed Nov 6, 1901. Serial No. 81,296. (No model.)

Claim.—1. The combination in a bracket, of an arm, adapted to be supported upon the wall and to swing in a horizontal plane, a block pivoted upon the extremity of said arm, likewise adapted to swing in a horizontal plane, a second arm, composed of two parallel rods connected to said block and adapted to swing in a vertical plane, said arm supporting, at its extremity, a second block, adapted to serve as a supporting device, with a clamp adapted to fix the position of said parallel-bar arm in any desired position; substantially as described.

2. The combination in a bracket of an arm, adapted to be supported upon the wall and to swing in a horizontal plane, a block pivoted upon the extremity of said arm, likewise adapted to swing in a horizontal plane, a second arm, composed of two parallel rods connected to said block and adapted to swing in a vertical plane, said arm supporting, at its extremity, a second block, adapted to serve as a supporting device, with a clamp embracing said parallel arms and adapted to fix their relative positions, thereby fastening the parallel-bar arm in any desired position; substantially as described.

3. The combination in a bracket, of an arm adapted to be supported upon the wall and to swing in a horizontal plane, a block pivoted upon the extremity of said arm, likewise adapted to swing in a horizontal plane, a second arm composed of two parallel rods connected to said block and adapted to swing in a vertical plane, said arm supporting, at its extremity, a second block, adapted to serve as a supporting device, with a clamp consisting of two portions, B', B^2, connected with a set-screw, embracing said parallel bars, one of said portions being provided with a rib, b', adapted to engage a notch, b^2, of one of said parallel arms, said clamp being adapted to be tightened by movement of said set-screw upon the other part of the arm, thereby fixing the position of the arm as desired; substantially as described.

4. The combination, in a bracket, having two arms suitably pivoted together, one of which contains two parallel rods, a', a^2, for controlling the movement thereof in one plane, of a limiting device for the joint, consisting substantially of two plates, provided with radial extensions adapted to be held in place upon one of the arms of said bracket, and a projecting plate upon the other arm, said radial extensions being adapted to engage said spline to limit the movement of the arm, with a clamp, B, adapted to hold firmly the bars, a', a^2, against relative longitudinal movement; substantially as described.

5. The combination, in a bracket, with a suitably-pivoted arm having a grooved end, a second arm containing two suitably-pivoted parallel

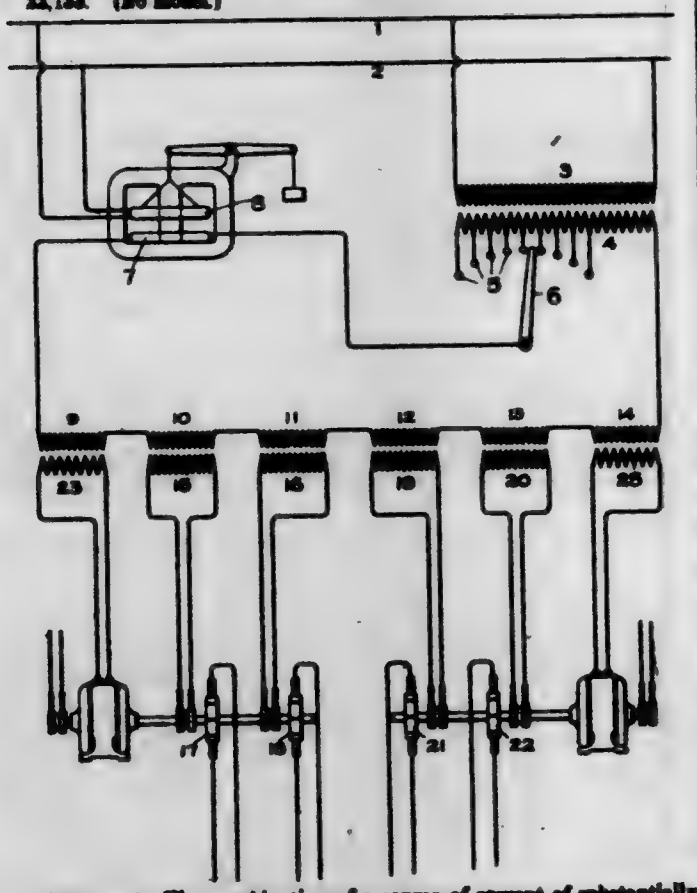
rods, pivoted upon the upturned end of said first arm, a device for limiting the horizontal movement of said second arm, consisting substantially of a plate, E^2, seated in said groove, a second plate supported on said second-named arm, and the plates, E', E^3, provided with radial extensions adapted to strike the plate, E', and held against radial movement upon said upturned end, of a clamp composed of two parts, E', E^3, adapted to hold the parallel rods of said second-named arm against relative longitudinal movement; substantially as described.

6. In a bracket, the combination with a suitable support, of a swinging arm pivoted therein and a device for limiting the movement of said arm comprising substantially two plates formed with radial extensions and with notches, a plate upon the support seated in notches in said plates to prevent rotation of said plates with respect to the support and a stop-plate upon the arm adapted to strike said radial extensions in the movement of said arm upon the support; substantially as described.

7. In the bracket, the combination with a support, of an arm journaled thereupon, containing two blocks and a pair of parallel rods pivoted upon said blocks and a device for limiting the movement of said arm upon the support comprising substantially two perforated plates seated upon said support and having radial extensions, and notches extending from said perforations, a plate seated in said support and engaging either of the notches in the plates, a second plate seated in said block and adapted to engage said radial extensions in the movement of the arm relative to said support; substantially as described.

8. In a bracket, the combination with a grooved vertical support, an arm pivoted thereupon and comprising substantially a split block seated upon the upturned end, a second block, a pair of parallel arms pivoted to both blocks and a set-screw adapted to clamp the block upon the support, of a device for limiting the swinging movement of said arm upon the support, comprising substantially two notched plates provided with radial extensions seated upon the support, a plate seated in the groove in the support and in the notches of the plates and a second plate secured in the block and adapted to strike the radial extensions, to limit the movement of the arm upon the support; substantially as described.

706,123. SYSTEM OF ELECTRICAL DISTRIBUTION. CHARLES P. STEINMETZ, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed June 30, 1900. Serial No. 22,123. (No model.)



Claim.—1. The combination of a source of current of substantially constant value, a plurality of rectifiers, and means for supplying said rectifiers with current from said source.

2. The combination of a source of current of substantially constant value, a plurality of rectifiers, and means for deriving current from said source inductively and supplying it to said rectifiers.

3. The combination of a source of constant current, a synchronous motor, a rectifying-commutator driven thereby, and means for starting and supplying both the synchronous motor and the rectifying-commutator with current derived from said source.

4. The combination of a constant-current circuit carrying alternating current, a plurality of transformers having windings in series therewith, and rectifying-commutators fed from said transformers.

5. The combination of a constant-current circuit, and a plurality of rectifying-commutators supplied with current thereby.

6. The combination of a transformer having a divided secondary, a constant-current-regulating device in series with said secondary, and a consumption-circuit fed by said secondary and regulating device.

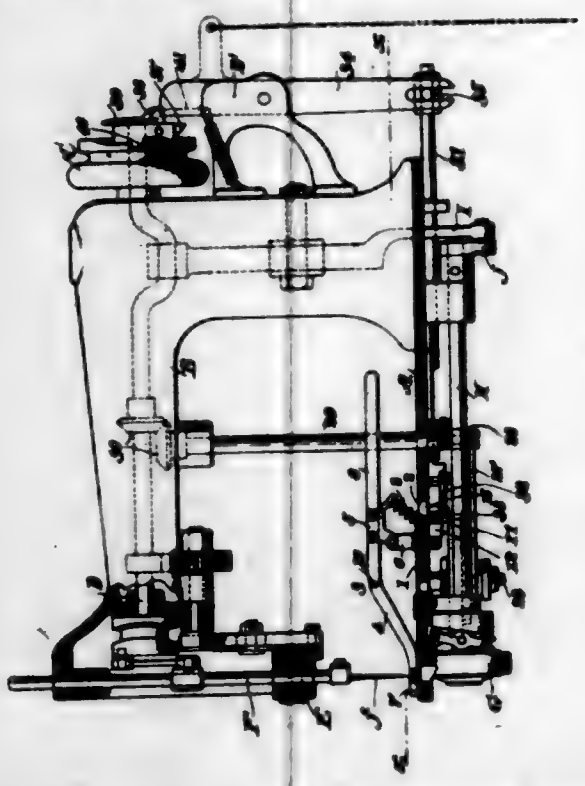
7. The combination of a plurality of sources of variable alternating electromotive force in series, and rectifying devices fed from said sources.

8. The combination of a constant-current circuit, a plurality of transformers having windings in series with said circuit, and rectifying-commutators fed from other windings on said transformers.

9. The combination of a constant-current circuit, means for deriving other constant-current circuits therefrom, and means for rectifying current flowing in the constant-current circuits last mentioned.

10. The combination of constant-potential mains, a transformer having its primary connected across said mains, a constant-current circuit including the secondary of said transformer, and means for varying the number of active turns of said secondary.

706,124. BUTTON-SEWING MACHINE. BENJAMIN T. STERN, Philadelphia, Pa., assignor to Clarence R. Mullen, Philadelphia, Pa. Filed July 17, 1900. Serial No. 23,916. (No model.)



Claim.—1. In a button-sewing machine, the combination with stitch-forming mechanism and a button-holder, of means for imparting a vibratory movement to the needle-bar, and means comprising a cam to impart a vibratory movement to the button-holder in a plane at substantially a right angle to the plane of vibration of the needle-bar and simultaneously therewith and to suspend the motions of said button-holder during the vibration of the needle-bar.

2. In a button-sewing machine, the combination with stitch-forming mechanism and a button-holder, a slide-plate which is secured to the button-holder, and a cam for positively actuating said plate to impart to said holder a vibratory movement in a direction at substantially a right angle to the plane of movement of the needle-bar and simultaneously with the vibratory movement of the needle-bar and for suspending the motions of said button-holder during the vibration of the needle-bar.

3. In a button-sewing machine, the combination with stitch-forming mechanism and a button-holder, of means for imparting a vibratory movement to the needle-bar, means comprising a cam to impart a vibratory movement to the button-holder in a plane at substantially a right angle to the plane of vibration of the needle-bar and simultaneously therewith and to suspend the motions of said button-holder during the vibration of the needle-bar, and stop-motion devices to arrest both the needle-bar and button-holder after a given number of reciprocations.

4. In a button-sewing machine, the combination with stitch-forming mechanism and a button-holder, of means for imparting a vibratory movement to the needle-bar, means comprising a cam to impart a vibratory movement to the button-holder in a plane at substantially a right angle to the plane of vibration of the needle-bar and simultaneously therewith

and to suspend the motions of said button-holder during the vibration of the needle-bar, stop-motion devices to arrest both the needle-bar and button-holder after a given number of reciprocations, means to hold said stop-motion devices out of action, and means to automatically operate said means for holding the stop-motion devices out of action after a given number of reciprocations of the needle-bar and button-holder.

5. In a button-sewing machine, the combination with stitch-forming mechanism and a button-holder, of means for imparting a vibratory movement to the needle-bar, means comprising a cam to impart a vibratory movement to the button-holder in a plane at substantially a right angle to the plane of vibration of the needle-bar and simultaneously therewith and to suspend the motions of said button-holder during the vibration of the needle-bar, power-transmitting connections between said means for vibrating the needle-bar and means for vibrating the button-holder, and a stop-motion for controlling said power-transmitting connections controlled by the means for vibrating the needle-bar.

6. In a button-sewing machine, the combination with a vibrating needle, base-frame, and a driving-shaft carried by the overhanging arm, to vibrate said needle, of a reciprocating button-carrier movable transversely on said base-frame to the line of vibration of the needle, a cam device to reciprocate said carrier provided with means to stop said reciprocation during a vibration of the needle, connections between said cam device and button-carrier located wholly below said base-frame, and power-transmitting connections between said cam device and the driving-shaft in the overhanging arm, embracing a vertical shaft 29 extending between the base-frame and the overhanging arm.

7. In a button-sewing machine, the combination with a vibrating needle, of a reciprocating button-carrier movable transversely to the line of vibration of the needle of a cam device for reciprocating said carrier provided with means for stopping the reciprocation of said carrier during a vibration of the needle, a bell-crank lever 11 operatively connected with said carrier, a lever pivoted to said bell-crank lever, power-transmitting connections between said second lever and the cam device, and an adjustable fulcrum for said second lever whereby the throw of the bell-crank lever and the extent of reciprocation imparted to the carrier may be adjusted.

8. In a button-sewing machine, the combination with a vibrating needle, of a reciprocating button-carrier movable transversely to the line of vibration of the needle of a cam device for reciprocating said carrier provided with means for interrupting the reciprocation of said carrier during a vibration of the needle, the bell-crank lever 11 operatively connected with the carrier, the slide 20 operated by the cam device, and the lever 17 between the slide 20 and the bell-crank lever 11.

9. In a button-sewing machine, the combination with a vibrating needle, of a reciprocating button-carrier movable transversely to the line of vibration of the needle of a cam device for reciprocating said carrier provided with means for interrupting the reciprocation of said carrier during a vibration of the needle, the bell-crank lever 11 operatively connected with the carrier, the slide 20 operated by the cam device, and the lever 17 between the slide 20 and the bell-crank lever 11, said lever 17 having an adjustable fulcrum 18, substantially as and for the purposes described.

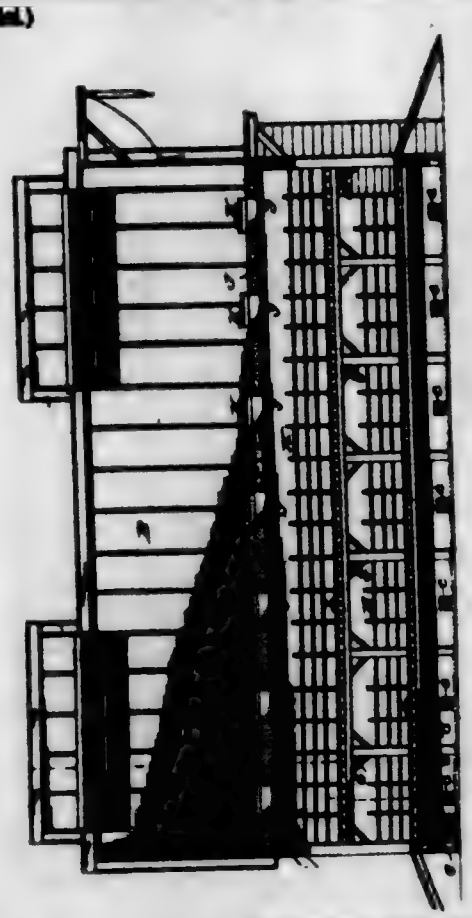
10. In a button-sewing machine, the combination with a vibrating needle, of a reciprocating button-carrier movable transversely to the line of vibration of the needle of a cam device for reciprocating said carrier provided with means for interrupting the reciprocation of said carrier during a vibration of the needle, the bell-crank lever 11 operatively connected with the carrier, the slide 20 operated by the cam device, and the lever 17 between the slide 20 and the bell-crank lever 11, said lever 17 having a fulcrum 18 carried by an adjustable rod 19 substantially as and for the purposes described.

11. In a button-sewing machine, the combination with a vibrating needle and means to vibrate it, of a reciprocating button-carrier movable transversely to the line of vibration of the needle, and a cam device independent of the means for vibrating the needle adapted to impart a series of reciprocations to said carrier and provided with a portion *f*, adapted to temporarily interrupt the reciprocation of the carrier during the vibration of the needle.

12. In a button-sewing machine, the combination with a vibrating needle and means to vibrate it, of a reciprocating button-carrier movable transversely to the line of vibration of the needle, and a cam device independent of the means for vibrating the needle adapted to impart a series of reciprocations to said carrier and provided with a portion *f*, adapted to temporarily interrupt the reciprocation of the carrier during the vibration of the needle, a stop-motion adapted to arrest both the needle and button-carrier after a given number of reciprocations, and means controlled by the cam device to control said stop-motion.

13. In a button-sewing machine, the combination with stitch-forming mechanism, of a reciprocating button-carrier, a cam device adapted to impart a series of reciprocations to said carrier, provided with a portion *f* adapted to temporarily interrupt said reciprocations, a stop-motion adapted to arrest the machine after a given number of reciprocations, a rod 31 operatively connected with said stop-motion, and provided with a dog 32, a fixed lug 33 adapted to be engaged by said dog to retain the rod 31 and hold the stop-motion out of action, and a lug 45 carried by the cam device adapted to disengage said dog and throw said stop-motion into action.

706,125. PRESERVING AND STORING BUILDING. JOHN H. STRAUS, San Antonio, Tex. Filed May 16, 1902. Serial No. 107,586. (No model.)



Claim.—A preserving and storing building, air-inlets at or near the bottom thereof, shelves located on a plane above said inlets for supplying with charcoal or other like ingredients, suitable grates located over and above the shelves, removable trays for receiving fruit or other product located over and above the grates, a central driveway located between the grates, walkways extending upon each side of the building, removable trays located above the walkways, and a plurality of valves at the top of the building for regulating the escape of the air therefrom, substantially as and for the purpose set forth.

706,126. ELECTRIC CONTROLLING APPARATUS FOR ELEVATORS. ANDREW SMITH, Yonkers, N. Y., assignor to Otis Elevator Company, East Orange, N. J., a Corporation of New Jersey. Filed Jan. 31, 1902. Serial No. 92,093. (No model.)

Claim.—1. The combination with a motor and its supply-line, of a controlling-circuit of lower potential than the line derived from a shunt to said line, substantially as described.

2. The combination with a motor and its supply-line, of a controlling-circuit of lower potential than the line derived from a shunt to said line, and means for varying the potential of said controlling-circuit, substantially as described.

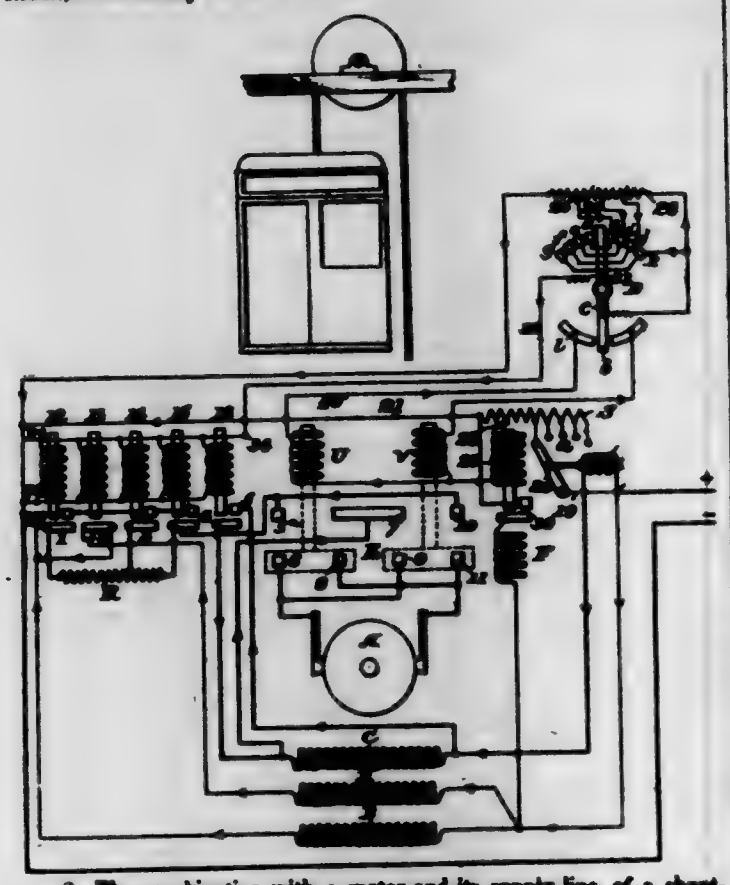
3. The combination with a motor and its supply-line, of a shunt to the line, a controlling-circuit derived therefrom, and means for varying the electric potential of said controlling-circuit in accordance with the current on the line, substantially as described.

4. The combination with a motor and its supply-line, of a controlling-circuit of lower potential than the line deriving its energy from said supply-line, and means for varying the power of said controlling-circuit for doing work without varying that of the line, substantially as described.

5. The combination with an electric motor and its supply-line, of a controlling-circuit of lower potential than the line deriving its energy from said supply-line, and means for varying the electric potential of said controlling-circuit without varying that of the line, substantially as described.

6. The combination with a motor and its supply-line, of a controlling-circuit for the motor deriving its energy from said line, and means for increasing the electric potential of the controlling-circuit without increasing that of the line, substantially as described.

7. The combination with a motor and its supply-line, of a controlling-circuit deriving its energy from said line, and means for varying at will the difference of potential between the terminals of said controlling-circuit, substantially as described.



8. The combination with a motor and its supply-line, of a shunt-circuit across the line, a controlling-circuit derived from said shunt-circuit, and means for varying the difference of potential between the terminals of said controlling-circuit, substantially as described.

9. The combination with a motor and its supply-line, of a shunt-circuit across the line, a controlling-circuit derived from said shunt-circuit, and means for varying the difference of potential between the terminals of said controlling-circuit in accordance with variations of the current on the line, substantially as described.

10. The combination with a motor and its supply-line, of a controlling-circuit derived from said line, means for varying the electric potential in said controlling-circuit, and means for regulating the variations of said potential, substantially as described.

11. The combination with a motor and its supply-line, of a controlling-circuit derived from said line, means for varying the electric potential in said controlling-circuit, and means for regulating the variations of said potential in accordance with the current on the line, substantially as described.

12. The combination with a motor and its supply-line, of a shunt across the line, a circuit derived therefrom, means for varying the potential in said circuit, and means for regulating the variations of said potential, substantially as described.

13. The combination with a motor and its supply-line, of a shunt-circuit across the line, a controlling-circuit derived therefrom, and means for varying the electric potential of said controlling-circuit, substantially as described.

14. The combination with a motor and its supply-line, of a shunt-circuit across the line, a controlling-circuit derived therefrom, and means for varying the electric potential of said controlling-circuit without varying that of the line, substantially as described.

15. The combination with a motor and its supply-line, of a shunt-circuit across the line, a controlling-circuit derived therefrom, and means for maintaining a constant electric potential in said controlling-circuit, substantially as described.

16. The combination with a motor and its supply-line, of a shunt-circuit across the line, a controlling-circuit derived from said shunt-circuit, another controlling-circuit derived from said controlling-circuit, and means for varying the electric potential of said controlling-circuits, substantially as described.

17. The combination with a motor and its supply-line, of a shunt-circuit across the line, a controlling-circuit derived from said shunt-circuit, another controlling-circuit derived from said controlling-circuit, and means for varying the electric potential of each of said controlling-circuits, substantially as described.

18. The combination with a motor and its supply-line, of a shunt across the line including resistance, a controlling-circuit shunting a portion of said resistance and itself including resistance, and another controlling-circuit shunting the resistance in said controlling-circuit, substantially as described.

19. The combination with a motor and its supply-line, of a shunt across the line including variable resistance, a controlling-circuit shunting a portion of said resistance and itself including resistance, and another controlling-circuit shunting the resistance in said controlling-circuit, substantially as described.

20. The combination with a motor and its supply-line, of a shunt across the line including resistance, a controlling-circuit shunting a portion of said resistance and itself including resistance, another controlling-circuit in shunt to said controlling-circuit, and means for connecting said other circuit to different points on the resistance in said controlling-circuit, substantially as described.

21. The combination with a motor and its supply-line, of a shunt across the line, a circuit derived from said shunt and including resistance, a controlling-circuit connected in shunt to said derived circuit, and means for connecting said controlling-circuit to different points on said resistance, substantially as described.

22. The combination with a motor and its supply-line, of a shunt across the line, a circuit derived from said shunt, a controlling-circuit in shunt to said derived circuit, and means for connecting said controlling-circuit to different points on said derived circuit, substantially as described.

23. The combination with a motor and its supply-line, of a shunt across the line including a resistance, means for varying said resistance in accordance with the current on the line, a circuit derived from said shunt and shunting a portion of said variable resistance, a controlling-circuit in shunt to said derived circuit, and means for connecting said controlling-circuit to different points on said derived circuit, substantially as described.

24. The combination with a motor and the main line, of a shunt across the line including a variable resistance, means for varying said resistance in accordance with variations of current on the line, a circuit derived from said shunt and shunted across said variable resistance and itself including a resistance, a controlling-circuit in shunt to said derived circuit, and means for connecting said controlling-circuit to different points on the resistance in said derived circuit, substantially as described.

25. In an apparatus for controlling elevators, the combination with a motor and its supply-line, of a shunt across the line, a circuit derived therefrom including means for operating a motor-reversing switch, and another circuit in shunt to said derived circuit and including means for controlling the starting and stopping of the motor, substantially as described.

26. In an apparatus for controlling elevators, the combination with a motor and its supply-line, of a shunt across the line, a circuit derived therefrom including means for operating a motor-reversing switch, another circuit in shunt to said derived circuit and including means for controlling the starting and stopping of the motor, and means for varying the potential in said other circuit in shunt to said derived circuit, substantially as described.

27. In an apparatus for controlling elevators, the combination with a motor and its supply-line, of a shunt across the line, a circuit derived therefrom including means for operating a motor-reversing switch, another circuit in shunt to said derived circuit and including means for controlling the starting and stopping of the motor, and means for connecting said other circuit to different points on said derived circuit, substantially as described.

28. The combination with a motor and its supply-line, of a shunt across the line, a circuit derived from said shunt, a controlling-circuit in shunt to said derived circuit and including means for controlling armature resistance, means for connecting said controlling-circuit to different points on said derived circuit, and means for preventing the cutting out of said armature resistance too quickly on starting the motor with an excess of current on the line, substantially as described.

29. The combination with a motor and its supply-line, of a shunt across the line, a circuit derived from said shunt, a controlling-circuit in shunt to said derived circuit, means for varying the electric potential of said controlling-circuit, and means for regulating the variations of potential of said controlling-circuit, substantially as described.

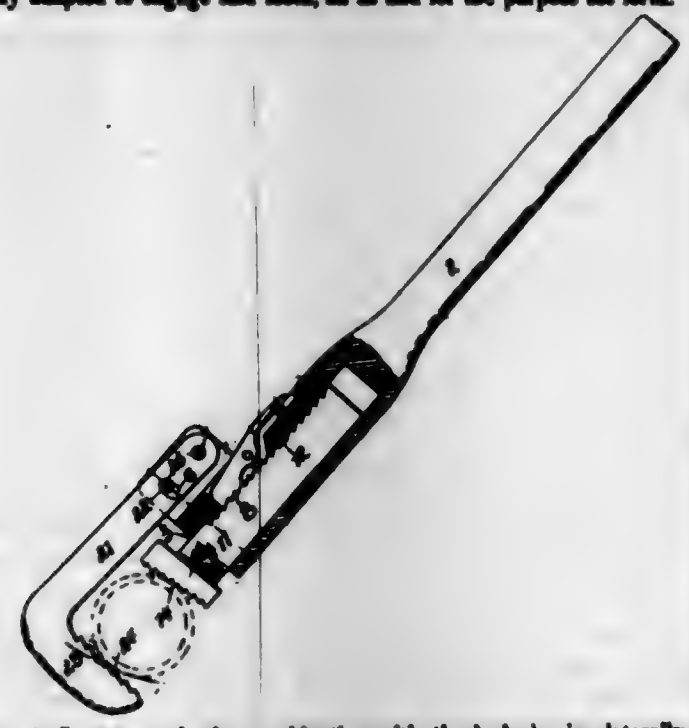
30. The combination with a motor, and its armature-circuit, of a motor-controlling circuit, and an electromagnet for varying the electric potential of said controlling-circuit by means of the current in the armature-circuit, substantially as described.

31. The combination with a motor, and its main circuit, of a controlling-circuit in shunt to said main circuit, and means operated by the current in the main circuit for varying the electric potential of the shunt-circuit, substantially as described.

706,127. WRENCH. PETER TABOLL, Delray, Mich. Filed May 17, 1902. Serial No. 107,730. (No model.)

Claim.—1. In a wrench, the combination with the body having lat-

erally-projecting wings pierced with two pairs of holes, an L-shaped outer jaw having two holes through its stem adapted to register with those in the wings, and two bolts removably seated in said holes; of an inner jaw having a stem entering the body and provided with teeth, a head on this jaw whose face is inclined downwardly and inwardly, and a catch on the body adapted to engage said teeth, all as and for the purpose set forth.



2. In a wrench, the combination with the body having laterally-projecting wings pierced with two pairs of holes of which the forward pair is oval, an L-shaped outer jaw having two holes through its stem adapted to register with those in the wings, and two bolts removably seated in said holes; of an inner jaw having a stem entering the body and adjustable longitudinally therein, a head on this jaw whose forward face stands in a plane slightly oblique to an upright line at right angles to its stem, and means for holding this stem in adjusted position.

3. In a wrench, the combination with the body having laterally-projecting wings pierced with two pairs of holes, an L-shaped outer jaw having two holes through its stem adapted to register with those in the wings, and two bolts removably seated in said holes; of an inner jaw having a stem entering the body and provided with teeth, and a catch on the body adapted to engage said teeth, all as and for the purpose set forth.

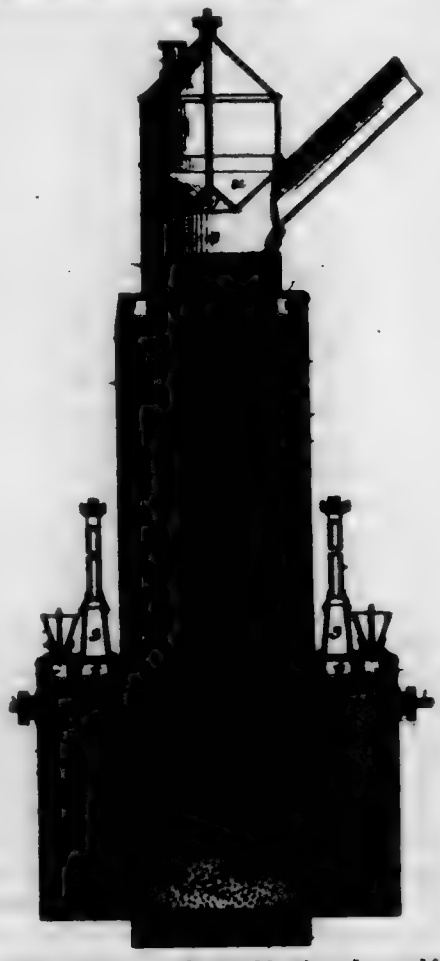
4. In a wrench, the combination with the body having laterally-projecting wings pierced with two pairs of holes of which the forward pair is oval, an L-shaped outer jaw having two holes through its stem adapted to register with those in the wings, and two bolts removably seated in said holes; of an inner jaw having a stem entering the body and adjustable longitudinally therein, and means for holding this stem in adjusted position.

706,128. ELECTRIC FURNACE. EDWARD R. TAYLOR, Penn Yan, N. Y. Filed Apr. 4, 1901. Renewed Jan. 2, 1902. Serial No. 88,042. (No model.)

Claim.—1. An electric furnace having, in combination, a working chamber, means for continuously supplying the same with material for a given reaction or reduction, conduits constructed of conductive material and arranged to discharge into the working chamber by gravity, means for feeding into and through said conduits fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, and means for connecting said conduits with a suitable generator of electricity.

2. In an electric furnace, the combination of a working chamber, means for continuously supplying the same with material for a given reaction or reduction, conduits constructed of conductive material and arranged to discharge into the working chamber by gravity, means for feeding into and through said conduits fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, means for connecting said conduits to a suitable generator of electricity, passages opening into the working chamber in front of said conduits and above their outlets, and means for feeding either conductive or non-conductive material through said passages at will.

3. In an electric furnace, the combination of a working chamber, means for continuously supplying the same with material for a given reaction or reduction, conduits constructed of conductive material and arranged to discharge into the working chamber by gravity, means for feeding into and through said conduits fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, means for connecting said conduits with a suitable generator of electricity, a dome provided with means for the removal of gaseous material from the working chamber, and a suitable tap-hole at the bottom of the working chamber for the removal of fused material.



4. In an electric furnace, the combination of a working chamber, an inlet into the working chamber for material for a given reaction or reduction, inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, conduits constructed of conductive material and arranged to receive said fragmentary conductive material and to discharge the same into the working chamber by gravity, and means for connecting said conduits with a suitable generator of electricity.

5. In an electric furnace, the combination of a working chamber, an inlet into the working chamber for material for a given reaction or reduction, inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, conduits constructed of metal lined with carbon brick and arranged to receive said fragmentary conductive material and to discharge the same into the working chamber by gravity, and means for connecting said conduits with a suitable generator of electricity.

6. In an electric furnace, the combination of a working chamber, an inlet into the working chamber for material for a given reaction or reduction, inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, conduits, in communication with the inlets last named, arranged for the descent of said fragmentary conductive material therethrough by gravity, and constructed with conductive back walls having inclined lower portions to retard and direct the flow of said fragmentary conductive material, and means for connecting said conduits with a suitable generator of electricity.

7. In an electric furnace, the combination of a working chamber, an inlet into the working chamber for material for a given reaction or reduction, inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, downwardly-extending passages, in communication with the inlets last named, and conduits constructed of conductive material leading from said passages, adapted to contain together a supply of such fragmentary conductive material, and arranged to discharge the same into the working chamber by gravity, and means for connecting said conduits with a suitable generator of electricity.

8. In an electric furnace, the combination of a working chamber, an inlet into the working chamber for material for a given reaction or reduction, inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, conduits constructed of conductive material and arranged at the sides of the furnace for the passage therethrough of said fragmentary conductive material into the working chamber by gravity, means for connecting said conduits with a suitable generator of electricity, and protective walls of non-conductive material between said conduits respectively and the middle of the furnace.

9. In an electric furnace, the combination of a working chamber, an

inlet into the working chamber for material for a given reaction or reduction, inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, conduits, in communication at their respective ends with the inlets last named and with the working chamber, each having back and side walls of metal provided with a refractory conductive lining and arranged at the sides of the furnace, means for connecting the metallic walls of the conduits with a suitable generator of electricity, and protective walls of non-conductive material interposed between the open fronts of the conduits respectively and the middle of the furnace.

10. In an electric furnace, the combination of a working chamber, an inlet into the working chamber for material for a given reaction or reduction, inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, trough-shaped conduits, constructed of conductive material, in communication with the inlets last named and with the working chamber at their respective ends, and arranged at the sides of the furnace with their open sides toward its middle, means for connecting said conduits with a suitable generator of electricity, and protective walls of non-conductive material bridging said open sides of the respective conduits.

11. In an electric furnace, the combination of a working chamber, an inlet into the working chamber for material for a given reaction or reduction, inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, conduits, constructed of conductive material, arranged at the sides of the furnace and adapted for the passage therethrough into the working chamber of said fragmentary conductive material, means for connecting said conduits with a suitable generator of electricity, and inlets, adjacent to said conduits, adapted for the admission of material between said conduits respectively and the middle of the furnace.

12. In an electric furnace, the combination of a working chamber adapted for the location of a heat zone within its lower portion, an inlet into the working chamber for material for a given reaction or reduction, inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, conduits, constructed of conductive material, extending inwardly downward toward the bottom of the furnace, and adapted for the descent of the fragmentary conductive material therethrough into the lower portion of the working chamber by gravity, and means for connecting said conduits with a suitable generator of electricity.

13. In an electric furnace, the combination of a working chamber adapted for the location of its heat zone at bottom, inlets for fusible material for a given reaction or reduction near the bottom of the working chamber, higher inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, conduits for such electrodes discharging downwardly toward the bottom of the furnace and having conductive walls, and means for connecting said conduits with a suitable generator of electricity.

14. In an electric furnace, the combination of a working chamber adapted for the location of its heat zone at bottom, an inlet for material for a given reaction or reduction, inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, conduits for such electrodes constructed of conductive material and arranged to direct the electrodes downwardly into the bottom of the working chamber and toward each other, means for connecting said conduits with a suitable generator of electricity, and an outlet at the bottom of the working chamber for a liquid product of the furnace.

15. In an electric furnace for making chemicals, the combination of a working chamber adapted for the location of its heat zone at bottom, spaces surrounding said working chamber and communicating therewith through passages in its lower walls at a considerable height above its bottom, means for feeding fusible material into said spaces on its way to the working chamber, and means for passing a suitable electric current through the charge.

16. In an electric furnace for making chemicals, the combination of a working chamber adapted for the location of its heat zone at bottom, spaces surrounding said working chamber and communicating therewith through passages in its lower walls near its bottom and at a considerable height above the same, respectively, means for feeding fusible material into said spaces on its way to the working chamber, and means for passing a suitable electric current through the charge.

17. In an electric furnace for making bisulfid of carbon, the combination of a working chamber adapted for the location of its heat zone at bottom, spaces surrounding the upper portion of the working chamber within its walls and communicating with the working chamber through passages in its lower walls at a considerable height above its bottom, means for feeding crushed sulfur into said spaces, and means for passing a suitable electric current through the charge.

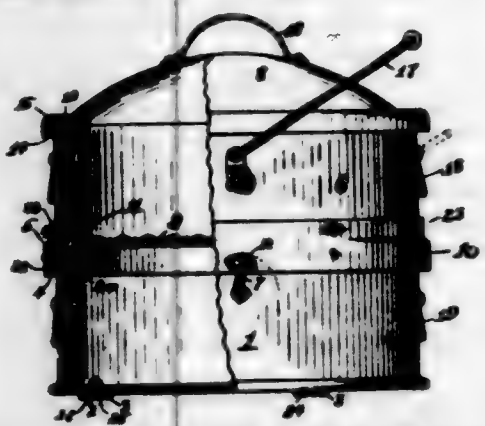
18. In an electric furnace for making bisulfid of carbon, the combination of a working chamber adapted for the location of its heat zone at bottom, spaces surrounding the working chamber within its walls and having their bottoms at different heights, passages connecting the respective spaces with said working chamber in a plane near its bottom and at a considerable height above said plane, means for feeding crushed sulfur into said spaces, and means for passing a suitable electric current through the charge.

19. In an electric furnace for making bisulfid of carbon, the combination of a working chamber adapted for the location of its heat zone at bottom, inlets into said working chamber at top and in a plane near its bottom, adapted respectively for the introduction of carbon and sulfur, inlets at an intermediate height for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, conduits constructed of conductive material and arranged for the passage of said fragmentary conductive material therethrough into the bottom of the working chamber, and means for connecting said conduits with a suitable generator of electricity.

20. In an electric furnace for making bisulfid of carbon, the combination of a working chamber adapted for the location of its heat zone at bottom, inlets into said working chamber at top and through passages in its side walls at different heights, adapted respectively for the introduction of the carbon and sulfur, inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, conduits constructed of conductive material and arranged for the passage of said fragmentary conductive material therethrough into the bottom of the working chamber, and means for connecting said conduits with a suitable generator of electricity.

21. In an electric furnace for making bisulfid of carbon, the combination of a working chamber adapted for the location of its heat zone at bottom, inlets into said working chamber at top and through passages in its side walls adapted respectively for the introduction of the carbon and sulfur, inlets for fragmentary conductive material adapted to constitute self-renewing electrodes in the working furnace, conduits constructed of conductive material and arranged for the passage of said fragmentary conductive material therethrough into the bottom of the working chamber, means for connecting said conduits with a suitable generator of electricity, and an outlet at the bottom of the working chamber for the residue from the carbon and sulfur in fused condition.

706,129. ASH-SIFTER. ISAIAH H. TAYLOR, Baltimore, Md., assignor of one-half to Frank R. Hooper, Baltimore, Md. Filed Feb. 20, 1901. Serial No. 48,040. (No model.)



Claim.—1. In an ash-sifter, the combination with the receptacle 6, of the base or ring, 10, having projecting flanges, 20, 21, forming an annular groove, 22, the antifriction-bearings, 5, secured in said groove, the screen, 9, secured to the base or ring, and receptacle, 1, provided with the guideway, 4, over which the said groove fits and on which said bearings rest.

2. In an ash-sifter, the combination of the receptacle 1; the receptacle, 6; the screen, 9; the base or ring, 10, having flanges, 20, and 21 resting upon the upper edge of the receptacle, 1; and the hook-headed bolts, 11, to draw the screen taut and hold jointly the base 10 and screen, 9, to the receptacle, 6.

3. In an ash-sifter, the combination with the receptacle 6, of the base or ring, 10, having projecting flanges 20, 21, forming an annular groove, 22, the antifriction-bearings, 5, secured in the groove 22, the screen, 9, secured to the base or ring, and receptacle, 1, over which the said groove fits.

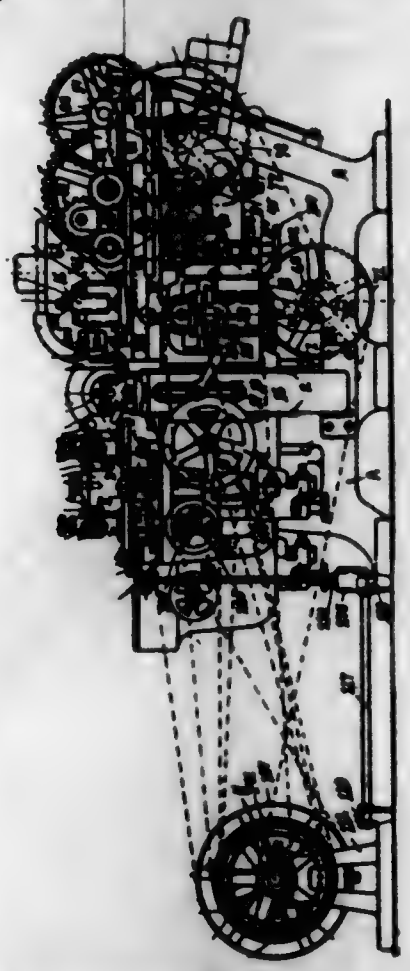
4. In an ash-sifter, the combination with the receptacle 6, of the base or ring, 10, having projecting flanges 20, 21 and 23; the removable screen, 9; hook-headed bolts, 11, having one end engaging the screen, 9, and the opposite end passing through the receptacle, 6, and the flange 23 of the base or ring, 10; and the receptacle, 1, over which the flanges 20 and 21 of the base 10 fit.

5. In an ash-sifter, the combination with the receptacle 6 of a base

or ring, 10, having projecting flanges 20, 21 and 23; antifriction-bearings, 5, between the flanges 20 and 21; the removable screen, 9, held in position by the hook-headed bolts, 11, engaging the screen and passing through the receptacle, 6, and the flange, 23 of the base or ring, 10; and the receptacle, 1, over the upper edge of which flanges 20 and 21 project and on which the said bearings rest.

6. In an ash-sifter, the combination of the receptacle 1; the receptacle, 6, adapted to be received upon the receptacle 1; a base or ring secured to the lower end of the receptacle 6; a removable screen, 9, secured to the said base or ring; hook-headed bolts, 11, engaging the screen and holding jointly the screen and ring, or base, to the lower end of the receptacle, 6; and antifriction-rollers between the receptacles 1 and 6.

706,180. MOLDING-MACHINE. JOHN R. THOMAS, Cincinnati, Ohio, assignor to J. A. Fay & Egan Company, Cincinnati, Ohio, a Corporation of West Virginia. Filed May 20, 1901. Serial No. 60,413. (No model.)



Claim.—1. In a molding-machine, the combination of a lower cutter-head cutting first, an upper cutter-head cutting next, and side cutter-heads cutting thereafter, with a plurality of pairs of feeding-in rolls having their upper rolls driven down, and a counter-shaft for turning the cutter-heads located at the feed-out end of the machine, substantially as described.

2. In a molding-machine, the combination of a lower cutter-head cutting first, an upper cutter-head cutting next, and side cutter-heads cutting thereafter, with a counter-shaft for turning the cutter-heads located at the feed-out end of the machine, and an adjustable connection between the counter-shaft and the frame of the machine for sliding the counter-shaft with relation to the frame, substantially as described.

3. In a molding-machine, the combination of a frame, a lower cutter-head cutting in advance, an upper cutter-head cutting thereafter, and two side cutter-heads cutting after the lower and upper cutter-heads, with a plurality of pairs of feeding-in rolls having their upper rolls driven down, and a counter-shaft with a frame therefor at the feed-out end of the machine for turning the cutter-heads, a plurality of rods connecting the frame of the molding-machine with the counter-shaft frame, with means at the rods for adjusting the distance between the frames, substantially as described.

4. In a molding-machine, the combination of a main frame with an outer secondary frame therefor, a lower cutter-head mounted on the outer secondary frame, with a feeding-in table located on the outer secondary frame in advance of the lower cutter-head, and means for adjusting the feeding-in table with relation to the outer secondary frame, with the lower cutter-head cutting first, an upper cutter-head mounted in the frame cutting thereafter, and side cutter-heads cutting after the upper cutter-head, feeding-in rolls having the upper rolls driven down, and a counter-shaft located at the feeding-out end of the machine for turning the cutter-heads, substantially as described.

5. In a molding-machine, the combination of a main frame, an outer secondary frame therefor, a lower cutter-head mounted at the feeding-in end of the outer secondary frame, with a supplemental frame carrying a feeding-in table, with means between the feeding-in table and the outer secondary frame for adjusting the former with relation to the latter, with feed-roll mounted in the supplemental frame, means for adjusting the feed-roll in the supplemental frame and means for turning the feed-roll from the main frame, upper feed-rolls driven down, an upper cutter-head, and side cutter-heads, with a counter-shaft located at the feed-out end of the machine for turning the cutter-heads, substantially as described.

6. In a molding-machine, the combination of a side head, slide, with a rearward extension therefor, a chip-breaker, and a side gage adjustably secured to the rearward extension, with means for sidewise adjustment of the slide for simultaneously adjusting the side head, chip-breaker and side gage, substantially as described.

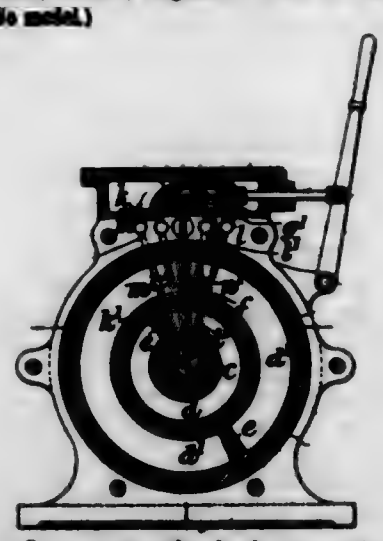
7. In a molding-machine, the combination of a side head, slide, forward extension therefor, a side head and a saddle therefor secured to the slide between the slide and the forward extension, with a removable spanner-plate secured to the inner edge of the slide and forward extension for supporting the stock when passing the side head, with means for adjusting the slide sidewise and thereby simultaneously adjusting the slide, forward extension, side head and spanner-plate, substantially as described.

8. In a molding-machine, the combination of a main frame, an outer secondary frame therefor, guideway between the main frame and the outer secondary frame, means for adjusting the outer secondary frame up and down on the main frame, a lower cutter-head mounted at the feed-in end of the outer secondary frame, a supplemental frame carrying a feed-in table in advance of the lower cutter-head mounted on the outer secondary frame, means for adjusting the supplemental frame and its table up and down upon the outer secondary frame, with side cutter-heads mounted on the outer secondary frame at its feed-out end, and a counter-shaft at the feed-out end of the machine for turning the cutter-heads, substantially as described.

9. In a molding-machine, the combination of a frame, a lower cutter-head, an upper cutter-head, and side cutter-heads, with a counter-shaft and frame therefor for turning the cutter-heads located at the feed-out end of the machine, with a plurality of rods connecting the frame of the molder with the frame of the counter-shaft, with means for adjusting the distance between the frames.

10. In an outside molding-machine, the combination of a lower cutter-head, an upper cutter-head, with side cutter-heads, and a counter-shaft for operating the cutter-heads located at the feed-out end of the machine for the uses and purposes described.

706,181. DISTRIBUTING-VALVE FOR STEAM-ENGINES. CHARLES TOOKFIELD, East Molesey, England, assignor of two-thirds to Dyson Weston, London, England. Filed Nov. 15, 1901. Serial No. 82,260. (No model.)



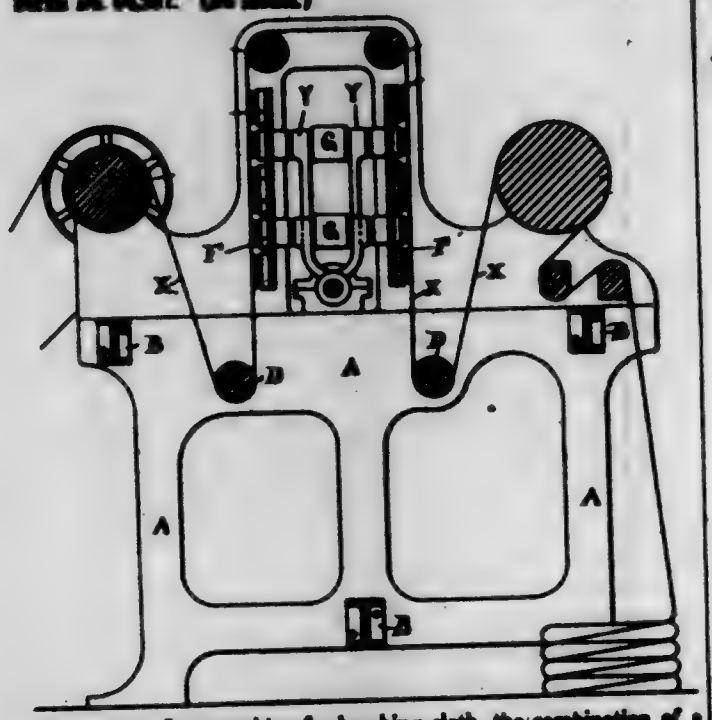
Claim.—1. In a steam-engine having more than one steam-cylinder or steam-space, a valve-casing having steam ports and passages communicating with each end of the said cylinders or steam-spaces and a slide-valve movable to different positions having passages therein, whereby two positions of the slide-valve will make cylinders or steam-spaces high-pressure engines in opposite directions and two other positions will make the cylinders or steam-spaces a compound engine in opposite directions, substantially as described.

2. The combination with a motor provided with a plurality of cylinders or steam-spaces, of a valve-chest provided with a main inlet and an exhaust-outlet, and with separate inlet and exhaust ports communicating with each of said cylinders or steam-spaces, a sliding valve in said

sheet, provided with a passage for connecting the exhaust-ports for one cylinder or steam-space with the inlet-ports of another cylinder or steam-space and a separate passage, for connecting the exhaust-port of the last cylinder or steam-space with the main exhaust, whereby two positions will make the cylinders or steam-spaces high-pressure engines moving in opposite directions and two other positions will make said cylinders or steam-spaces a compound engine moving in opposite directions, substantially as described.

3. The combination with a motor provided with a plurality of cylinders or steam-spaces, of a valve-sheet provided with a main inlet and an exhaust-outlet, and with separate inlet and exhaust ports communicating with each of said cylinders or steam-spaces, a sliding valve in said sheet provided with separate passages for independently connecting certain ports of the valve-casing whereby the motor may be adjusted as a high-pressure or compound motor, and reversed, in either adjustment, and means for moving said valve, substantially as described.

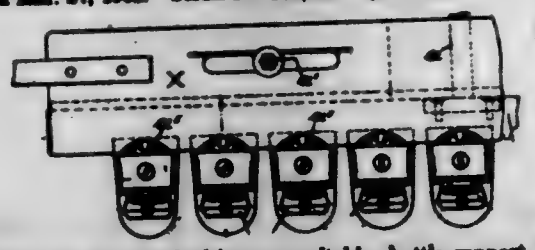
706,182. BRUSHING-MACHINE FOR CLOTH MANUFACTURE. James W. Voelker, Woonsocket, R. I. Filed June 12, 1901. Serial No. 64,367. (No model.)



Claim.—1. In a machine for brushing cloth, the combination of a series of disks, with brushes upon their faces, arranged side by side in two rows across the cloth to be brushed and with the brushes of one row placed to cover the spaces between those of the other row, means for causing the cloth to pass over the brushes, and means for rotating the disks.

2. In a machine for brushing cloth, a number of pairs of disks with brushes upon their faces, each pair of disks being mounted upon a shaft with means between the two to rotate both, the brushes on one end of the several pairs being disposed side by side in two rows across the cloth to be brushed and with the brushes in one row placed to cover the spaces between those of the other row, and means for causing the cloth to pass successively over the brushes upon each end of the pairs of disks.

706,183. SWIVEL-LOOM. James Wadsworth, Paterson, N. J. Filed Mar. 27, 1902. Serial No. 100,341. (No model.)



Claim.—1. In a swivel-loom, a suitable shuttle-support, in combination with a tapering, tongue-shaped, plate, adapted to be removably secured thereto with its narrow end projecting downwardly below the bottom, and laterally beyond the sides, thereof, substantially as set forth.

2. In a swivel-loom, the combination with the swivel-shuttle and means for operating the same, of the swivel-shuttle support and a tapering tongue-shaped plate extending downwardly behind and below the swivel-shuttle, substantially as set forth.

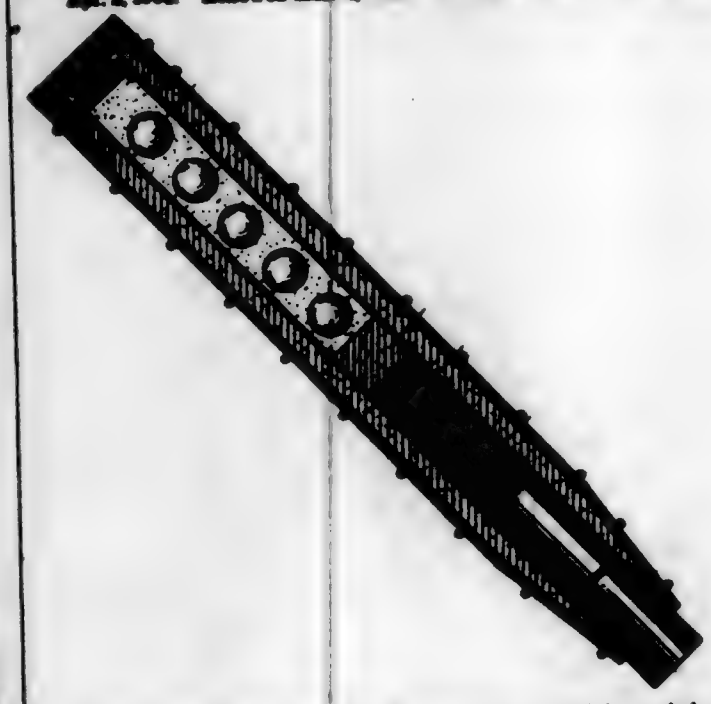
3. In a loom, the combination with a swivel-shuttle rail carrying swivel-shuttles, of a series of tapering tongue-shaped plates extending downwardly, behind, and below the shuttles, substantially as set forth.

4. In a swivel-loom, the combination with the swivel-shuttles, of a series of swivel-shuttle supports, and a series of tapering tongue-shaped plates extending downwardly below and laterally beyond the shuttles, substantially as set forth.

5. In a swivel-loom, the combination with a swivel-shuttle rail carrying swivel-shuttles, of means extending downwardly below, laterally beyond, and substantially at right angles with, the swivel-shuttles, and adapted to receive and temporarily confine a plurality of warp-threads within a smaller compass during the operation of the swivel-shuttles, than they normally occupied before the shed was opened, substantially as set forth.

6. In a swivel-loom, a swivel-shuttle and a support therefor, and means extending downwardly below, laterally beyond, and substantially at right angles with, the swivel-shuttle, and adapted to crowd into a small compass the warp-threads completing the upper plane of the shed formed for swivel-weaving, while the swivel-shuttle is passing through the shed.

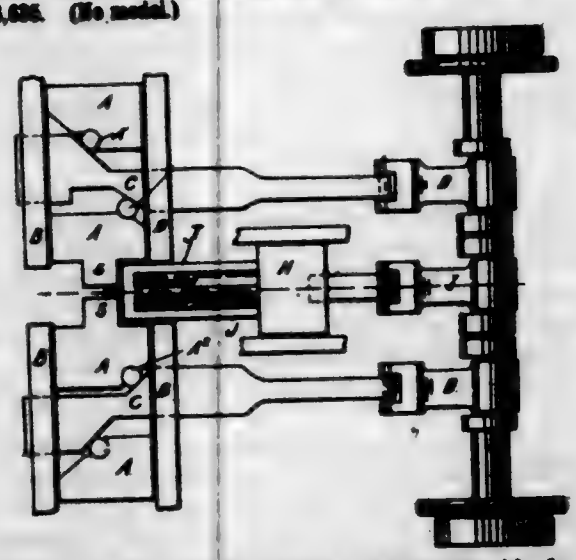
706,184. TORCH. Edward H. Warren, New York, N. Y. Filed Apr. 2, 1902. Renewed Mar. 4, 1902. Serial No. 96,603. (No model.)



Claim.—1. As a new article of manufacture, a torch consisting of a hollow tube containing pyrotechnic material, an annular layer of solid combustible material surrounding said tube and a combustible fabric inclosing said layer, substantially as shown and described.

2. As a new article of manufacture, a torch consisting of an absorbent outer layer impregnated with a suitable combustible substance such as paraffin, a tubular core and a layer of combustible substance such as paraffin interposed between the outer layer and the core, substantially as shown and described.

706,185. MEANS FOR SHAPING AND SHARPENING DRILL-BITS. John Wagner, Denver, Colo. Filed Sept. 26, 1901. Serial No. 76,626. (No model.)



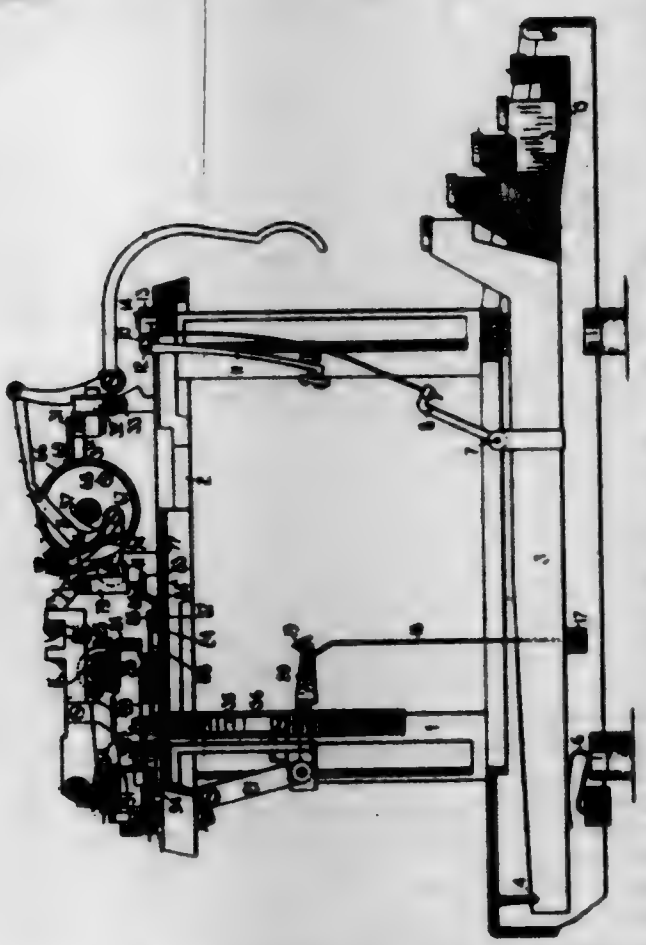
Claim.—1. In means for shaping and sharpening bits for machine rock-drills, the combination with two coöperating die-blocks, each having a wedge-shaped recess, and two other recesses each forming half of a wedge-shaped recess, each die-block having a hinged member on one side

of the wedge-shaped recess, a suitable frame on which one of the die-blocks is movably mounted, means for bringing the faces of the die-blocks together, whereby the bar from which the drill-bit is to be formed is securely held in place, means for holding the hinged members of the die-blocks closed, and means engaging one end of the drill-bit bar, for shaping the bar to conform to the wedge-shaped recesses of the die-blocks, and means for releasing the hinged members of the die-blocks, whereby they are allowed to open as the die-blocks are separated, substantially as described.

2. The combination with a suitable frame, of two die-blocks of the class described, said blocks being mounted on the frame, each block having a wedge-shaped recess adapted to conform to the shape of a wing of the cutting extremity of a drill-bit as described, the said blocks having hinged members adapted to open to allow the wing of the bit to be removed after it has been shaped to conform to the shape of the recess.

3. The combination of two coöperating die-blocks of the class described, each block having a recess adapted to conform to the shape of a part of a drill-bit or other tool, the said blocks having movable members respectively adapted to open to allow the said parts of the tool held thereby, to be removed after they have been shaped to conform to the shape of the recesses of the said blocks.

706,186. TYPE-WRITING MACHINE. MAX W. WEBB, Bowyer, N. J., assignor to Wyckoff, Seamans & Benedict, Ilion, N. Y., a Corporation of New York. Filed May 31, 1902. Serial No. 109,756. (No model.)



Claim.—1. In a type-writing machine, the combination of paper-feeding devices, printing instrumentalities and means controlled by the paper for affording a locking of said paper feeding and printing instrumentalities.

2. In a type-writing machine, the combination of a platen, type-bars, finger-keys, and means controlled by the paper for preventing a line-spacing movement of said platen and for affording a locking of the type-bars against printing.

3. In a type-writing machine, the combination of a platen, and means controlled by the paper for preventing a letter and line space movement of the platen.

4. In a type-writing machine, the combination of a carriage, a rotary platen, and means controlled automatically by the paper for locking the platen against rotation and for preventing a complete travel of the carriage in either direction.

5. In a type-writing machine, the combination of a carriage, a platen, key-actuated printing instrumentalities, line-lock mechanism, and means controlled by the paper for automatically affording an actuation of said line-lock mechanism and for locking the platen against line-spacing movement.

6. In a type-writing machine, the combination of a platen, key-actuated printing instrumentalities, line-lock mechanism, and means controlled by the platen during the line-spacing movement thereof, for affording an actuation of said line-lock mechanism.

7. In a type-writing machine, the combination of a carriage, a rotary platen carried thereby, printing instrumentalities, line-lock mechanism, controlling means carried by the carriage for actuating said line-lock mechanism, and means operatively connected to the platen for actuating said controlling means by a line-space movement of the platen.

8. In a type-writing machine, the combination of a carriage, a platen carried by said carriage, key-actuated printing instrumentalities, line-lock mechanism, a trip carried by the carriage for actuating said line-lock mechanism, a locking-wheel carried by the platen, and intermediate mechanism between said locking-wheel and trip, for moving the trip to the operative position.

9. In a type-writing machine, the combination of a carriage, a platen carried by said carriage, key-actuated printing instrumentalities, line-lock mechanism, a trip carried by the carriage for actuating said line-lock mechanism, a locking-wheel carried by the platen, intermediate mechanism between said locking-wheel and trip, for moving the trip to the operative position, and means controlled by the paper for automatically effecting an engagement between the intermediate mechanism and the locking-wheel.

10. In a type-writing machine, the combination of a carriage, a platen carried by said carriage, key-actuated printing instrumentalities, line-lock mechanism, a trip carried by the carriage for actuating said line-lock mechanism, a locking-wheel carried by the platen, intermediate mechanism between said locking-wheel and trip for moving the trip to the operative position, and means controlled by the paper for normally preventing an engagement between the locking-wheel and intermediate mechanism and for automatically effecting an engagement between said wheel and intermediate mechanism to afford an actuation of the trip and a locking of the trip when a predetermined point on the paper is reached.

11. In a type-writing machine, the combination of a platen, a movable part intermediate of the ends of the platen and which stands in the path of the paper in the introduction thereof into the machine, said movable part being maintained in one position by the paper in the machine and being adapted to automatically move to another position when an edge of the paper moves beyond said part, line-lock mechanism, and means controlled by said movable part for affording an actuation of the line-lock mechanism.

12. In a type-writing machine, the combination of a platen, a movable part maintained by the paper in one position and adapted to move to another position when an edge of the paper moves beyond said part, line-lock mechanism, means for locking the platen against line-spacing movement, and means controlled by said movable part for affording an actuation of said line-lock mechanism and platen-locking means.

13. In a type-writing machine, the combination of a platen, a locking-wheel carried thereby, a movable part maintained by the paper in one position and adapted to move automatically to another position when an edge of the paper moves beyond said part, line-lock mechanism, a trip for actuating said line-lock mechanism, locking means coöperating with the locking-wheel, for locking the platen against line-spacing movement, and means controlled by said movable part for affording an actuation of said line-lock trip and of the locking means for the platen.

14. In a type-writing machine, the combination of a carriage, key-actuated printing instrumentalities, line-lock mechanism, a movable trip on the carriage for actuating said line-lock mechanism, means controlled by the paper for moving said trip into the operative position, and means coöperating with the trip to prevent a complete travel of the carriage in either direction.

15. In a type-writing machine, the combination of a power-driven carriage, key-actuated printing instrumentalities, line-lock mechanism, a movable trip on the carriage for actuating said line-lock mechanism, means controlled by the paper for moving said trip into the operative position, and means carried by the frame of the machine and coöperating with the trip to prevent a complete travel of the carriage to the right when it has been moved to the left and for preventing a complete travel of the carriage to the left when it has been moved to the right.

16. In a type-writing machine, the combination of a power-driven carriage, key-actuated printing instrumentalities, line-lock mechanism, a movable trip on the carriage for actuating said line-lock mechanism, means controlled by the paper for moving said trip into the operative position when an edge of the paper reaches a predetermined point, and means carried by the frame of the machine and coöperating with the trip to prevent a movement of the carriage when it has been moved to the extreme right to begin a new line of writing and the trip has been moved to the operative position.

17. In a type-writing machine, the combination of a power-driven carriage, a platen carried by said carriage; key-actuated printing instrumentalities, line-lock mechanism, a movable trip on the carriage for ac-

tuating said line-lock mechanism, means controlled by the paper for moving said trip into the operative position when an edge of the paper reaches a predetermined point, means carried by the frame of the machine and coöperating with the trip to prevent a movement of the carriage when it has been moved to the extreme right to begin a new line of writing and the trip has been moved to the operative position, and means for simultaneously locking the platen against line-spacing movement.

18. The combination of a platen, a line-spacing ratchet-wheel at one end of the platen, line-spacing mechanism coöperating therewith, a line-locking wheel at the other end of the platen, and means coöperating with said locking-wheel to lock the platen against rotation.

19. The combination of a platen, a line-spacing ratchet-wheel at one end of the platen, line-spacing mechanism coöperating therewith, a line-locking wheel secured to the platen at the other end thereof, and means controlled by the paper and coöperating with said locking-wheel to lock the platen against rotation when an edge of the paper reaches a predetermined position.

20. In a type-writing machine, the combination of a carriage, printing instrumentalities, line-lock mechanism, a series of stops and a coöperating trip which are normally out of each other's path but which are adapted to actuate the line-lock mechanism and to arrest the carriage in its movement in either direction, and means controlled by the paper for moving one of said series of stop and trip elements into the path of the other.

21. In a type-writing machine, the combination of a carriage, a platen, printing instrumentalities, line-lock mechanism, and a device which is adapted to engage the platen and be moved thereby to afford an actuation of the line-lock mechanism.

22. In a type-writing machine, the combination of a carriage, a platen, printing instrumentalities, line-lock mechanism, and a device which is adapted to engage the platen and be moved thereby for a limited distance and then arrest it against line-spacing movement and to afford an actuation of the line-lock mechanism.

23. In a type-writing machine, the combination of a carriage, a platen, printing instrumentalities, line-lock mechanism, a device which is adapted to engage the platen and be moved thereby to afford an actuation of the line-lock mechanism, and means controlled by the paper for bringing about the engagement of said device with the platen.

24. In a type-writing machine, the combination of a carriage, a platen, printing instrumentalities, line-lock mechanism, an engaging device which is adapted to engage the platen and be moved thereby for a limited distance and then arrest it against line-spacing movement and to afford an actuation of the line-lock mechanism, and means controlled by the paper for normally maintaining said engaging device disengaged from the platen and for affording an engagement thereof with the platen when an edge of the paper reaches a predetermined point.

25. In a type-writing machine, the combination of a carriage, a platen carried thereby, printing instrumentalities, line-lock mechanism, a locking-wheel carried by the platen, an engaging device which is normally out of engagement with said locking-wheel but is adapted to be moved thereby, a trip carried by the carriage, and adapted to actuate said line-lock mechanism, and means for effecting an engagement between the engaging device and locking-wheel, to afford a movement of the trip and an actuation of the line-lock mechanism.

26. In a type-writing machine, the combination of a carriage, a platen carried thereby, printing instrumentalities, line-lock mechanism, a locking-wheel connected to the platen, an engaging device which is normally out of engagement with said locking-wheel but is adapted to be moved thereby for a limited distance and then arrest the line-spacing movement of the platen, a trip carried by the carriage and adapted to actuate said line-lock mechanism, and means for effecting an engagement between the engaging device and locking-wheel to afford a movement of the trip and an actuation of the line-lock mechanism and to lock the platen against line-spacing movement after the trip has been moved.

27. In a type-writing machine, the combination of a carriage, a platen carried thereby, printing instrumentalities, line-lock mechanism, a locking-wheel connected to the platen, an engaging device which is adapted to be moved by said locking-wheel, a trip carried by the carriage and adapted to actuate said line-lock mechanism, and means controlled by the paper for normally maintaining the engaging device out of engagement with the locking-wheel and for effecting an engagement between the engaging device and locking-wheel when an edge of the paper reaches a predetermined point, to afford a movement of the trip and an actuation of the line-lock mechanism.

28. In a type-writing machine, the combination of a carriage, a platen carried thereby, printing instrumentalities, line-lock mechanism, a locking-wheel carried by the platen, an engaging device which is adapted to be moved by said locking-wheel for a limited distance and then arrest the line-spacing movement of the platen, a trip carried by the carriage and adapted to actuate said line-lock mechanism, and means controlled by the paper for normally maintaining the engaging device out of engagement with the locking-wheel and for effecting an engagement between the engaging device and locking-wheel when an edge of the paper reaches a predetermined point, to afford a movement of the trip and an actuation of the line-lock mechanism and to lock the platen against line-spacing movement after the trip has been moved.

29. In a type-writing machine, the combination of a carriage, a platen carried thereby, a locking-wheel secured to rotate with said platen and having teeth thereon, a spring-pressed engaging device which is adapted to coöperate with the teeth of said locking-wheel to arrest the line-spacing movement of said platen, a spring-pressed finger which is adapted to stand in the path of the paper in its introduction into the machine and to be maintained by the paper against its spring tension, and intermediate connections between said finger and engaging device, whereby when the paper passes beyond the finger it will be released and the engaging device will be thrown into engagement with the locking-wheel.

30. In a type-writing machine, the combination of a carriage, a platen carried thereby, key-actuated printing instrumentalities, line-lock mechanism, a trip which is adapted to actuate said line-lock mechanism, a locking-wheel secured to said platen and having teeth thereon, a spring-pressed engaging device which is adapted to coöperate with the teeth of said locking-wheel to limit the line-spacing movement of said platen and to be moved thereby for a limited distance, a spring-pressed finger which is adapted to stand in the path of the paper in its introduction into the machine and to be maintained by the paper against its spring tension, and intermediate connections between said finger and engaging device and between the engaging device and said trip, whereby when the paper passes beyond the finger it will be released and the engaging device will be thrown into engagement with the locking-wheel to limit the line-spacing movement of the platen and to effect a movement of the trip and thereby bring about the locking of the line-lock mechanism.

31. In a type-writing machine, the combination of a platen, a platen-frame, a line-lock wheel secured to rotate with the platen, a spring-pressed rock-shaft carried by the platen-frame, a finger which is carried by the rock-shaft and is adapted to bear against the paper and maintain the rock-shaft against its spring tension, a crank-arm secured to said shaft and an engaging device connected to said crank-arm and adapted to engage the locking-wheel and limit the line-spacing movement of the platen when the paper passes beyond said finger.

32. In a type-writing machine, the combination of key-actuated printing instrumentalities, line-lock mechanism, a platen, a platen-frame, a line-lock wheel secured to the platen, a spring-pressed rock-shaft carried by the platen-frame, a finger which is carried by the rock-shaft and is adapted to bear against the paper and maintain the rock-shaft against its spring tension, a crank-arm secured to said shaft, an engaging device connected to said crank-arm, and adapted to engage the locking-wheel and limit the line-spacing movement of the platen when the paper passes beyond said finger, and a trip connected to said engaging device and adapted to be actuated thereby to afford a locking of the line-lock mechanism when the engaging device locks the platen against line-spacing movement.

33. In a type-writing machine, the combination of a platen, a platen-frame, a toothed line-lock wheel secured to the platen, a spring-pressed rock-shaft which extends longitudinally of the platen and is carried by the platen-frame, a finger which is rigidly secured to said rock-shaft and is adapted to bear against the paper and maintain the shaft against its spring tension, an independently spring-pressed engaging device which is provided with a locking pin or projection that is adapted to engage the teeth of the locking-wheel to arrest the line-spacing movement of the platen, and a crank-arm secured to said rock-shaft and to which the engaging device is pivoted.

34. In a type-writing machine, the combination of a carriage, type-bars, finger-keys for actuating said type-bars, line-lock mechanism, a platen, a platen-frame, a toothed line-lock wheel which rotates with the platen, a spring-pressed rock-shaft which extends longitudinally of the platen and is carried by the platen-frame, a finger which is rigidly secured to said rock-shaft and is adapted to bear against the paper, and maintain the shaft against its spring tension, an independently spring-pressed engaging device which is provided with a projection that is adapted to engage the teeth of the locking-wheel to limit the movement thereof and thus arrest the line-spacing movement of the platen, a trip or abutment carried by said engaging device and adapted to be moved to the operative position to afford a locking movement of the line-lock mechanism when the platen is locked against line-spacing movement and a crank-arm secured to said rock-shaft and to which the engaging device is pivoted.

35. In a type-writing machine, the combination of a platen, a platen-frame, a toothed line-lock wheel secured to the platen, a spring-pressed rock-shaft which extends longitudinally of the platen and is carried by the platen-frame, a finger which is rigidly secured to said rock-shaft and is adapted to bear against the paper and maintain the shaft against its spring tension, an independently spring-pressed engaging device which

is provided with a projection that is adapted to engage the teeth of the locking-wheel to arrest the line-spacing movement of the platen, a crank-arm secured to said rock-shaft and to which the engaging device is pivoted, and hand-actuated means for releasing the platen and permitting a line-spacing movement thereof.

36. In a type-writing machine, the combination of a carriage, type-bars, finger-keys for actuating said type-bars, line-lock mechanism, a platen, a platen-frame, a toothed line-lock wheel secured to the platen, a spring-pressed rock-shaft which extends longitudinally of the platen and is carried by the platen-frame, a finger which is rigidly secured to said rock-shaft and is adapted to bear against the paper and maintain the shaft against its spring tension, a crank-arm secured to said rock-shaft, an independently spring-pressed engaging device pivoted to said crank-arm and which is provided with a projection that is adapted to engage the teeth of the locking-wheel to limit the movement thereof and thus arrest the line-spacing movement of the platen, a trip or abutment carried by said engaging device and adapted to be moved to the operative position to afford a locking movement of the line-lock mechanism when the platen is locked against line-spacing movement, and hand-actuated means for releasing the platen and the line-lock mechanism.

37. In a type-writing machine, the combination of paper-feeding devices, printing devices, automatically-actuated means controlled by the paper for locking said paper-feeding and printing devices and hand-operated means for releasing said devices after they have been automatically locked.

38. The combination of a platen, key-actuated type-bars, line-lock mechanism, automatically-actuated means controlled by the paper for arresting the rotation of the platen and affording an actuation of the line-lock mechanism, and hand-operated means for releasing the platen and line-lock mechanism after they have been automatically locked.

39. In a type-writing machine, the combination of a line-spacing mechanism, letter-spacing mechanism, and means controlled by the paper for automatically locking the line-spacing and letter-spacing mechanisms.

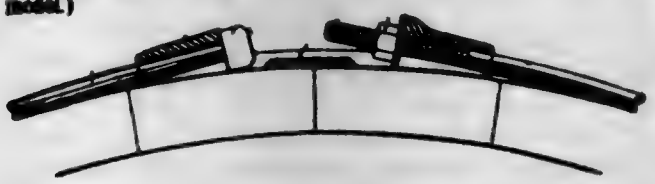
40. In a type-writing machine, the combination of line-lock mechanism, line-spacing mechanism and a spring-pressed finger which is adapted to bear upon the paper, and to be released therefrom when an edge of the paper and the printing-center attain predetermined relations one to the other, and means controlled by said finger for affording an actuation of said line-spacing and line-lock mechanisms.

41. In a type-writing machine, the combination of a carriage, a removable spring-pressed rock-shaft carried thereby, a finger carried by said rock-shaft and adapted to bear upon said paper, line-lock mechanism, line-spacing mechanism, a locking device carried by said rock-shaft, and means coöperating therewith for locking the line-spacing mechanism and for affording a locking movement of the line-lock mechanism.

42. In a type-writing machine, the combination of a carriage, a spring-pressed rock-shaft carried thereby, a paper-shield having an aperture therein and against which shield the paper is adapted to bear, a finger carried by said rock-shaft and adapted to bear upon said paper opposite the aperture in the shield, line-spacing mechanism, a locking device carried by said rock-shaft, and means coöperating therewith for locking the line-spacing mechanism.

43. In a type-writing machine, the combination of a carriage, feed mechanism therefor, a platen, a locking-wheel carried by the platen, a locking device normally maintained out of engagement with the locking-wheel by the paper and adapted to be moved into locking engagement with the wheel when the paper reaches a predetermined point relatively to the printing-center, and means controlled by said locking device for locking said carriage-feed mechanism.

706,187. CLAMP FOR TANK OR LIKE HOOPS. JOEL WHOM, San Francisco, Cal. Filed Mar. 20, 1902. Serial No. 99,294. (No model.)



Claim.—1. A clamp for tank-hoops and the like consisting of a flat malleable plate having side ribs, lugs formed upon opposite ends thereof between said ribs said lugs having slots or channels made in their inner faces to receive the opposite ends of the hoop-rod, said lugs having adjacent surfaces adapted to form contact-faces for the head at one end and the nut upon the other end of the hoop whereby the hoop and clamp form an essentially continuous surface to contact with the tank.

2. A clamp for tank and like hoops consisting of parallel bendable ribs, lugs formed at each end between said ribs having slots or channels made in their inner surfaces to receive the ends of the hoop rod and retain them in close proximity with the surface inclosed, a thin diaphragm connecting the ribs intermediate between the lugs and open spaces formed between said diaphragm and the lugs to receive the head and nut respectively of the hoop.

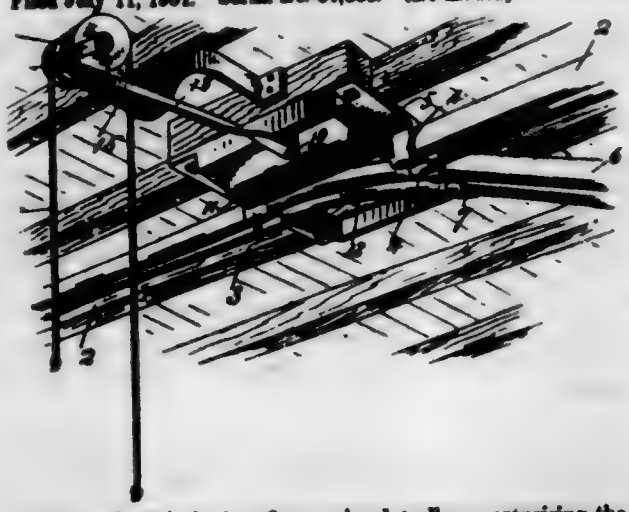
3. A clamp for tank-hoops and the like consisting of a malleable plate having one flat surface adapted to fit the curvature of the object to which it is applied and openings made through it intermediate of the ends, slots or channels extending from said openings to the ends, and raised lugs upon the outer surface of the plate into which said slots extend, said lugs having faces of contact against which the head and nut respectively of the hoop are supported.

706,188. MORTAR COMPOSITION. EDWIN R. WELCH, Philadelphia, Pa. Filed Dec. 20, 1901. Serial No. 86,721. (No specimens.)

Claim.—1. A composition of matter adapted with the addition of water to form a mortar or plastering material, the said composition consisting of ground or crushed unslaked lime, ground or crushed cinder, jute and litharge, all mechanically combined in a substantially dry state.

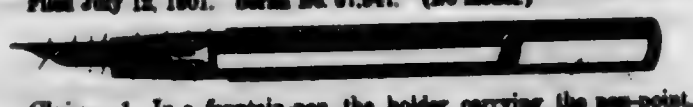
2. A composition of matter adapted with the addition of water to form a mortar or plastering mixture or composition, consisting of twenty-five per cent. of ground or crushed unslaked lime, sixty per cent. of ground or crushed cinder, ten per cent. of jute and five per cent. of litharge, all mechanically combined in a substantially dry state.

706,189. SWITCH FOR OVERHEAD TUBULAR TROLLEY-TRACKS. PAUL F. WERNER, Williamsett, Mass., assignor to Coburn Trolley Track Manufacturing Company, Holyoke, Mass., a Corporation. Filed July 11, 1901. Serial No. 67,360. (No model.)



Claim.—Switch devices for overhead trolleys comprising the main frame 5 having a rectangular opening therein and the pending brackets 3 and 4, a side bracket 7 thereunder, and the ledges 10 in the opposite borders thereof, combined with the plate 8 having borders for engagement on said ledges, and slidable in said frame 5, and the track-sections 11 and 12 under said plate 8, registrable with said brackets 3 and 4 through sliding movements of the frame 8 in the frame 5, and means for moving said frame 8, substantially as set forth.

706,140. FOUNTAIN-PEN. PAUL E. WIRT, Bloomsburg, Pa. Filed July 12, 1901. Serial No. 67,947. (No model.)



Claim.—1. In a fountain-pen, the holder carrying the pen-point, and a tubular feeder having at its lower closed end an offset feeding-foot provided with an expanded capillary attractive surface in contact with the nib portion of the pen-point and constituting the sole external capillary area of the feeder, and also provided with an ink-flowing fissure piercing said surface and communicating with the interior passage through the feeder, the latter being spaced from the pen-point to provide a non-attractive space above said capillary surface and provided within the zone of said space with an air-vent disposed in close relation to the intake of the fissure and more remotely removed from the capillary surface supplied thereby, the passage-way in the feeder being open and entirely unobstructed between the vent and said fissure.

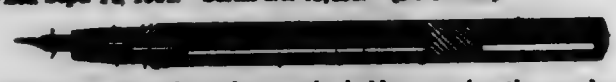
2. In a fountain-pen, the holder carrying the pen-point and a tubular feeder having at its lower closed end a laterally-offset feeding-foot provided with an expanded prolate capillary attractive surface in contact with the nibs and constituting the sole external capillary area of the feeder, and also provided with an ink-flowing fissure piercing said surface and communicating with the interior passage-way of the feeder, the latter being spaced from the pen-point to provide a non-attractive space above

said capillary surface and provided within the zone of said space with an air-vent disposed in close relation to the intake of the fissure and more remotely removed from the capillary surface supplied thereby, the passage-way in the feeder being open and entirely unobstructed between the vent and said fissure.

3. In a fountain-pen, the holder carrying the pen-point, a tubular feeder provided with a lower closed end having a laterally-offset feeding-foot formed with an expanded capillary surface in contact with the nibs and pierced by an ink-flowing fissure located a distance above the lower end of the passage-way through the tube to provide at such end an auxiliary supply chamber or pocket, said feeder-tube being further provided with an air-vent disposed in close relation to the intake of the fissure and having the passage-way in the tube entirely open and unobstructed between the vent and said fissure, and supplementary means for positively feeding ink from the main column into the auxiliary supply chamber or pocket.

4. In a fountain-pen, the holder carrying the pen-point, a tubular feeder provided with a lower closed end having a laterally-offset feeding-foot formed with an expanded capillary surface in contact with the nibs and pierced by an ink-flowing fissure located a distance above the lower end of the passage-way through the tube to provide at such end an auxiliary supply chamber or pocket, said feeder-tube being further provided with an air-vent disposed in close relation to the intake of the fissure and having the passage-way in the tube entirely open and unobstructed between the vent and said fissure, and a supplementary feeding-shaft disposed longitudinally within the passage-way of the tube and extending the full length thereof, the lower extremity of said shaft projecting into the auxiliary supply chamber or pocket.

706,141. FOUNTAIN-PEN. Paul B. Wirt, Bloomsburg, Pa. Filed Sept. 14, 1901. Serial No. 75,408. (No model.)



Claim.—1. In a fountain-pen, the holder carrying the pen-bearing section, a full-headed pen-point fitting within said section and having the edge flanges, a separate detachable top feeder arranged within the pen-bearing section and extending over the top side of the pen-point, and an approximately cylindrical vented plug having a close fit within the pen-bearing section and also tightly registering within the concavity of the pen-point heel and against the edge flanges thereof, said plug and separate top feeder constituting clamping members for holding the pen-point therebetween.

2. In a fountain-pen, the reservoir-holder carrying the pen-point, the feeder, and an interior dam having a body constructed to provide an impulse-check at the bottom of the reservoir, and also to provide an area extending along the feeder contiguous to the pen-point for the circulation of ink downward and air upward.

3. In a fountain-pen, the reservoir-holder carrying the pen-point, a feeding-shaft, and an interior dam having a body constructed to provide an impulse-check at the bottom of the reservoir, and also to provide an area extending along the feeding-shaft contiguous to the pen-point for the circulation of ink downward and air upward.

4. In a fountain-pen, the holder carrying the pen-point, a feeding-shaft, and an interior dam having a body constructed to provide an impulse-check at the bottom of the reservoir, said body also being constructed to permit the circulation of air upward and to concentrate the flow of ink along the portion of the feeder contiguous to the heel of the pen-point.

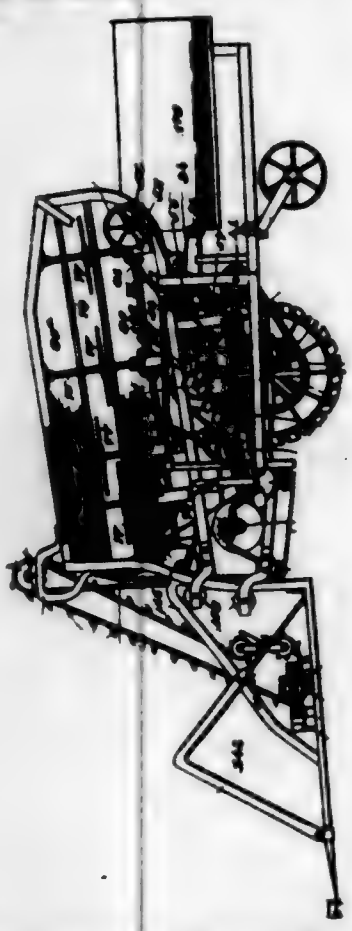
5. In a fountain-pen, the reservoir-holder carrying the pen-point, the feeding-shaft, and an interior dam comprising a plug-body constructed to provide an impulse-check at the bottom of the reservoir and having in its side next to the feeding-shaft an extended seat receiving the shaft and forming an extended circulation area along the shaft contiguous to the heel of the pen-point.

6. In a fountain-pen the reservoir-holder carrying the pen-point, the feeding-shaft, and an interior dam comprising a plug-body constructed to provide an impulse-check at the bottom of the reservoir and provided at the side next to the feeding-shaft with a channeled seat receiving the latter and also with a fissure or groove in the base of said seat, the latter constituting an extended circulation area along the inner portion of the shaft contiguous to the heel of the pen-point.

7. In a fountain-pen the reservoir-holder carrying the pen-point, a pen-holding plug bearing against the pen-point, a feeding-shaft overlying the pen-point, and a supplemental vented plug arranged in the pen-bearing section and directly adjoining the pen-holding plug, said supplemental plug being constructed to provide an impulse-check at the bottom of the reservoir, and also to provide an area extending along the shaft for the circulation of ink downward.

8. In a fountain-pen, the reservoir-holder carrying the pen-bearing section, a pen-point, a vented plug fitting within the pen-bearing section and bearing against the pen-point, a feeding shaft or tongue overlying the pen-point and extending through the pen-bearing section, and an impulse check or dam consisting of a supplemental plug arranged in the pen-bearing section above the pen-holding plug and having a circulation area lying next to the feeding shaft or tongue.

706,142. CORN-HARVESTER. James R. Wood, Harvard, Ill., assignor to Edwin C. Haymon, trustee, Chicago, Ill. Filed July 5, 1901. Serial No. 67,216. (No model.)



Claim.—1. In a corn-harvester, the combination with a frame having a longitudinal opening therein adapted to straddle a row of corn, of levers pivoted to said frame upon each side of said opening and pointing crosswise of the line of draft, and mechanism adapted to give to the inner and operative end of said levers a downward and inward movement crosswise of the line of draft, then a relatively rapid upward movement, then a movement downward and outward to the point of beginning, substantially as described.

2. In a corn-harvester, the combination with a frame having a longitudinal opening therein adapted to straddle a row of corn, of a forwardly-projecting pin fixed to said frame, a lever provided with a longitudinal slot intermediate its ends adapted to engage said pin and support said lever with its inner and operative end pointing crosswise of said longitudinal opening and crosswise of the line of draft, a crank having its wrist-pin pivoted to the other end of said lever, and mechanism for rotating said crank, substantially as described.

3. In a corn-harvester, the combination with a frame having a longitudinal opening therein adapted to straddle a row of corn, of forwardly-projecting pins fixed upon said frame upon each side of said opening, levers provided each with a longitudinal slot intermediate its ends adapted to engage said pins and support said levers with their inner and operative ends pointed crosswise of said opening in said frame and crosswise of the line of draft, cranks having their wrist-pins pivoted to the other ends of said levers, and mechanism for rotating said cranks, substantially as described.

4. In a corn-harvester, the combination with a sprocket-chain having fingers adapted when said chain is moved to engage partially-lifted corn and lift the same to a substantially upright position and mechanism for driving said sprocket-chain, of a lever adapted when operated to engage down corn lying along the line of draft and lift the same into engagement with said sprocket-chain, and means for giving the operative end of said lever a movement across the line of draft and upward, substantially as described.

5. In a corn-harvester, the combination with a sprocket-chain having fingers adapted when said chain is moved to engage partially-lifted down corn and lift the same to a substantially upright position and mechanism for driving said sprocket-chain, of a lever operating substantially at right angles to the line of draft and adapted when operated to engage

down corn lying along the line of draft and lift the same into engagement with said sprocket-chain, and means for giving the operative end of said lever a movement across the line of draft and upward.

6. In a corn-harvester, the combination with a pair of sprocket-chains adapted to straddle a row of corn and provided with fingers adapted when said chains are moved to engage partially-lifted corn and raise the same to a substantially vertical position, of a pair of levers operating crosswise of the draft and adapted to engage down corn lying forward or backward along the line of draft and lift the same into engagement with the said sprocket-chains, and mechanism for giving the operative end of said levers a movement across the line of draft and upward, substantially as described.

7. In a corn-harvesting machine, the combination with a frame provided with a longitudinal opening adapted to straddle a row of corn, a pair of sprocket-chains carried by said frame, one upon each side of said opening, adapted to straddle a row of corn and provided with fingers adapted as said machine is driven forward to engage partially-lifted corn and lift it to a vertical position, and means for moving said sprocket-chains, of movable arms operating crosswise of said opening in said frame, in advance of said sprocket-chains, and adapted by their movement to engage down corn lying either forward or backward along the line of draft and to lift the same into engagement with said sprocket-chains, and means for operating said arms, substantially as described.

8. In a corn-harvesting machine, the combination with a frame provided with a longitudinal opening adapted to straddle a row of corn, a pair of sprocket-chains carried by said frame, one upon each side of said opening, adapted to straddle a row of corn and provided with fingers adapted as said machine is driven forward to engage partially-lifted corn and lift it to a vertical position, and means for moving said sprocket-chains, of levers pivotally mounted upon each side of the longitudinal opening in said frame, in advance of said sprocket-chains and pointing substantially at right angles with the line of draft, and mechanism adapted to give to the operative ends of said levers a downward and inward movement crosswise of the line of draft, and thence upward, substantially as described.

9. In a corn-harvesting machine, the combination with lifting mechanism for down corn, consisting of a lever pivotally mounted near the front end of the machine and pointing substantially at right angles with the line of draft, mechanism adapted to give to the operative end of said lever a downward and inward movement across the line of draft, and thence upward, a pair of sprocket-chains located behind said lifting mechanism adapted to straddle a row of corn and provided with fingers adapted as said machine is driven forward, to engage the corn when partially lifted by said lifters and lift said corn to a vertical position as it passes between said sprocket-chains, and means for moving said sprocket-chains, substantially as described.

10. In a corn-harvesting machine, the combination with a frame provided with a longitudinal opening through which standing corn may pass, of lifters for down corn, consisting of levers pivotally mounted near the front of said frame at each side of said opening and pointing toward each other substantially at right angles with the line of draft, mechanism adapted to give to the operative ends of said levers, alternately, a downward and inward movement toward each other across said opening, and then upward, a pair of sprocket-chains on each side of said opening located behind said lifting mechanism and adapted to straddle a row of corn and provided with fingers adapted, as said machine is driven forward, to engage the corn when partially lifted by said lifting devices and to lift said corn to a vertical position as it passes between said sprocket-chains, and means for moving said sprocket-chains, substantially as described.

11. In a corn-harvesting machine, the combination with devices adapted to lift down corn toward a vertical position, of a pair of sprocket-chains adapted to straddle a row of corn and provided with curved fingers, which, when in their operative position, curve first inward, then downward and inward, adapted, as said machine is driven forward, to engage the corn when partially lifted by said lifting devices and to lift said corn to a vertical position as it passes between said sprocket-chains, and means for moving said sprocket-chains, substantially as described.

12. In a corn-harvesting machine, the combination with a knife adapted to sever stalks of standing corn, of a rotating cone provided with a spiral flange adapted, when said cone is rotated, to move the butts of the corn backward in the machine, means for rotating said cone, a plurality of rods adapted in their rotation to successively engage the stalks of corn at some distance above the butts and to cooperate with said cone in carrying the stalks of corn back in a substantially vertical position, and mechanism for rotating said rods, substantially as described.

13. In a corn-harvesting machine, the combination with an axle, carrier-wheels mounted thereon, and a rear frame journaled on said axle and adapted to carry corn-binding and bundle carrying and dropping mechanism, of a central tilting frame adapted to carry corn-harvesting mechanism and journaled on said axle, springs connecting the rear part of said central frame to said rear frame and tending to balance said central frame on said axle, and mechanism adapted to tilt said central frame upon said axle and secure it in any desired position thereon, substantially as described.

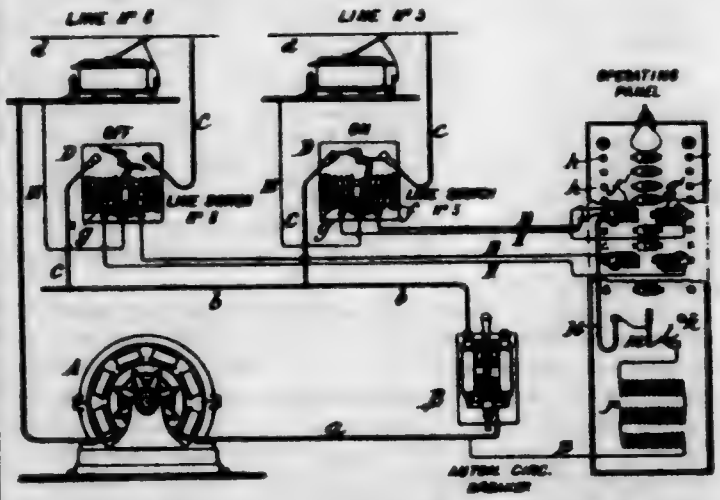
14. In a corn-harvesting machine, the combination with a rear frame adapted to carry corn-binding and bundle carrying and dropping mechanism, and a central or tilting frame adapted to carry corn cutting and forwarding mechanism, of a front frame adapted to carry corn-lifting mechanism and slidingly mounted on said central frame, and means for raising and lowering said front frame on said central frame, substantially as described.

15. In a corn-harvesting machine, a weeder, consisting of two arms pivotally mounted near the front of said machine and separated from one another at their forward ends and provided with downward-projecting plates extending across the under side of said arms, and springs adapted to yieldingly hold said arms together at a point back of their forward ends, substantially as described.

16. In a corn-harvesting machine, the combination with an axle, wheels mounted on said axle, and a rear frame journaled on said axle and adapted to contain corn-binding and corn carrying and dumping mechanism, of a caster-wheel pivoted on said rear frame and having a movement on its pivotal points in a horizontal and in a vertical arc, and a spring connected with said caster-wheel and said rear frame, substantially as described.

17. In a corn-harvesting machine, the combination with a binder-platform, consisting of a fixed and a hinged portion, of framework, two segments mounted in said framework and adapted to swing about a central longitudinal axis and, when closed together at their lower ends, to receive bundles of corn from a binder, mechanism adapted to swing said segments apart from one another at their lower edges and drop contained bundles of corn, one of said segments being adapted, when so swung, to engage the hinged portion of said binder-platform and lift the same into a substantially vertical position, substantially as described.

706,148. **MEANS FOR CONTROLLING ELECTRIC CIRCUITS.** JAMES J. WOOD, Fort Wayne, Ind. Filed June 28, 1901. Serial No. 66,334. (No model.)



(Claim.—1. In an electric distributing system the combination of a dynamo, a main-circuit conductor and branch lines normally fed therefrom, an automatic circuit-breaker in the main circuit at the central power-station, a line-switch in each line, and means for operating said line-switches from said power-station.

2. In an electric distributing system the combination of a dynamo, a main-circuit conductor and branch lines fed therefrom, an automatic circuit-breaker in the main circuit, a line-switch in each line, means for operating said line-switches from the central power-station, and indicators at said station connected to said operating means and adapted to indicate the condition of the corresponding line-switches.

3. The combination with a dynamo and main-circuit and branch lines normally fed therefrom, of an automatic circuit-breaker in the main circuit electromagnetically-operated line-switches controlling the respective lines, circuit-wires leading from said switches to the central station, and circuit-closing means at said station adapted to send a current over any wire to operate the corresponding line-switch.

4. The combination with a dynamo and main circuit and branch lines fed therefrom, of electromagnetically-operated line-switches controlling the respective lines, circuit-wires leading from said switches to the central station, circuit-closing means at said station adapted to send a current over any wire to operate the corresponding line-switch, and electromagnetic indicators at said station corresponding to the respective line-switches and connected to said wires to be operated by the same current which oper-

ates the line-switch, and adapted to indicate the condition of the respective line-switches.

5. The combination with a dynamo and main circuit and branch lines fed therefrom, of line-switches controlling the respective lines, each switch having two oppositely-acting electromagnets for opening and closing the switch respectively, a pair of circuit-wires leading from the respective magnets of each switch to the central station, indicators at said station corresponding to the respective line-switches, each having two magnets connected respectively in the two wires leading from the corresponding line-switch, and circuit-closing means at the central station for sending a current over either wire to any line-switch, whereby to operate said switch and simultaneously to operate the indicator therefor to show the condition of the line-switch.

6. The combination with a dynamo and main circuit and branch lines fed therefrom, of electromagnetically-operated line-switches controlling the respective lines, circuit-wires leading from said switches to the central station, and there terminating in sockets, and a plug connected to a source of electric current and adapted to be inserted in any of said sockets to send a current over any wire to operate the corresponding line-switch.

7. The combination with a dynamo and main circuit and branch lines fed therefrom, of electromagnetically-operated line-switches controlling the respective lines, circuit-wires leading from said switches to the central station and there terminating in sockets, electromagnetic indicators at said station corresponding to the respective line-switches and connected to said wires, and a plug connected to a source of electric current and adapted to be inserted in any of said sockets to send a current over any wire to operate the corresponding line-switch and indicator.

8. The combination with a dynamo and main circuit and branch lines fed therefrom, of line-switches controlling the respective lines, each switch having two oppositely-acting electromagnets for opening and closing the switch respectively, a pair of circuit-wires leading from the respective magnets of each switch to the central station, indicators at said station corresponding to the respective line-switches, each having two magnets connected respectively in the two wires leading from the corresponding line-switch, said indicators arranged in a consecutive series, with terminals for said wires arranged also in consecutive series opposite their respective indicators, and circuit-closing means for connection with any of the respective terminals for sending a current over either wire to any line-switch, whereby to operate said switch and simultaneously to operate the indicator therefor to show the condition of the line-switch.

9. In a system for controlling electric circuits, the combination with electromagnetically-operated switches and wires leading thence to a central station, of operating means at said station comprising a series of circuit-terminals for said wires, a series of indicators having electromagnets operatively connected in the circuits of the respective wires, and circuit-closing means adapted to coact with said terminals to send a current over any of the wires to operate the magnets of the line-switch and indicator in connection with such wire.

10. In a system for controlling electric circuits, the combination with electromagnetically-operated switches and wires leading thence to a central station, of operating means at said station comprising a series of circuit-terminals for said wires, arranged consecutively, a series of indicators arranged consecutively and opposite the corresponding terminals, said indicators having electromagnets connected in the circuits of the respective wires, and circuit-closing means adapted to coact with said terminals to send a current over any of the wires to operate the magnets of the line-switch and indicator in connection with such wire.

11. In a system for controlling electric circuits, the combination with electromagnetically-operated switches and wires leading thence to a central station, of operating means at said station comprising a series of electromagnetic indicators arranged consecutively, two series of circuit-terminals for said wires arranged consecutively and opposite the respective indicators, and circuit-closing means adapted to coact with said terminals to send a current over any of the wires to operate the magnets of the line-switch and indicator in connection with such wire.

12. In a system for controlling electric circuits, the combination with electromagnetically-operated switches and wires leading thence to a central station, of indicators at said station comprising each a pair of electromagnetic coils, a movable member arranged to be attracted in opposite directions by the respective coils, and an indicating-tablet connected to and moved by said movable member.

13. In a system for controlling electric circuits, the combination with electromagnetically-operated switches and wires leading thence to a central station, of indicators at said station comprising each a pair of electromagnetic coils arranged in line, a core movable within said coils and attracted by each in an opposite direction, and an indicating-tablet connected to and moved by said core.

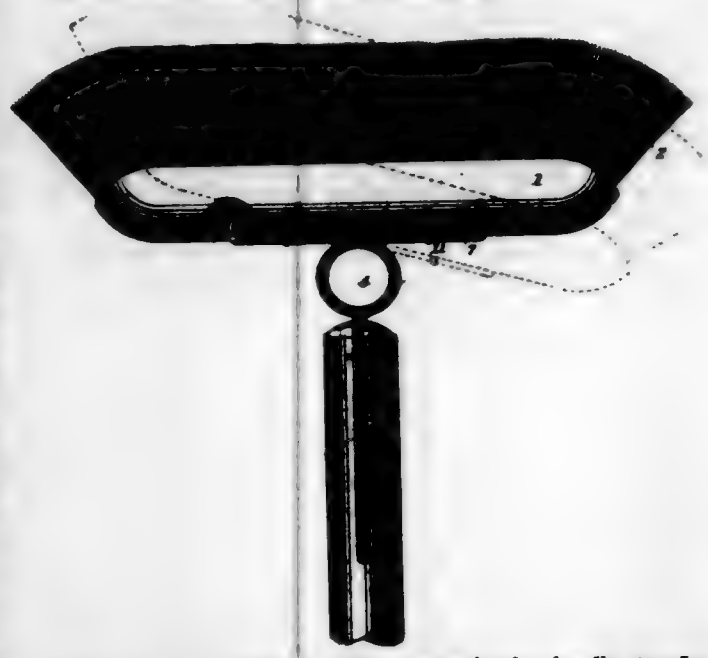
14. In a system for controlling electric circuits, the combination with electromagnetically-operated switches and wires leading thence to a central station, of indicators at said station comprising each a pair of electromagnetic coils f' and g', arranged in line, a core p movable within said coils, an indicating-tablet q, and a stem s connecting said tablet to said core.

15. In a system for controlling electric circuits, the combination with electromagnetically-operated switches, and wires leading thence to a central station, of indicators at said station, comprising each a pair of electromagnetic coils, and a movable member arranged to be attracted in opposite directions by the respective coils, and a retaining device coacting with said movable member for holding it in either position until attracted to the other.

16. In a system for controlling electric circuits, the combination with electromagnetically-operated switches and wires leading thence to a central station, of indicators at said station comprising each a pair of electromagnetic coils f' and g', arranged in line, a core p movable within said coils, an indicating-tablet q connected to said core by a stem s, and a spring t engaging said stem to hold the core and tablet against displacement.

17. In an electric distributing system, the combination of a dynamo, a main-circuit conductor and branch lines normally fed therefrom, an overload-indicator in the main circuit at the central power-station, a line-switch in each line, and means for operating said line-switches from said power-station.

706,144. BROOM, &c. McCLINTOCK YOUNG, Frederick, Md., assignor to the Palmetto Fibre Company, a Corporation of Illinois. Filed Apr. 1, 1902. Serial No. 100,847. (No model.)



Claim.—1. In combination with a broom-head, a handle therefor, and an intermediate coiled spring disposed transversely of the axis of the handle and rigidly connected at its opposite ends respectively with the head and handle, and serving as the sole means for connecting the head with the handle; whereby the movement of the head in one direction transversely will subject the spring to a torsional strain and the movement in another direction transversely will compress and separate the coils respectively at opposite sides.

2. In combination with a broom-head, a handle therefor, an intermediate coiled spring arranged transversely of the axis of the handle, said spring having its ends extended at right angles to each other and firmly secured respectively to the handle and head.

3. In combination with a broom-head, a handle therefor, two intermediate coiled springs arranged end to end and disposed transversely of the axis of the handle, and each connected at its ends respectively with the head and handle, and serving as the sole means for connecting the head with the handle.

4. In combination with a broom-head, a handle, and two reversely-disposed coiled springs each having their opposite ends secured respectively to the head and handle, and jointly serving as the sole means for connecting the head with the handle.

5. In combination with a head, a handle therefor, and two reversely-disposed coiled springs arranged end to end with adjacent ends extended in opposite directions and secured to the head, and the opposite ends extended in the same direction and secured to the handle.

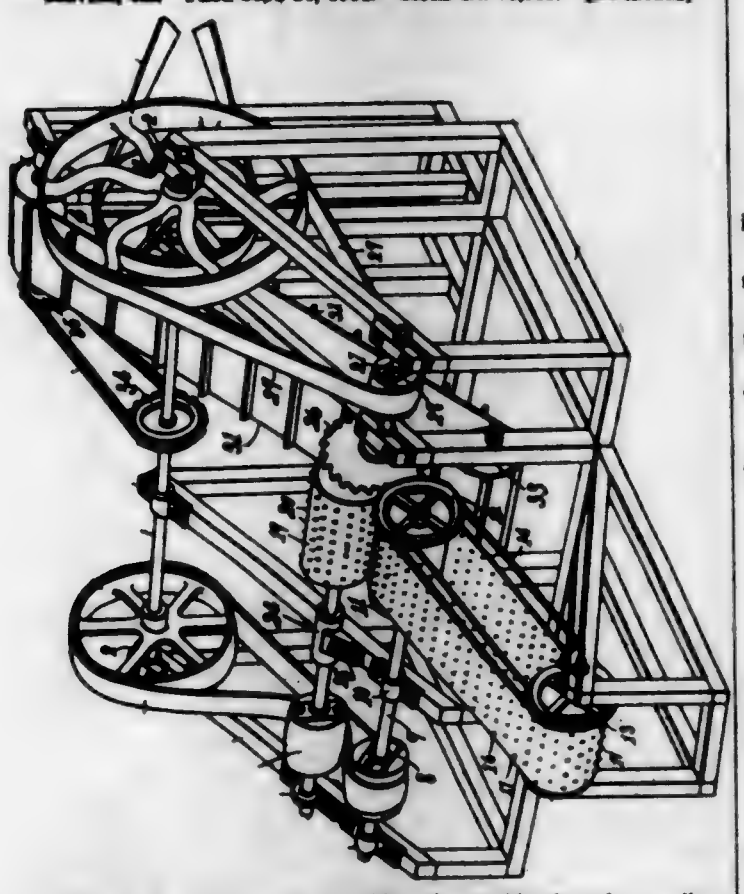
6. In combination with a grooved head, a handle provided with grooves in its side, and intermediate coiled springs having their ends extended and seated and secured in grooves in the head and handle.

7. In combination with a longitudinally-grooved head a handle formed in its sides with grooves, said grooves being formed at the ends

with holes, intermediate coiled springs provided with extensions extending respectively in the grooves in the head and handle, and said extensions having on their ends tangs seated in the holes at the ends of the grooves, and staples straddling the extensions adjacent to the coils and extending in the head and handle.

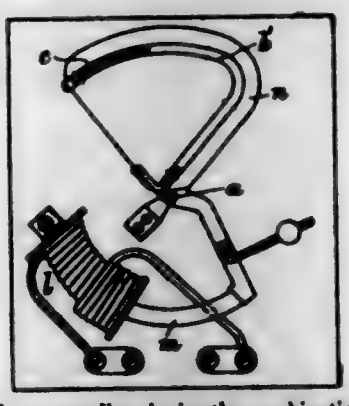
8. In combination with a broom-head, a handle therefor, and an intermediate flexible connection formed of open spring-coils arranged at the back of the broom, the said coils presenting an unobstructed opening which may be passed over a nail or similar support.

706,145. BEET-TOPPING MACHINE. JOSEPH ALBRIGHT, Watsonville, Cal. Filed Sept. 26, 1901. Serial No. 76,595. (No model.)



Claim.—In a beet-topping machine, the combination of an endless carrier running around horizontal shafts at its ends, and having suitable spikes to hold the beet in a fixed position on the upper surface thereof, a roller rolling opposite to the end of the carrier and mounted on a movable horizontal shaft substantially parallel to the horizontal shaft at the delivery end of the carrier, the opposite or nearest rolling-surfaces of the roller and carrier being vertical, and a circular saw mounted on a shaft substantially parallel with said last-named shaft, substantially as described.

706,146. MECHANISM FOR RECORDING OR REGISTERING THE MAXIMUM MOVEMENT OF ANY MECHANISM. LLEWELYN R. ATKINSON, London, England. Filed May 12, 1902. Serial No. 106,959. (No model.)



Claim.—1. In a recording device the combination with the moving part, the movement of which is to be recorded, of a movable part cooperating therewith and normally held by gravity in a position of equilibrium relative to the moving part, said movable part moving to a second position of equilibrium when a certain angular movement of the part to be measured has taken place, substantially as described.

2. In a recording device, the combination with the moving part, the movement of which is to be recorded, of a channeled movable part cooperating therewith and a rolling element carried by said channel and adapted to pass from one position of equilibrium to another when a given angular movement of the channeled part has taken place, substantially as described.

3. In a recording mechanism in combination an electromagnet, an armature, a pivoted arm carrying said armature, a curved tube or channel carried by said arm and a rolling element in said tube or channel substantially as described.

706,147. BRAKE-SHOE-LUBRICATING FILLER. RICHARD D. BALDWIN, Chicago, Ill., assignor of one-half to Harry H. Wright, Chicago, Ill. Filed Oct. 26, 1901. Serial No. 80,062. (No specimens.)

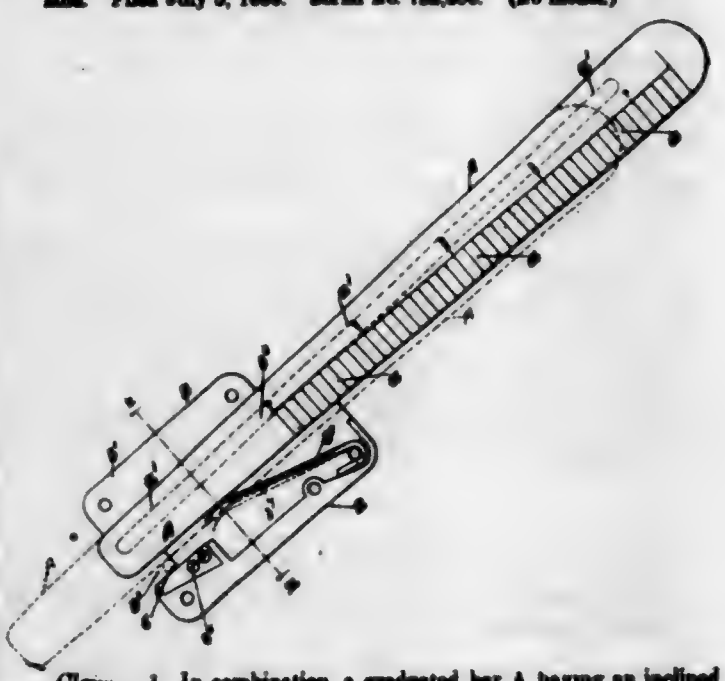
Claim.—1. A composition for brake-shoes comprising comminuted iron and pine-tar pitch.

2. A composition for brake-shoes comprising comminuted iron, pine-tar pitch and resin.

3. A composition for brake-shoes comprising comminuted iron, pine-tar pitch, resin and alum.

4. A composition for brake-shoes comprising comminuted iron, pine-tar pitch, resin, tallow and alum.

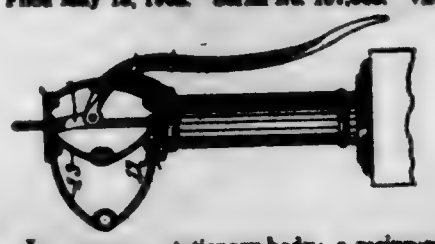
706,148. MICROMETER. CHARLES J. BAKER, Washington, England. Filed July 5, 1899. Serial No. 722,856. (No model.)



Claim.—1. In combination, a graduated bar A having an inclined edge and provided with a groove a' at one side parallel to the inclined edge, and a box B having a recess in which the bar A can slide, one side of the recess being inclined similarly to the inclined edge of the bar, a projection b^6 for engaging the groove a', and a spring b^7 bearing on the bar, substantially as described.

2. In combination, a graduated bar A having an inclined edge and provided with a groove a' at one side parallel to the inclined edge, and a box B, having a recess in which the bar A can be slid, one side of the recess being inclined similarly to the inclined edge of the bar A, a projection b^6 for engaging in the groove a', a notch or gap b^8 at one end, an extended graduated portion at the other end, and a spring b^7, all arranged and adapted for operating substantially as described.

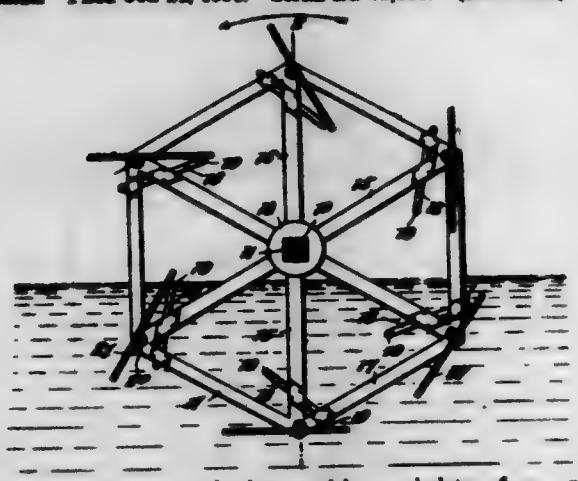
706,149. PUMP-SPRING CONNECTION. JAMES O. BASS, Wasson, Minn. Filed May 13, 1902. Serial No. 107,665. (No model.)



Claim.—In a pump, a stationary body; a reciprocating piston-rod; a spring base-plate supported on the body and another spring base-plate

secured to the piston-rod; the said base-plates having studs projecting from their adjacent faces, each of the said studs being cut of round and having its outer face shaped as an arc of a circle from a center located near the base of the opposite side of the stud; a series of U-shaped springs provided each with an open loop at its end shaped to engage one of the said studs, and a pin removably located in the stud just beyond the path of the spring, substantially as described.

706,150. WATER-WHEEL. THOMAS S. BARWIS, Vancouver, Canada. Filed Oct. 21, 1901. Serial No. 79,290. (No model.)



Claim.—1. A power-wheel comprising a skeleton frame, paddles independently hung on said frame, and a pair of stops for each paddle and carried by the frame, said stops being located on opposite sides of a line passing through the pivot of the paddle and perpendicular to a line connecting the two stops; each stop of the pair being disposed in the path of the paddle, and one stop of each pair being located closer to the pivot of the paddle than the other stop of said pair, whereby the stops act alternately to hold one paddle in two operative positions, when below the axis of motion of the wheel, and said paddle is free to lie in the plane of movement of the fluid at the lowest point to which it may be carried on the rotation of the wheel.

2. A power-wheel comprising a skeleton frame having radial arms, paddles hung eccentrically on said arms, and stop-frames extending diagonally across the arms, and each frame having a member extending between said arms, said members of each frame being disposed in the path of the unequal portions of one paddle and on opposite sides of a line passing through the pivot thereof, and perpendicular to a line connecting the two frame members, one member of each stop-frame being located closer to the pivot of said paddle than the other member of said frame, as and for the purposes set forth.

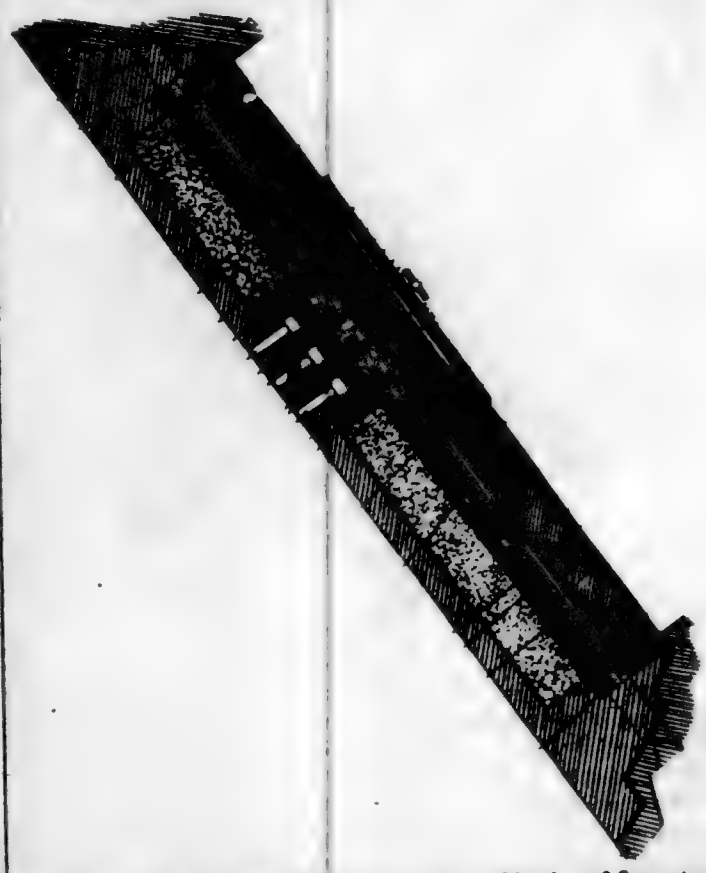
706,151. POWER-HAMMER. WILLIAM BAUERSMEISTER, Columbus, Ohio, assignor to the Hayden-Corbett Chain Company, Columbus, Ohio, a Corporation of New Jersey. Filed Feb. 7, 1902. Serial No. 93,954. (No model.)

Claim.—1. In combination with a hammer-shank, means for latching or holding the same in elevated or striking position, a lock for said hammer-holding device, a laterally-shiftable cam device for varying the strength of the blows and means for automatically operating said lock to permit the release of the hammer-holding device when the cam device has reached a definite position, substantially as described.

2. In combination with a hammer-shank, means for automatically latching or holding the same in elevated or striking position, a lock for said hammer-holding device, a laterally-shiftable cam device for varying the strength of the blows, and means for automatically operating said lock to permit the release of the hammer-holding device when the cam device has reached a definite position, substantially as described.

3. In combination with a hammer-shank, a cam device for lifting and dropping the same, means for catching and holding the hammer-shank in elevated or striking position, a lock for said hammer-shank-holding device, and means for automatically operating said lock to permit the release of the hammer-shank-holding device when the cam device has reached a definite position, substantially as described.

706,152. PERMUTATION-LOCK. WILLIAM BERER, Brooklyn, N. Y., assignor of twenty-one thirtieths to James H. Doremus, Brooklyn, N. Y. Filed Aug. 28, 1899. Renewed Dec. 27, 1901. Serial No. 87,437. (No model.)



Claim.—1. In a permutation-lock, the combination of finger-keys, tumblers actuated thereby, a lock-plate sustained by the tumblers, a slide controlled by the lock-plate and a bolt having connection with the slide to be actuated therefrom.

2. In a permutation-lock, the combination of finger-keys, tumblers actuated thereby, a lock-plate held by the tumblers, a slide controlled by the lock-plate, and a bolt actuated by the slide.

3. In a permutation-lock, the combination of finger-keys, tumblers actuated thereby, a lock-plate sustained in locked position by the tumblers, a bolt, and means for throwing the same such means being released by the fall of the lock-plate.

4. In a lock for safe-doors, the combination with a door having a cavity therein, of a block mounted in the cavity, finger-keys mounted to move in the block and in the front wall of the door, plates mounted rigidly in the cavity of the door rearward of the block and having slots therein registering with the finger-keys, a vertically-sliding lock-plate mounted between the rigid plates, tumblers mounted in the slots of the rigid plates and working with the lock-plate, the tumblers being actuated by the finger-keys, and bolt mechanism controlled by the lock-plate.

5. In a lock for safe-doors, the combination with the door having a cavity formed therein and opening at the rear thereof, of a block mounted in the cavity and bearing against the front wall of the door, finger-keys mounted to move in the block and in the front wall of the door, a number of rigid plates mounted in the cavity rearward of the block and having slots registering with the finger-keys, a lock-plate mounted to move vertically between the rigid plates, tumblers mounted in the slots of the rigid plates and coacting with the lock-plate, the tumblers being actuated from the finger-keys, a slide controlled by the lock-plate, and bolt mechanism actuated by the slide.

6. In a lock, the combination of an actuated lock-plate, a spring-

pressed dog carried thereon, a slide mounted to move relatively to the lock-plate and normally held by the dog, the movement of the lock-plate releasing the dog from the slide, and bolt mechanism having connection with the slide to be actuated thereby.

7. In a lock, the combination of an actuated sliding lock-plate having a groove in the face thereof, a slide movable through the groove, a spring-pressed dog carried by the lock-plate and engaging the slide to hold the same, and bolt mechanism having connection with the slide.

8. In a lock, the combination of a lock-plate, means for holding the lock-plate and for permitting the same to drop, a slide movable relatively to the lock-plate, a dog carried by the lock-plate and engaging the slide to hold the same, and bolt mechanism having connection with the slide.

9. In a lock, the combination of an actuated lock-plate, a slide movable relatively thereto and held thereby when the lock-plate is in a certain position, the lock-plate moving from said position to release the slide, and bolt mechanism having connection with the slide.

10. In a permutation-lock, the combination of a vertically-movable lock-plate, tumblers normally sustaining the same, means for actuating the tumblers to release the lock-plate, a slide movable relatively to the lock-plate, the slide being held by the lock-plate when the lock-plate is in raised position, and bolt mechanism having connection with the slide.

11. In a lock, the combination of a bolt, a swinging member having a tangential slot therein, the slot receiving a portion of the bolt to impart movement to the bolt, a slide having a pin engaging said member to move the same, and a pinion meshing with rack-teeth on the slide, whereby to drive the slide.

12. The combination with two doors closing the one against the other, of bolts mounted in each door, the meeting edges of the doors having each a bolt, which bolts oppose each other, and the bolts of the first door being arranged so that the bolt at the meeting edge thereof will move outward when the other bolts of the said first door move inward, means for operating the bolts of the said first door, and permutation-lock mechanism for operating the bolts of the second door.

13. The combination with a door having permutation-lock mechanism inclosed therein, of a block serving to cover said mechanism and removably seated in a rear portion of the door, and an orificed disk mounted to turn in the rear portion of the door, the disk in one position serving to hold the block and in the other position serving to permit the removal thereof.

14. The combination with a door having permutation-lock mechanism inclosed therein, of a member removably seated in a rear portion of the door and serving to cover the lock mechanism, and a locking disk or member mounted to turn in the rear portion of the door and serving to removably hold the first-named member in place.

15. The combination with a main portion or support, of a door mounted thereon, a disk mounted to turn on the door and having a keyhole-slot therein, and a headed pin carried by the main portion or support and engaging in the keyhole-slot to hold the door in closed position until the disk is turned to disengage the pin from the walls of the keyhole-slot.

16. The combination with a door having lock mechanism inclosed therein, of an auxiliary door mounted on the main door and covering the lock mechanism, a disk mounted to turn in the auxiliary door and having a keyhole-slot therein, and a headed pin carried on the main door and engaging the walls of the keyhole-slot to hold the auxiliary door closed.

17. The combination with a door having permutation-lock mechanism inclosed therein, of an auxiliary door mounted on the main door, a disk mounted to turn on the auxiliary door, a pin carried by the main door and engaged by the disk, the pin serving to hold the auxiliary door closed, the disk being capable of disengaging the pin by a turning movement of the disk, and a spring-pressed pin carried in the main door and removably engaging the disk to prevent the turning thereof, the said spring-pressed pin coacting with parts of the permutation-lock, thus preventing the releasing movement of said pin except when the lock is in a certain predetermined position.

18. The combination with a main portion or support, of a door mounted thereon, a member mounted to turn in the door, a latch pivotally mounted on the door and engaging the member to hold the same, and a cam-shaped detent mounted on the main portion or support and engaged by the latch when the door is thrown to closed position, whereby to move the latch from engagement with the disk.

19. The combination with a door having permutation-lock mechanism contained therein, of an auxiliary door mounted on the main door, and means for holding the auxiliary door closed, such means being controlled by the lock mechanism and being releasable only when the lock mechanism is in a certain predetermined position.

20. The combination with a door having permutation-lock mechanism contained therein, of an auxiliary door mounted on the main door, and two independently-operative devices for holding the auxiliary door closed, such devices coacting with the lock mechanism and each being operative only when the lock mechanism is in a certain predetermined position, the one of such auxiliary-door-holding devices being operative during the time that the other of such devices is inoperative.

21. The combination with a door having countersunk passages in the front walls thereof, of permutation-lock mechanism contained in the door, and finger-keys mounted in the passages of the door to actuate the lock mechanism, the finger-keys normally lying flush with the front surface of the door.

22. A permutation-lock, having tumblers each having two wards respectively projecting upward and downward, the upper ward being of a width reduced over that of the lower ward, and the lower ward being longer than the upper ward, and the tumblers also having two oppositely-projected fingers extending from the tumblers at the juncture of the wards thereof.

23. A permutation-lock having a tumbler constructed with two wards respectively projected upward and downward, the edges of the ward at one side of the tumbler being in alinement with each other, and the upper ward being of a width reduced over that of the lower ward, and the tumbler having two oppositely-projected fingers extending from the tumbler at the juncture of the wards thereof.

24. In a permutation-lock, the combination with a bolt and mechanism connected therewith for throwing the same, of means serving to control said mechanism for throwing the bolt, tumblers controlling said means, each tumbler having two wards respectively projected upward and downward, the upper ward being of a width reduced over that of the lower ward, and the lower ward being longer than the upper ward, and the tumblers having oppositely-projected fingers extended therefrom at the juncture of the wards, thus permitting the reversal of the tumblers, for the purpose specified, and finger-keys for actuating the tumblers.

25. A permutation-lock, the combination with bolt-actuating mechanism, of tumblers controlling such mechanism, each tumbler having its end portions formed alike to permit the reversal of the tumblers, finger-keys respectively arranged end to end with the tumblers reciprocal to actuate the same.

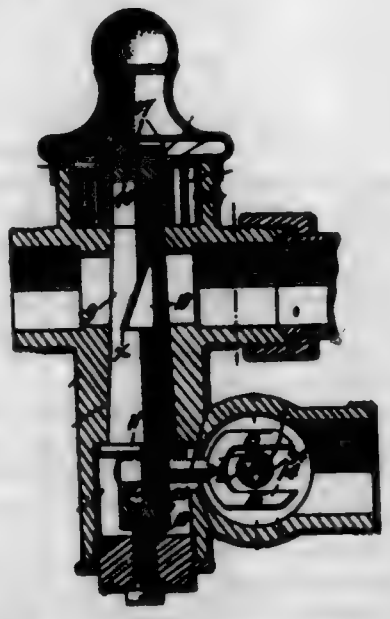
26. The combination with a door having lock mechanism, of an auxiliary door mounted on the main door to cover the lock mechanism, and means for holding the auxiliary door closed, such means being controlled by the lock mechanism.

27. In a permutation-lock, the combination of a lock-plate, tumblers controlling the lock-plate, a bolt, and means for throwing the bolt, such means being controlled by the lock-plate.

28. In a permutation-lock, the combination of tumblers, a lock-plate controlled by the tumblers, a bolt, and means for throwing the bolt, such means comprising a sliding member imparting movement to the bolt, the movement of the sliding member being controlled by the lock-plate.

29. In a permutation-lock, the combination of tumblers, a lock-plate controlled thereby, a bolt, and means for throwing the bolt, such means comprising relatively movable parts through which is transmitted the movement to throw the bolt, one of the parts being controlled by the lock-plate.

706,158. FLUID-PRESSURE-REGULATED GAS-VALVE. ADOLF BEILER, Pittsburg, Pa., assignor of two-fifths to Frederic Hartley, Pittsburg, Pa., and Charles H. Parsons, Sharon, Pa. Filed Jan. 31, 1902. Serial No. 92,080. (No model.)



Claim.—1. The combination of a gas-valve, a water-passage, a piston movable by the pressure of water against the same and having an opening to establish communication between the parts of the water-passage on opposite sides of the piston, a connection between the gas-valve

and the piston whereby they are movable simultaneously, and means coacting with the piston to progressively increase the flow of water through the opening therein as the piston moves in one direction, and to maintain pressure in the water-passage on the inner side of the piston when the latter is at the limit of its outstroke, substantially as described.

2. In a fluid-pressure-regulated valve of the class described, the combination of a casing or body having a gas-passage and a water-passage, a bore intersecting the gas-passage and communicating with the water-passage, a plug in said bore, said plug having an opening to permit a flow of gas through the gas-passage, and provided with an oscillating arm extending into the water-passage, a spring to turn the gas-plug in one direction, and a piston in the water-passage, said piston forming a valve to permit the flow of water through the water-passage, being movable in one direction by the pressure of the water on one side thereof, and coacting with the arm to turn the gas-plug against the tension of the spring, substantially as described.

3. In a fluid-pressure-regulated valve of the class described, the combination of a gas-valve, a water-passage, a piston, movable by the pressure of water against the same and having an opening to establish communication between the parts of the water-passage on opposite sides of the piston, a connection between the piston and the gas-valve, whereby the piston and gas-valve are movable simultaneously, and a fixed plug in the opening in the piston, said plug having a water-channel to maintain water-pressure in the water-passage on both sides of the piston, substantially as described.

4. In a fluid-pressure-regulated valve of the class described, the combination of gas-valve, a water-passage, a primary water-pressure regulator in said passage, a fixed plug carried by said primary water-pressure regulator, said plug having a channel of reduced capacity to establish communication between the parts of the water-passage on opposite sides of the primary water-pressure regulator, a piston movable by the pressure of water against the same and operating in the water-passage, said piston having an opening in which the plug extends, the latter partially closing said opening, and a connection between the piston and the gas-valve whereby the same are simultaneously operated, substantially as described.

5. The combination of a valve-case having a gas-passage, a water-passage, a chamber communicating with the latter, and a bore communicating with said chamber and the gas-passage, a gas-plug revolvable in said bore, said gas-plug extending across the gas-passage and having an opening for the purpose set forth, a piston in the water-passage, a connection between the same and the plug, a cap to close the outer side of the chamber and a bearing carried by said cap and engaging said plug to fit the latter in the bore, substantially as described.

6. In a fluid-pressure-regulated valve of the class described, the combination of a revolvable gas-plug having an arm, a spring to turn the plug in one direction, means to vary the tension of said spring, a piston movable by fluid-pressure in one direction and coacting with the arm to turn the plug against the tension of the spring and means to vary and predetermine the maximum pressure of fluid on said piston, substantially as described.

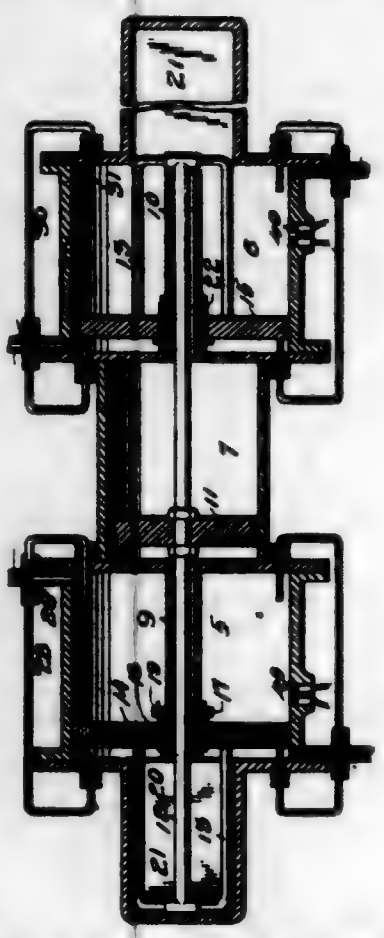
7. In a fluid-pressure-regulated valve of the class described, the combination of a gas-valve having an element to cause a progressively-increased flow of gas when moved in one direction, a spring to move said element in the reverse direction, a water-passage, a guide-plug therein, said plug having exterior water-channels of progressively-increased capacity in one direction, a piston, movable in the water-passage in one direction by the pressure of water, and having a bore in which the guide-plug is disposed, and a connection between the piston and the gas-valve, whereby the same are simultaneously operated, substantially as described.

8. In a fluid-pressure-regulated valve of the class described, the combination of a revolvable gas-plug, a coiled spring to turn said plug in one direction, the outer end of said spring being secured to a fixed point, a sleeve revolvable on said plug and to which the inner end of said spring is attached, means to lock said sleeve to said plug at any desired tension of said spring, and a fluid-pressure-actuated element connected to the plug to turn the latter in one direction against the tension of said spring, substantially as described.

9. A valve-case having a passage, in combination with a revolvable plug intersecting said passage, said plug having a transverse opening coincident with said passage and of progressively-diminishing width in the direction in which the plug is turned to cover said opening and cut off the passage, substantially as described.

10. The combination of a valve-case having a gas-passage, a water-passage, a chamber communicating with the latter, and a bore communicating with said chamber and the gas-passage, a gas-plug fitted and revolvable in said bore, said gas-plug extending across the gas-passage and having an opening for the purpose set forth, a piston in the water-passage, a connection between the same and the plug, and a revolvable closure in the outer side of said chamber, substantially as described.

706,154. PRESSURE-GENERATOR. GEORGE E. BLAKE, Greencastle, Ind. Filed Mar. 31, 1902. Serial No. 100,840. (No model.)



Claim.—1. In a device of the class specified, the combination with a plurality of alining cylinders, of a piston disposed in each cylinder, a piston-rod connected to all of the pistons, the central cylinder being in constant communication with the outer ends of the outer cylinders, valved openings arranged in the pistons of the outer cylinders, valved inlet and outlet pipes connected to opposite ends of the outer cylinder, and means for operating said valves.

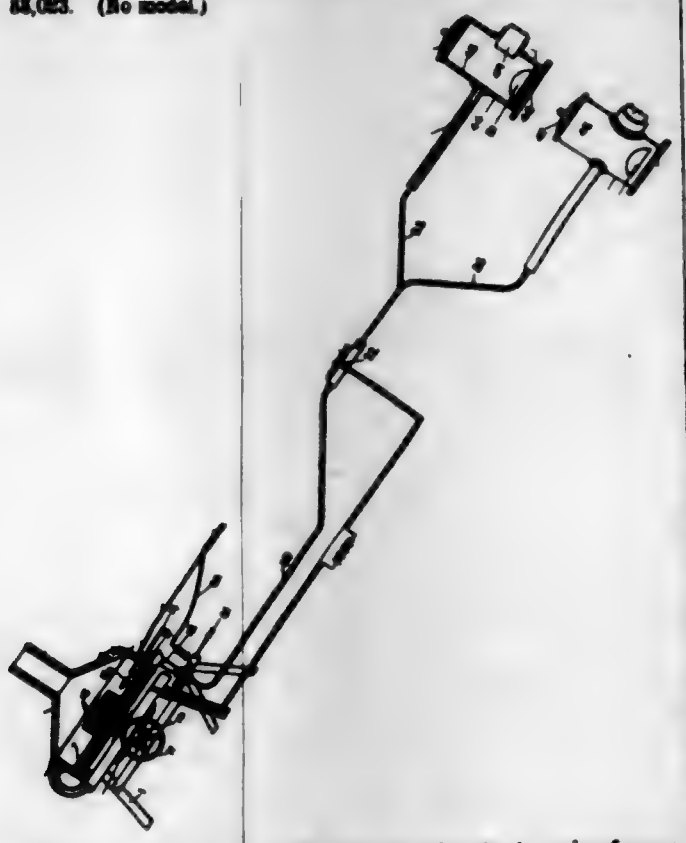
2. In a device of the class specified, the combination of the end cylinders, a central cylinder in constant communication with the outer ends of said end cylinders, valved pistons arranged in the end cylinders, a piston disposed in the central cylinder, a piston-rod connecting all three of the pistons for simultaneous movement, inlet and outlet pipes connected to the end cylinders, controlling-valves in said pipes, and means for operating said valves.

3. In a device of the class specified, the combination of the end cylinders having valved pistons, a centrally-disposed cylinder of a diameter less than that of the end cylinders, a piston arranged in the central cylinder, a piston-rod connecting all of the pistons for simultaneous movement, connecting-tubes extending through the end pistons and serving to keep the central cylinder in constant communication with the ends of the end cylinder, and piston-operated valves for governing the supply of explosive mixture to said end cylinders and the escape of exploded gases from all of the cylinders.

4. In a device of the class specified, the combination of the three alining cylinders, of which the centrally-disposed cylinder is of less diameter than the end cylinders, a piston in said central cylinder, tubes extending from the ends of the central cylinder to the end portions of the end cylinders, sliding sleeves loosely mounted on said tubes and having ports or passages for controlling the flow of gas from one end of the cylinder to the other, pistons mounted on said sleeves, a piston-rod extending from the central piston through both of the tubes, yokes connecting the ends of the piston-rods to the end pistons, cylinder-heads having slots for the reception of the yokes, inlet-pipes for the admission of an explosive mixture to the end cylinders, outlet-pipes for the escape of gas under pressure from all of the cylinders, valves in all of said pipes, and arms connected to said valves, and extending through the end walls of the cylinders into the path of movement of the end pistons.

5. In a device of the class specified, the combination with the three alining cylinders, of pistons in said cylinders, means for alternately supplying the end cylinders with an explosive mixture, means for permitting the escape of gas alternately from said cylinders, means for exploding the explosive mixture in said end cylinders, and means for alternately admitting portions of an exploded charge from the end cylinders to the central cylinder, thereby to assist in the movement of the pistons in the several cylinders.

706,155. RIVET HEATING AND DISTRIBUTING SYSTEM. VICTOR E. BROWNING, Cleveland, Ohio. Filed Jan. 2, 1902. Serial No. 88,023. (No model.)



Claim.—1. In a device of the character described, a pipe for conveying hot rivets that are in condition suitable for riveting, and means for creating a difference in fluid-pressure in said pipe on opposite sides of the rivet, so that it will be fed along in the pipe.

2. In a device of the character described, a pipe for conveying hot rivets that are in condition suitable for riveting, and a valve for admitting a fluid under pressure to said pipe behind the rivet to drive it through the pipe.

3. In a device of the character described, a pipe for conveying hot rivets that are in suitable condition for riveting, a valve through which a fluid under pressure may be admitted momentarily to the pipe behind the rivet and then cut off, so that the expansive force of the fluid may be utilized in driving the rivet, and means at the end of the pipe for receiving the rivet.

4. In a device of the character described, a main pipe for conveying hot rivets that are in condition suitable for riveting, means for creating a difference in fluid-pressure in said pipe on opposite sides of the rivet so that it will be fed through the pipe, a plurality of distributing-pipes connected with the main pipe, and a switch for directing the rivets from the main pipe into any distributing-pipe desired.

5. In a device of the character described, a main pipe for conveying rivets and like articles, means for creating a difference in fluid-pressure in said pipe on opposite sides of the rivet so that it will be fed through the pipe, a plurality of distributing-pipes connected with the main pipe, a switch for directing the rivets from the main pipe into any distributing-pipe desired, and receivers for the rivets adjustably connected with the distributing-pipes.

6. In a device of the character described, a pipe for conveying rivets by fluid-pressure, a valve for closing the pipe, an opening in the valve which may be brought into register with the pipe and through which a rivet may be inserted, connections with said valve whereby a fluid under pressure may be conducted thereto, and a port in the valve which is also adapted to be brought into register with the pipe so that the compressed fluid may enter to force the rivet through the pipe.

7. In a device of the character described, a main pipe which is adapted for conveying hot rivets and like articles, a plurality of branch distributing-pipes, a switch-box connecting the main and the branch pipes, a switch within said box, a spring for normally holding the switch so as to connect the main with one of the branch pipes, and electrical means for moving the switch to connect the main with another of the branch pipes.

8. In a device of the character described, a pipe through which rivets and like articles are adapted to be forced by fluid-pressure, and a receiver for the rivets connected with said pipe, said receiver having a tubular extension for telescoping the end of the pipe, and a block of resilient material mounted in the receiver opposite the extension, for the purpose specified.

9. In a device of the character described, a pipe through which rivets and like articles are adapted to be forced by fluid-pressure, and a receiver for the rivets connected with said pipe, said receiver having a tubular extension for telescoping the end of the pipe, a block of resilient material mounted in the receiver opposite the extension, for the purpose specified, and openings cut in the wall of the receiver near the bottom through which the rivets may be removed from the receiver.

10. In a system for heating and distributing rivets and like articles, a heating device, and means for conveying the rivets therefrom at a high speed and without detrimental cooling.

11. In a system for heating and distributing rivets and like articles, a furnace, means for conveying the rivets therefrom at a high speed and without detrimental cooling, and receivers connected with the conveying means into which the rivets are deposited.

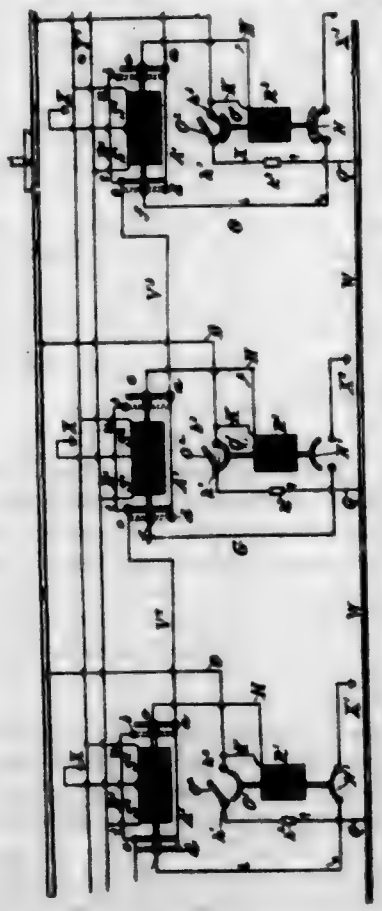
12. In a system for heating and distributing rivets and like articles, a furnace, a pipe for conveying the rivets therefrom at a high speed and without detrimental cooling, and means for creating a difference in fluid-pressure in said pipe on opposite sides of the rivet so that it will be fed through the pipe.

13. In a system for heating and distributing rivets and like articles, a furnace, means for conveying the rivets at a high speed and without detrimental cooling to an intermediate point, a plurality of conveying devices leading from said intermediate point, a switching device for connecting the conveying means with any one of the plurality of conveying devices desired, and receivers for the rivets connected with the conveying devices.

14. In a system for heating and distributing rivets and like articles, a pipe adapted for conveying the rivets, a valve for closing the entrance to the pipe, said valve having an opening which is normally out of register with the end of the pipe, a furnace for heating the rivets, &c., means for transferring the rivets from the furnace to the opening in the valve, means for rocking the valve to bring the opening into register with the pipe so that the rivet may enter therein, and means connected with the valve for admitting fluid under pressure to drive the rivet through the pipe.

15. In a device of the character described, a plurality of pipes through which rivets are forced by fluid-pressure, a single valve controlling the entrance to said pipes, a receiver in said valve for the rivets which is adapted to be brought into register with the end of any one of the pipes to drop the rivets therein, connections with said valve whereby fluid under pressure may be conducted thereto, and a port in the valve which may be brought into connection with any of the pipes at will to drive the rivets therethrough.

706,156. ELECTRIC RAILWAY. CHARLES R. CAMPBELL, New York, N. Y. Filed Dec. 28, 1900. Serial No. 41,322. (No model.)



Claim.—1. In a sectional third-rail electric railway, the combination, for sending electric cars in opposite directions over the same track, of the third-rail conductor, the main feed-wire carrying the working current, means for diverting an auxiliary or shunt therefrom having changeable groundings through means contacts, multiple switches and wiring adapted

and the piston whereby they are movable simultaneously, and means cooperating with the piston to progressively increase the flow of water through the opening therein as the piston moves in one direction, and to maintain pressure in the water-passage on the inner side of the piston when the latter is at the limit of its outstroke, substantially as described.

2. In a fluid-pressure-regulated valve of the class described, the combination of a casing or body having a gas-passage and a water-passage, a bore intersecting the gas-passage and communicating with the water-passage, a plug in said bore, said plug having an opening to permit a flow of gas through the gas-passage, and provided with an oscillating arm extending into the water-passage, a spring to turn the gas-plug in one direction, and a piston in the water-passage, said piston forming a valve to permit the flow of water through the water-passage, being movable in one direction by the pressure of the water on one side thereof, and cooperating with the arm to turn the gas-plug against the tension of the spring, substantially as described.

3. In a fluid-pressure-regulated valve of the class described, the combination of a gas-valve, a water-passage, a piston, movable by the pressure of water against the same and having an opening to establish communication between the parts of the water-passage on opposite sides of the piston, a connection between the piston and the gas-valve, whereby the piston and gas-valve are movable simultaneously, and a fixed plug in the opening in the piston, said plug having a water-channel to maintain water-pressure in the water-passage on both sides of the piston, substantially as described.

4. In a fluid-pressure-regulated valve of the class described, the combination of gas-valve, a water-passage, a primary water-pressure regulator in said passage, a fixed plug carried by said primary water-pressure regulator, said plug having a channel of reduced capacity to establish communication between the parts of the water-passage on opposite sides of the primary water-pressure regulator, a piston movable by the pressure of water against the same and operating in the water-passage, said piston having an opening in which the plug extends, the latter partially closing said opening, and a connection between the piston and the gas-valve whereby the same are simultaneously operated, substantially as described.

5. The combination of a valve-case having a gas-passage, a water-passage, a chamber communicating with the latter, and a bore communicating with said chamber and the gas-passage, a gas-plug revolubly in said bore, said gas-plug extending across the gas-passage and having an opening for the purpose set forth, a piston in the water-passage, a connection between the same and the plug, a cap to close the outer side of the chamber and a bearing carried by said cap and engaging said plug to fit the latter in the bore, substantially as described.

6. In a fluid-pressure-regulated valve of the class described, the combination of a revolubly gas-plug having an arm, a spring to turn the plug in one direction, means to vary the tension of said spring, a piston movable by fluid-pressure in one direction and coacting with the arm to turn the plug against the tension of the spring and means to vary and predetermine the maximum pressure of fluid on said piston, substantially as described.

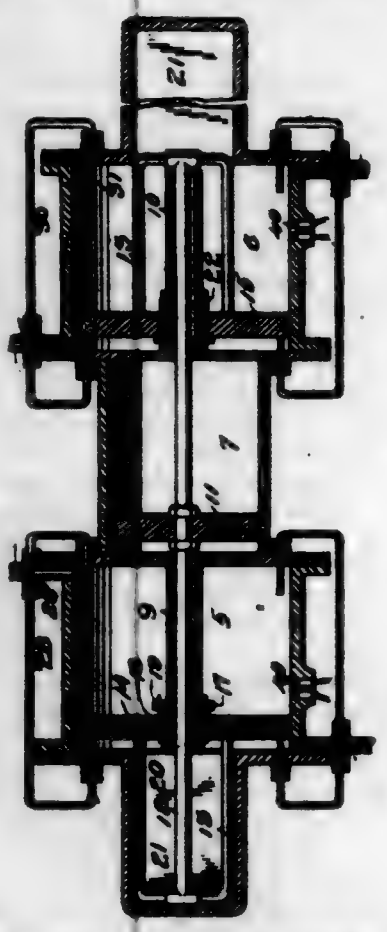
7. In a fluid-pressure-regulated valve of the class described, the combination of a gas-valve having an element to cause a progressively-increased flow of gas when moved in one direction, a spring to move said element in the reverse direction, a water-passage, a guide-plug therein, said plug having exterior water-channels of progressively-increased capacity in one direction, a piston, movable in the water-passage in one direction by the pressure of water, and having a bore in which the guide-plug is disposed, and a connection between the piston and the gas-valve, whereby the same are simultaneously operated, substantially as described.

8. In a fluid-pressure-regulated valve of the class described, the combination of a revolubly gas-plug, a coiled spring to turn said plug in one direction, the outer end of said spring being secured to a fixed point, a sleeve revolubly on said plug and to which the inner end of said spring is attached, means to lock said sleeve to said plug at any desired tension of said spring, and a fluid-pressure-actuated element connected to the plug to turn the latter in one direction against the tension of said spring, substantially as described.

9. A valve-case having a passage, in combination with a revolubly plug intersecting said passage, said plug having a transverse opening coincident with said passage and of progressively-diminishing width in the direction in which the plug is turned to cover said opening and cut off the passage, substantially as described.

10. The combination of a valve-case having a gas-passage, a water-passage, a chamber communicating with the latter, and a bore communicating with said chamber and the gas-passage, a gas-plug fitted and revolubly in said bore, said gas-plug extending across the gas-passage and having an opening for the purpose set forth, a piston in the water-passage, a connection between the same and the plug, and a revolubly closure in the outer side of said chamber, substantially as described.

706,154. PRESSURE-GENERATOR. George B. Blake, Greencastle, Ind. Filed Mar. 31, 1902. Serial No. 100,840. (No model.)



Claim.—1. In a device of the class specified, the combination with a plurality of alining cylinders, of a piston disposed in each cylinder, a piston-rod connected to all of the pistons, the central cylinder being in constant communication with the outer ends of the outer cylinders, valved openings arranged in the pistons of the outer cylinders, valved inlet and outlet pipes connected to opposite ends of the outer cylinder, and means for operating said valves.

2. In a device of the class specified, the combination of the end cylinders, a central cylinder in constant communication with the outer ends of said end cylinders, valved pistons arranged in the end cylinders, a piston disposed in the central cylinder, a piston-rod connecting all three of the pistons for simultaneous movement, inlet and outlet pipes connected to the end cylinders, controlling-valves in said pipes, and means for operating said valves.

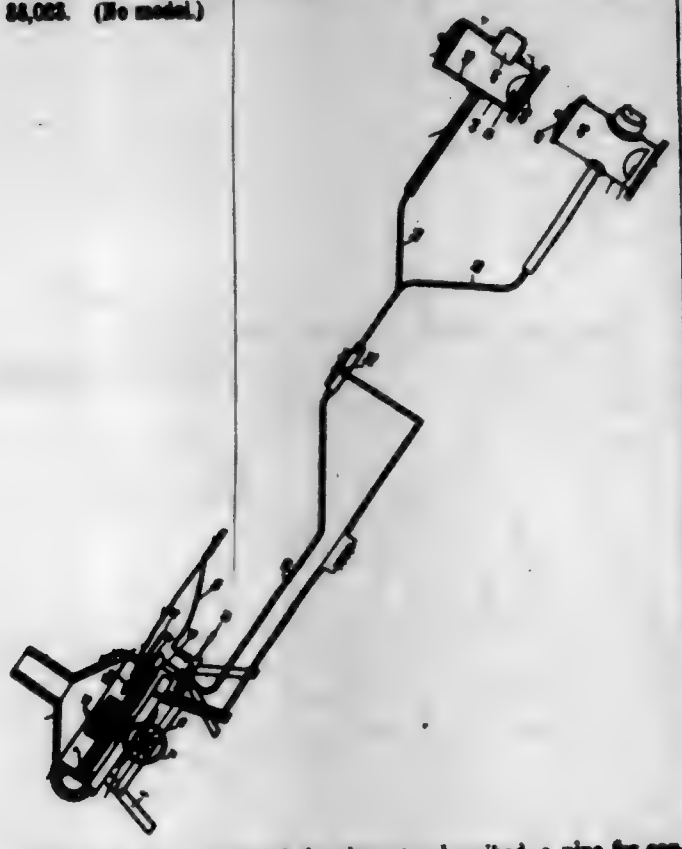
3. In a device of the class specified, the combination of the end cylinders having valved pistons, a centrally-disposed cylinder of a diameter less than that of the end cylinders, a piston arranged in the central cylinder, a piston-rod connecting all of the pistons for simultaneous movement, connecting-tubes extending through the end pistons and serving to keep the central cylinder in constant communication with the ends of the end cylinder, and piston-operated valves for governing the supply of explosive mixture to said end cylinders and the escape of exploded gases from all of the cylinders.

4. In a device of the class specified, the combination of the three alining cylinders, of which the centrally-disposed cylinder is of less diameter than the end cylinders, a piston in said central cylinder, tubes extending from the ends of the central cylinder to the end portions of the end cylinders, sliding sleeves loosely mounted on said tubes and having ports or passages for controlling the flow of gas from one end of the cylinder to the other, pistons mounted on said sleeves, a piston-rod extending from the central piston through both of the tubes, yokes connecting the ends of the piston-rods to the end pistons, cylinder-heads having slots for the reception of the yokes, inlet-pipes for the admission of an explosive mixture to the end cylinders, outlet-pipes for the escape of gas under pressure from all of the cylinders, valves in all of said pipes, and arms connected to said valves, and extending through the end walls of the cylinders into the path of movement of the end pistons.

5. In a device of the class specified, the combination with the three alining cylinders, of pistons in said cylinders, means for alternately supplying the end cylinders with an explosive mixture, means for permitting the escape of gas alternately from said cylinders, means for exploding the explosive mixture in said end cylinders, and means for alternately admitting portions of an exploded charge from the end cylinders to the central cylinder, thereby to assist in the movement of the pistons in the several cylinders.

706,155. RIVET HEATING AND DISTRIBUTING SYSTEM.

Victor E. Browning, Cleveland, Ohio. Filed Jan. 2, 1902. Serial No. 88,022. (No model.)



Claim.—1. In a device of the character described, a pipe for conveying hot rivets that are in condition suitable for riveting, and means for creating a difference in fluid-pressure in said pipe on opposite sides of the rivet, so that it will be fed along in the pipe.

2. In a device of the character described, a pipe for conveying hot rivets that are in condition suitable for riveting, and a valve for admitting a fluid under pressure to said pipe behind the rivet to drive it through the pipe.

3. In a device of the character described, a pipe for conveying hot rivets that are in suitable condition for riveting, a valve through which a fluid under pressure may be admitted momentarily to the pipe behind the rivet and then cut off, so that the expansive force of the fluid may be utilized in driving the rivet, and means at the end of the pipe for receiving the rivet.

4. In a device of the character described, a main pipe for conveying hot rivets that are in condition suitable for riveting, means for creating a difference in fluid-pressure in said pipe on opposite sides of the rivet so that it will be fed through the pipe, a plurality of distributing-pipes connected with the main pipe, and a switch for directing the rivets from the main pipe into any distributing-pipe desired.

5. In a device of the character described, a main pipe for conveying rivets and like articles, means for creating a difference in fluid-pressure in said pipe on opposite sides of the rivet so that it will be fed through the pipe, a plurality of distributing-pipes connected with the main pipe, a switch for directing the rivets from the main pipe into any distributing-pipe desired, and receivers for the rivets adjustably connected with the distributing-pipes.

6. In a device of the character described, a pipe for conveying rivets by fluid-pressure, a valve for closing the pipe, an opening in the valve which may be brought into register with the pipe and through which a rivet may be inserted, connections with said valve whereby a fluid under pressure may be conducted thereto, and a port in the valve which is also adapted to be brought into register with the pipe so that the compressed fluid may enter to force the rivet through the pipe.

7. In a device of the character described, a main pipe which is adapted for conveying hot rivets and like articles, a plurality of branch distributing-pipes, a switch-box connecting the main and the branch pipes, a switch within said box, a spring for normally holding the switch so as to connect the main with one of the branch pipes, and electrical means for moving the switch to connect the main with another of the branch pipes.

8. In a device of the character described, a pipe through which rivets and like articles are adapted to be forced by fluid-pressure, and a receiver for the rivets connected with said pipe, said receiver having a tubular extension for telescoping the end of the pipe, and a block of resilient material mounted in the receiver opposite the extension, for the purpose specified.

9. In a device of the character described, a pipe through which rivets and like articles are adapted to be forced by fluid-pressure, and a receiver for the rivets connected with said pipe, said receiver having a tubular extension for telescoping the end of the pipe, a block of resilient material mounted in the receiver opposite the extension, for the purpose specified, and openings cut in the wall of the receiver near the bottom through which the rivets may be removed from the receiver.

10. In a system for heating and distributing rivets and like articles, a heating device, and means for conveying the rivets therefrom at a high speed and without detrimental cooling.

11. In a system for heating and distributing rivets and like articles, a furnace, means for conveying the rivets therefrom at a high speed and without detrimental cooling, and receivers connected with the conveying means into which the rivets are deposited.

12. In a system for heating and distributing rivets and like articles, a furnace, a pipe for conveying the rivets therefrom at a high speed and without detrimental cooling, and means for creating a difference in fluid-pressure in said pipe on opposite sides of the rivet so that it will be fed through the pipe.

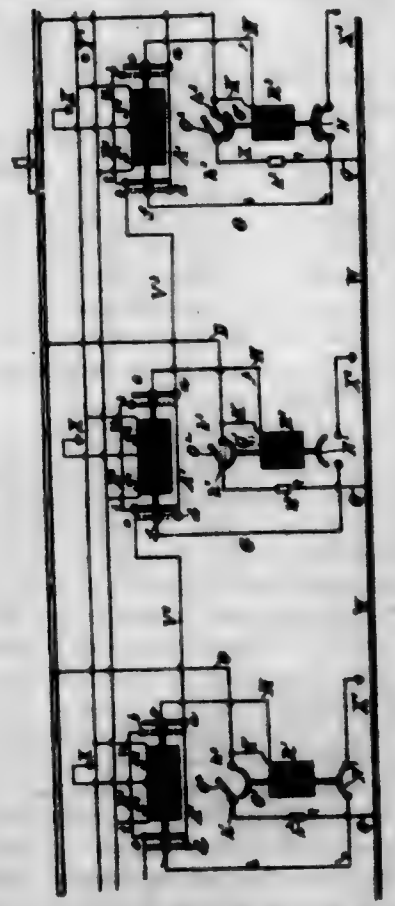
13. In a system for heating and distributing rivets and like articles, a furnace, means for conveying the rivets at a high speed and without detrimental cooling to an intermediate point, a plurality of conveying devices leading from said intermediate point, a switching device for connecting the conveying means with any one of the plurality of conveying devices desired, and receivers for the rivets connected with the conveying devices.

14. In a system for heating and distributing rivets and like articles, a pipe adapted for conveying the rivets, a valve for closing the entrance to the pipe, said valve having an opening which is normally out of register with the end of the pipe, a furnace for heating the rivets, &c., means for transferring the rivets from the furnace to the opening in the valve, means for rocking the valve to bring the opening into register with the pipe so that the rivet may enter therein, and means connected with the valve for admitting fluid under pressure to drive the rivet through the pipe.

15. In a device of the character described, a plurality of pipes through which rivets are forced by fluid-pressure, a single valve controlling the entrance to said pipes, a receiver in said valve for the rivets which is adapted to be brought into register with the end of any one of the pipes to drop the rivets therein, connections with said valve whereby fluid under pressure may be conducted thereto, and a port in the valve which may be brought into connection with any of the pipes at will to drive the rivets therethrough.

706,156. ELECTRIC RAILWAY.

Charles R. Campbell, New York, N. Y. Filed Dec. 28, 1900. Serial No. 41,228. (No model.)

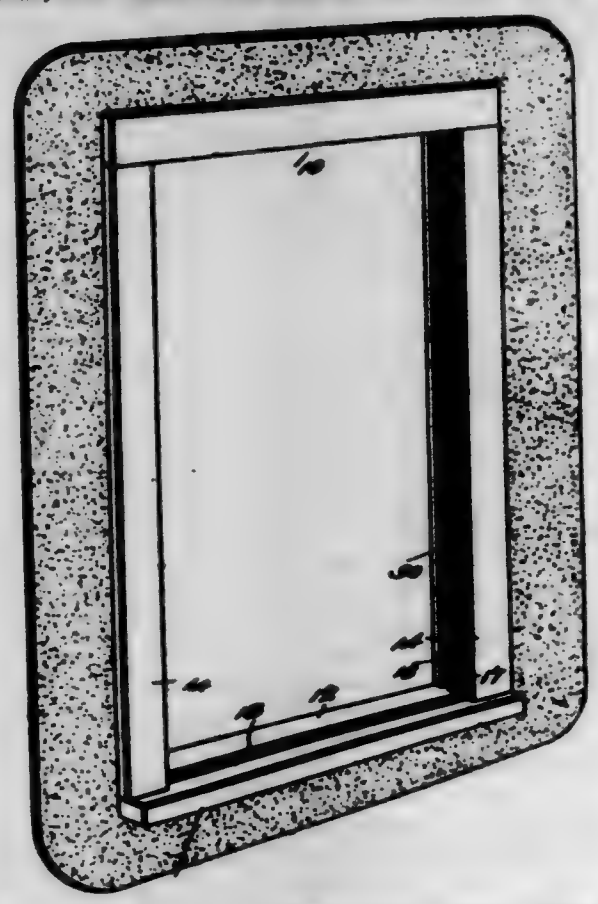


Claim.—1. In a sectional third-rail electric railway, the combination, for sending electric cars in opposite directions over the same track, of the third-rail conductor, the main feed-wire carrying the working current, means for diverting an auxiliary or shunt therefrom having changeable grounding through motor contacts, multiple switches and wiring adapted

to form separate pathways for grounding the auxiliary current in opposite directions, and supplementary wires carrying independent currents for actuating said switches.

2. In a sectional third-rail electric railway, the combination of the following instrumentalities, to wit: an electric feed-wire a sectional third-rail conductor, a series of single-acting solenoid coils or magnets, a series of double-acting solenoid coils or magnets, and suitable wires and switches connecting said coils to each other, to the feed-wire, and to the sections of said third rail, substantially in the manner and for the purpose herein described.

706,157. FRAME FOR DOORS OR WINDOWS. GEORGE CARR, Carrville, Iowa. Filed Jan. 10, 1902. Serial No. 89,662. (No model.)



Claim.—1. A frame for a building-opening, having a strip of paper surrounding, secured to and projecting outwardly beyond the frame, and a facing on the frame and bearing on the inner portion of the strip, the latter being secured between and projecting beyond the frame and casing, to close the joints between the facing, the studding and the siding, substantially as described.

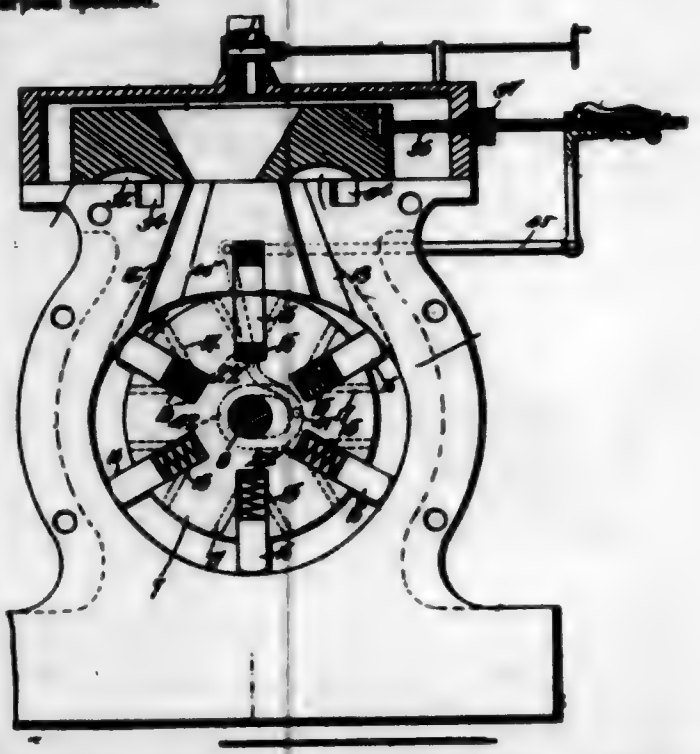
2. The combination with a building having an opening therein, of a frame in said opening having a strip of paper fastened between two of its members and extending outwardly therefrom and adapted to lie against the face of said building, said strip extending around and encircling said frame and projecting beyond the latter, and siding bearing on said projecting portion of the strip, the latter closing the joints between the facing, the studding and the siding.

706,158. ROTARY ENGINE. ALDEN P. CHARLES, Iola, Kans. Filed Feb. 24, 1902. Serial No. 95,622. (No model.)

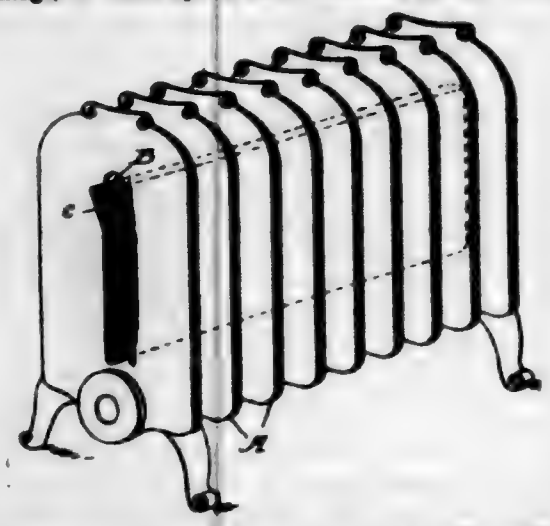
Claim.—1. In a rotary engine, the combination with the cylinder, of a revolvable piston having radially-disposed recesses and provided with angularly-disposed ports or passages leading from the periphery of the piston to the lower portion of each recesses, sectional abutments adapted to said recesses, said abutments each comprising a plurality of overlapping sections having recesses adjacent to the terminals of the ports or passages, substantially as specified.

2. In a device of the class specified, the combination with the cylinder, of a revolvable piston having radially-disposed recesses and provided with angularly-disposed ports or passages leading from the periphery of said piston to the lower portion of the recesses, abutments adapted to said recesses, each abutment comprising two sections or members having overlapping central portions and provided with recesses between adjacent to the terminals of said ports or passages, each section being furthermore provided with a closed port or passage extending in a diagonal line from the inner lower portion thereof.

3. In a device of the class specified, the combination with the cylinder, of a piston arranged within the cylinder and having its periphery eccentric with the curved inner wall of the cylinder between the inlet and exhaust port, that portion of the cylinder between the ports lying adjacent to the periphery of the cylinder, an abutment carried by the cylinder for contact with the periphery of the piston, a series of abutments adapted to radially-disposed recesses in said pistons, the piston being provided with angularly-disposed ports or passages leading from the periphery thereof to the lower portion of the recesses, each abutment comprising a plurality of members having overlapping central portions, and each member being provided with recesses adjacent to the terminals of the angular ports or passages, there being diagonally-disposed ports or openings arranged in each of said members, substantially as and for the purpose specified.



706,159. RADIATOR ATTACHMENT. GARDNER W. CHIPLEY, Chicago, Ill. Filed Apr. 14, 1902. Serial No. 103,063. (No model.)



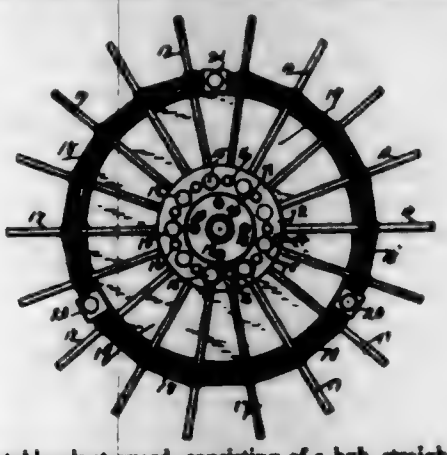
Claim.—A radiator attachment adapted to contain water and to be inserted in the usual openings between the columns of radiator-coils, said attachment comprising a narrow and deep water-receptacle, open at its top and made of thin sheet metal which is adapted to be distended against the sides of said openings by the weight of the column of water confined within said receptacle; substantially as described.

706,160. PLANT-GUARD ATTACHMENT FOR CULTIVATORS. MARTIN CHRISTIANSEN, Soda, Iowa. Filed Mar. 8, 1902. Serial No. 97,227. (No model.)

Claim.—1. A rotatable plant-guard consisting of a hub, straight spokes fixed to the hub to extend radially, a disk fixed to the inner end of the spoke and hub, and a rim fixed to the spokes at some distance from their outer ends, in combination with a bearer adapted to be fixed to the beams of a cultivator, to operate in the manner set forth, for the purposes stated.

2. A rotatable plant-guard, composed of a hub having an integral flange at one end, a disk fixed to said flange, a second disk placed against the end of the hub, a plurality of straight spokes provided with eyes at their inner ends, fixed between the two disks by means of rivets to extend radially and a band fixed to the outer end portions of the spokes, for the purposes stated.

3. A rotatable plant-guard, composed of a hub having an integral flange at one end, and a disk fixed to the said flange, a second disk placed against the end of the hub, a plurality of straight spokes provided with eyes at their inner ends fixed between the two disks, by means of rivets, to extend radially, and a band fixed to the outer portion of the spokes, and a disk detachably fastened to the spokes and rim, arranged and combined to operate in the manner set forth, for the purposes stated.

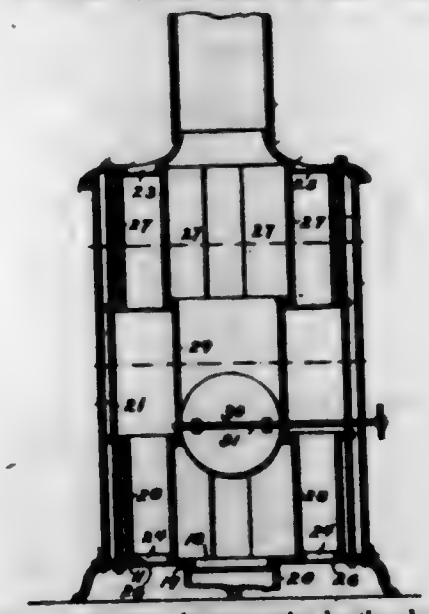


4. A rotatable plant-guard, consisting of a hub, straight spokes extending radially from the hub, a rim or band connecting the outer end portions of the spokes, clips fixed to the band, a disk connected with the said clips, and means for detachably fastening the disk to the spokes and rim, in combination with a bearer attached to a cultivator-beam, to operate in the manner set forth, for the purposes stated.

5. A plant-guard bearer, consisting of an upright, adapted to be detachably fastened to a cultivator-beam, a bar adapted to carry a rotatable plant-guard pivotally connected with the lower end of said upright to extend horizontally and to have an upward motion but no downward motion, and a weight adjustably connected with said bar, and a rotatable plant-guard attached to the front free end of said bar, arranged and combined to operate in the manner set forth, for the purposes stated.

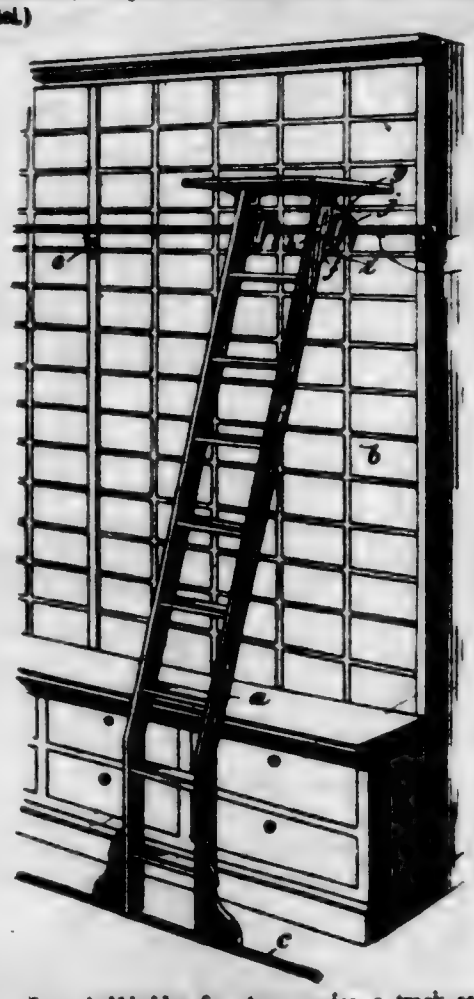
6. A plant-guard and ground pulverizer and distributer comprising a rotatable guard having spokes extending radially, a fixed band or rim fixed to the inner end portions of the rim, a disk detachably fastened to the spokes and said rim, an upright adapted to be fastened to a plow-beam, and its lower end doubled upward, a bar, elbow-shaped at its rear end, pivoted between the double part of said upright and its front end inclined laterally to support and carry the rotatable plant-guard, and a weight adjustably connected with said bar, arranged and combined to operate in the manner set forth, for the purposes stated.

706,161. **WARM-AIR RADIATOR.** JAMES CLEMENTS, East Chicago, Ind. Filed Mar. 18, 1901. Serial No. 51,704. (No model.)



Claim.—The combination, in a stovepipe heating-drum, of the upper and lower heads having peripherally-disposed flanges, a cylindrical shell having its upper and lower edges disposed within the peripheral flanges, the upper head being provided with a central opening the walls of which are outwardly flanged for the reception of an upper stovepipe-section, and the lower head being provided with a central opening having outwardly-flanged walls for the reception of a lower stovepipe-section and both heads being provided with an annular series of openings having inturned flanged walls, a removable section comprising a drum and a series of upper and lower flues rigidly secured at one end to said drum, the drum being of short vertical height and of a diameter less than the internal diameter of the shell and separated from said shell by an open annular interspace, a centrally-disposed annular smoke-flue 29 carried by the drum in alinement with the upper and lower smoke-pipe sections, the upper ends of the upper flues and the lower ends of the lower flues being removably fitted over the flanges of the openings in the upper and lower heads, and tie-bolts passing through the casing exterior of the drum and engaging with the upper and lower heads for clamping said heads against the shell and flues, substantially as specified.

706,162. **STORE-SERVICE LADDER.** AZRO A. COBURN, Holyoke, Mass., assignor to Coburn Trolley Track Manufacturing Company, Williamsett, Mass., a Corporation. Filed Sept. 30, 1901. Serial No. 77,061. (No model.)



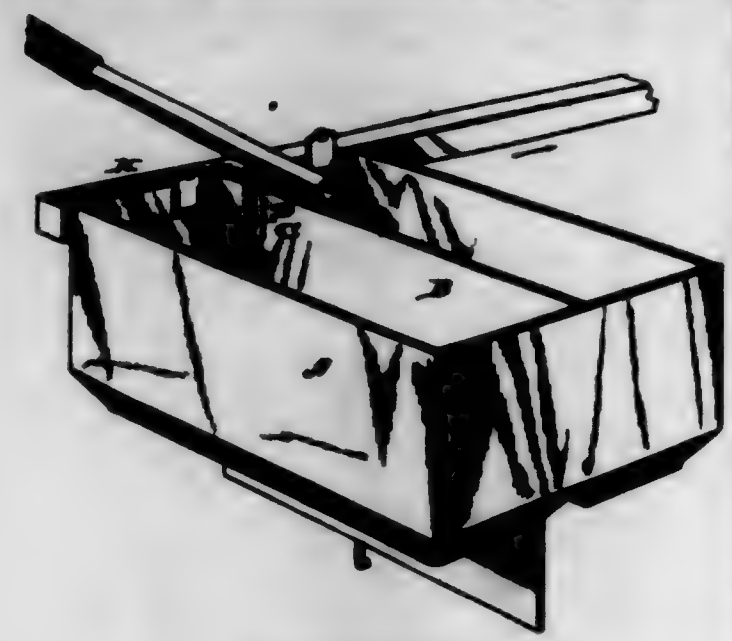
Claim.—In a shelf-ladder for store-service, a track secured to the floor, a roll on the lower end of the ladder engaging said track, a rail supported in front of and out of contact with the shelves, and near the upper end of the ladder, combined with a roller-supporting bracket fixed on the rear side of the ladder, a hook on said bracket extending from the upper end thereof rearwardly and downwardly to a point below said rail, a roller tapered from its center toward its ends, supported between projections, as *g*, *g*, on said brackets, whereby the central portion of said roller may bear on said rail.

706,168. **ORE-SEPARATING APPARATUS.** BEN C. COOK, Deadwood, S. D. Filed Jan. 13, 1901. Serial No. 43,779. (No model.)

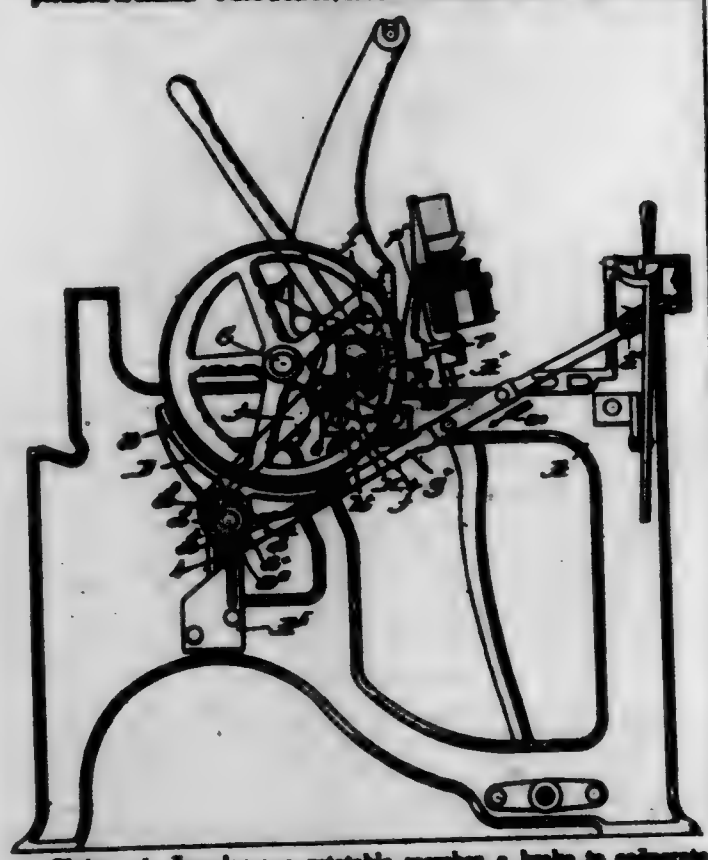
Claim.—1. An apparatus for separating ores comprising a box or receptacle with longitudinal partition-wall therein with the lower portion of each compartment thus formed hopper-shaped with the adjacent inclined walls diverging from and joined to the partition, bottoms hinged to the longitudinal edges of said hopper-shaped portions, a valved outlet from one compartment to the other at the top, and a feed-pipe disposed longitudinally of said box and supported thereon at one end to deliver the incoming material in a direction reverse to the outflow of said material from said box and a flexible connection with the said pipe beyond its point of support whereby the said pipe may be swung laterally while supported on the end of the box, said box having an overflow-discharge passage at the end over which the material is fed, the feed and overflow being opposite in direction, as set forth.

2. The herein-described apparatus for separating ores, consisting of the box or receptacle, a longitudinal partition therein with the lower portion of each compartment inclined downward and outward from the lower edge of said partition, bottoms hinged to the longitudinal edges of the said compartments, valved outlet from one compartment to the other, a chute-trough disposed at the end of the box away from the force and direction of the incoming product and independent valved openings from

the compartments to said trough, a feed-pipe resting on the top of the trough and extended at right angles to the length of the same, and a flexible connection with the end of the pipe beyond its support on the trough, said pipe being arranged to deliver the incoming product lengthwise of the box and in an opposite direction to the flow of the same from the box to the chute-trough, all substantially as and for the purpose specified.



706,164. STOPPING MECHANISM FOR LOOMS. Henry Ord, Woonsocket, R. I., assignor to Draper Company, Hopedale, Mass., a Corporation of Maine. Filed Dec. 23, 1901. Serial No. 86,594. (No model.)



Claim.—1. In a loom, a rotatable member, a brake to coöperate therewith, a fixed support for and relative to which the brake is movable circumferentially of and also toward and from said member, an eccentric connection between the brake and its support, and means acting by or through said connection to automatically set the brake, the compound movement thereof operating to wedge it against the rotatable member between the latter and the fixed support.

2. In a loom, a rotatable member, a brake to coöperate therewith, a fixed support for the brake, an eccentric connection between the latter and its support, and means to turn said connection to apply the brake.

3. In a loom, a rotatable member, a brake to coöperate therewith, a shiftable fulcrum on which the brake is mounted, the brake being interposed between the fulcrum and the rotatable member, and means to directly set upon and shift the fulcrum to thereby apply the brake to and stop rotation of said member.

4. In a loom, a rotatable member, a brake to coöperate therewith, a fixed support, a fulcrum for the brake, eccentrically mounted on said support, and means to turn the fulcrum on the support and thereby apply the brake.

5. In a loom, a normally rotating member, a brake to coöperate therewith, protector mechanism, a shiftable fulcrum for the brake, and direct connections between the said fulcrum and the protector mechanism, to shift the former and thereby set the brake by or through the operation of the latter.

6. In a loom, a rotatable member, a brake to coöperate therewith, a shiftable fulcrum for the brake, actuating means for and directly connected with said fulcrum and operated by or through the movement of the lay, the lay, and protector mechanism for the loom, to control the operation of said actuating means, the shifting of the fulcrum by the said means setting the brake.

7. In a loom, a normally rotatable member, a brake to coöperate therewith, the lay, a shipper, a fixed support, an eccentric connection between it and the brake, means operated by or through the lay to actuate said connection and set the brake, and means to release the shipper when said eccentric connection is actuated.

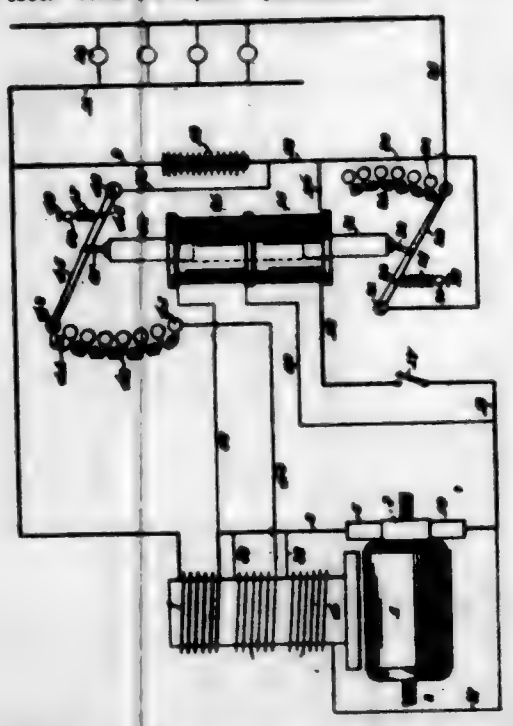
8. In a loom, a rotatable member, a brake to coöperate therewith, a shiftable fulcrum for the brake, means to automatically act directly upon and shift the fulcrum and thereby set the brake, and a manually-actuated device to operate through said means to release the brake.

9. In a loom, the lay, an actuating-shaft operatively connected therewith and having an annular member fast upon it, a brake to coöperate with said member, a fixed support, a fulcrum for the brake eccentrically mounted on said support, means operated by or through the movement of the lay to turn said fulcrum and thereby apply the brake, and protector mechanism for the loom, to control the operation of said means.

10. In a loom, the lay, actuating mechanism therefor, including a rotatable member, a brake to coöperate with said member, a shiftable fulcrum for the brake, and means, including a member mounted on the lay, to act directly upon and shift the fulcrum and thereby apply the brake on the forward beat of the lay.

11. In a loom, a normally rotating member, a brake to coöperate therewith, a shipper, a fixed support, a fulcrum for the brake, eccentrically mounted thereon, whereby rotative movement of the fulcrum applies or withdraws the brake, means operative upon improper bearing of the shuttle to actuate the fulcrum and set the brake, a connection between the fulcrum and shipper, to release the latter when the brake is applied, and manually-operated means to move said fulcrum to release the brake.

706,165. SYSTEM OF ELECTRICAL DISTRIBUTION FOR CAR-LIGHTING PURPOSES. John L. Greville, New York, N. Y. Filed Dec. 7, 1900. Serial No. 39,048. (No model.)



Claim.—1. In a system of electrical distribution the combination with a generator, a main circuit and electromagnetic means for controlling the magnetization of the generator, of a work-circuit and electromagnetic means for controlling the work-circuit, said last-mentioned electromagnetic means being adapted under predetermined conditions to act magnetically upon the first-mentioned electromagnetic means to cause the first-mentioned electromagnetic means to vary the magnetization of the generator.

2. The combination with a generator, storage battery and translating device, in electrical communication one with the other, of a field-coil, a

resistance device in circuit therewith, a yielding member coöperating with the resistance device, a second resistance device, and coöperating yielding member intersecting the translating-circuit, a pair of coaxially-disposed solenoids provided with separate cores, one core being operatively united to one of said yielding members and the other core to the other.

3. The combination with a generator, storage battery, and translating device, in electrical communication one with the other, as by usual mains, of a field-coil comprehending a yielding member and a resistance device, a solenoid having its windings in shunt with the generator-circuit and its core adapted to actuate said yielding member, a second solenoid having its windings in series with the generator, a variable resistance and coöperating yielding member intercepting the translating-circuit, the core of the second solenoid being operatively connected with said yielding member for the purpose specified, the two cores being separate.

4. The combination with a generator, storage battery and translating device in electrical communication one with the other, as by usual mains, of a field-circuit comprehending a yielding member and a resistance device, a solenoid having its windings in shunt with the generator-circuit and its core adapted to actuate said yielding member, a second solenoid coaxial with the first and having its windings opposed to that of the first and in series with the generator, a variable resistance and coöperating yielding member intercepting the translating-circuit, the core of the second solenoid being operatively connected with the yielding member for the purpose specified, the two cores being separate.

5. The combination with a generator, storage battery and translating device, in electrical communication one with the other through a switch adapted to close at a predetermined voltage, of a field-circuit comprehending a yielding member and a resistance device, a solenoid having its windings in shunt with the generator and its core adapted to actuate said yielding member, a second solenoid having its windings in series with the generator-circuit, a variable resistance and coöperating yielding member intercepting the translating-circuit, the core of the second solenoid being operatively connected with the said yielding member for the purpose specified, the two cores being separate.

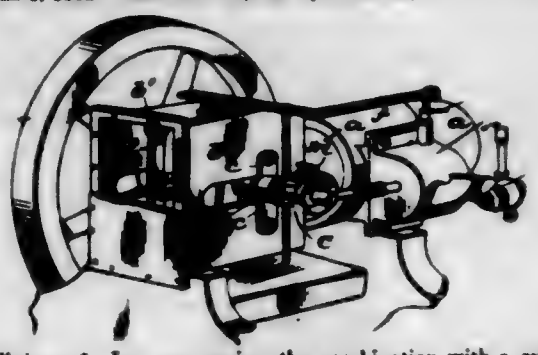
6. The combination with a generator, storage battery, and translating device, in electrical communication one with the other through a switch adapted to close at a predetermined voltage, of a field-circuit comprehending a yielding member and a resistance device, a solenoid having its windings in shunt with the generator-circuit and its core adapted to actuate said yielding member, a second solenoid coaxial with the first and having its windings opposed to that of the first and in series with the generator-circuit, a variable resistance and coöperating yielding member intercepting the translating-circuit, the core of the second solenoid being operatively connected with said yielding member for the purpose specified, and a field-coil in shunt with the generator-circuit, all coöperating substantially as and for the purpose specified, the two cores being separate.

706,166. GUIDE FOR SEWING EDGINGS. JONATHAN DAVIS, Phœnixville, Pa. Filed May 6, 1902. Serial No. 106,127. (No model.)

Claim.—1. In a machine for sewing loosely-taped edgings to garments, a means whereby during the sewing of the edging the loosely-looped tape or braid may be guided away from the needles of the machine, said means comprising two members, whereof one is secured to the presser-foot and is provided with an upwardly and forwardly projecting curled body portion having a lip extending over the feed-roller of the presser-foot and the other member is fixed to the bed-plate of the machine and is provided with an upwardly-projecting curled portion and an outwardly-flaring portion serving respectively as a guide for the edge of the looped tape and a guide for the inner portion of the edging.

2. In a machine of the character described, the combination of a presser-foot and its feed-roller, a needle or needles and means for operating the same, with a guide member having a base united to the presser-foot, an upwardly and forwardly projecting body portion extending upward adjacent to the needles and a curled lip portion extending over the feed-roller of the presser-foot and a second guide member fixed to the bed-plate of the machine in front of the first guide member and coöperating therewith.

706,167. GAS-ENGINE. THOMAS DOHERTY, Sarnia, Canada. Filed Jan. 3, 1902. Serial No. 88,294. (No model.)

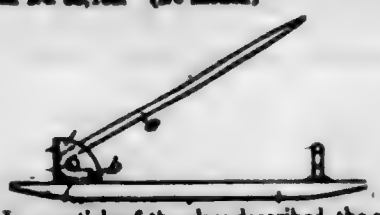


Claim.—1. In a gas-engine, the combination with a cylinder provided at one end with a crank-case, of two pistons adapted to operate within the cylinder, a double crank-shaft, one of said cranks being connected to one of the pistons by a single offset pitman, and the other crank connected to the other piston by a straight pitman and two offset connecting-rods, and means for supplying and exploding an explosive charge between the pistons.

2. In a gas-engine, the combination with a cylinder provided at one end with a crank-case, of a two-throw crank-shaft journaled in the walls of the crank-case, and two pistons, one of which is connected to one of the cranks by an offset pitman, and the other piston provided with a cross-bar which is connected to a cross-head by offset connecting-rods, said cross-head being connected to the crank by a straight pitman, substantially as specified.

3. In a gas-engine, the combination with a cylinder provided at one end with a crank-case, the other end of said cylinder being provided with oppositely-disposed guide-slots, and the inner wall of the crank-case provided with guide-grooves, of a two-throw crank-shaft journaled in the side walls of said crank-case, two pistons adapted to operate in the cylinder, one of said pistons being provided with a cross-bar adapted to reciprocate in the guide-grooves of the crank-case, the said cross-bar connected by offset rods to a cross-head adapted to reciprocate in the guide-slots in the end of the cylinder, said cross-head being connected to one of the cranks, and the other piston connected to the other crank by an offset pitman, whereby the force of the explosion between the pistons, moving them in opposite directions, is transmitted to the shaft.

706,168. PIN. GEORGE W. DOVER, Cranston, R. I., assignor to George W. Dover Company, a Corporation of Rhode Island. Filed Dec. 7, 1901. Serial No. 85,102. (No model.)



Claim.—1. In an article of the class described, the combination with a plate, of a housing secured thereto having side walls and an end and bottom wall, a pivot secured in the side walls crossing the space between the same, adjacent to the angle of the housing, and a pin comprising a shank portion having an entering end and a recurved pivoted end, the latter describing a curve of less than a half-circle, said curved end being confined between said pivot and the end and bottom walls of the housing, the extreme end thereof coacting with the bottom wall of the housing to limit the movement of the pin in one direction, and the major portion of the pin coacting with the end wall to limit the movement of the pin in an opposite direction.

2. In combination, a housing comprising side walls, and an end and bottom wall, a pin proper having its blunt end recurved, the latter describing a curve of less than a half-circle a pivot finding a bearing in the bail thereof, the end wall coacting with the pin to limit its pivotal movement in one direction and the bottom wall coacting therewith to limit its movement in the opposite direction, the pivoted end of the pin being retained in place by the proximity of the pivot to the side walls of said housing.

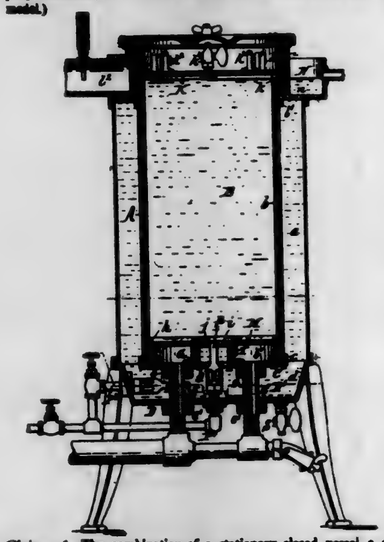
706,169. ANTISEPTIC TELEPHONE-MOUTHPIECE. WILLIAM H. ENGLISH and GEORGE A. ENGLE, San Francisco, Cal. Filed Oct. 28, 1901. Serial No. 80,522. (No model.)

Claim.—1. A telephone-mouthpiece consisting of an outer and inner shell having an intervening unfilled and unobstructed space, openings from said space through the inner shell, and means for discharging an antiseptic or sterilizing substance through said openings so that it may freely circulate throughout said space.

2. A telephone-mouthpiece consisting of outer and inner concentric

shells with an intervening unfilled and unobstructed space, a means for attaching the device to a transmitter, openings made through the interior shell connecting it with the interspace between the two, a receiving-opening formed in the outer shell, and a receptacle containing a sterilizing substance and connecting with substantially the lowest point of the space whereby the vapors enter the space and freely circulate therethrough and through the openings in the inner shell.

706,170. APPARATUS FOR HEATING OR COOLING LIQUIDS. HARVEY FIELDSHER, Littlehills, N. Y., assignor to D. H. Burrell & Company, Littlehills, N. Y. Filed Mar. 14, 1901. Serial No. 51,181. (No model.)



Claim.—1. The combination of a stationary closed vessel, a surrounding hollow jacket secured thereto, a hollow core detachably secured within said vessel and separated from the side walls thereof by an annular flow-space and from one end thereof by an outlet-chamber for the liquid to be treated extending across said vessel, an inlet-pipe for the liquid opening into the opposite end of said flow-space, a discharge-conduit for the liquid leading from said outlet-chamber, and means for supplying a heating or cooling medium to said jacket and core, substantially as set forth.

2. The combination of a stationary closed vessel, a surrounding hollow jacket secured thereto, a hollow core detachably secured within said vessel and separated from the side walls by an annular flow-space and from one end thereof by an outlet-chamber for the liquid to be treated extending across said vessel, said hollow core communicating with said hollow jacket, an inlet pipe for the liquid opening into the end of said vessel opposite to that at which said outlet-chamber is located, a discharge-conduit leading from said outlet-chamber, and means for supplying a heating or cooling medium to said jacket and core, substantially as set forth.

3. The combination of a stationary vessel, a surrounding hollow jacket, a stationary hollow core detachably secured within said vessel and separated from the side walls thereof by a flow-space for the liquid to be treated and from one end thereof by an outlet-chamber having an opening for the insertion and removal of said core, a detachable cover for said opening, a conduit for the discharge of the liquid which has been treated leading from said outlet-chamber, and means for supplying a heating or cooling medium to said jacket and core, substantially as set forth.

4. The combination of a stationary closed vessel, a surrounding hollow jacket secured thereto, a chamber at one end of said vessel extending across said vessel and said jacket, a stationary hollow core arranged within said vessel and separated from the side walls thereof by a flow-space for the liquid to be treated and from one end thereof by an outlet-chamber, a detachable hollow connection by which said core is attached to said vessel and placed in communication with said first-mentioned chamber, a supply-pipe for the liquid to be treated opening into the flow-space adjacent to said first-mentioned chamber, an outlet for the liquid which has been treated, and means for supplying a heating or cooling medium to said jacket or core, substantially as set forth.

5. The combination of a stationary closed vessel, a hollow surrounding jacket secured to the same, an end chamber which communicates with said jacket and extends across one end of said vessel, a stationary hollow core arranged within said vessel and separated from the side walls thereof by a flow-space for the liquid to be treated and from the other end of said vessel by an outlet-chamber, a detachable hollow connection by which said core is attached to said vessel and placed in communication with said end chamber, a supply-pipe for the liquid to be treated extending through said end chamber and opening into the flow-space adjacent thereto, an outlet for the liquid which has been treated, and means for supplying a heating or cooling medium to said jacket and core, substantially as set forth.

6. The combination of a stationary vessel, a hollow surrounding jacket secured to the same, an end chamber between one end of the jacket and the adjacent end of the vessel, a stationary hollow core arranged within said vessel and separated therefrom by a flow-space for the liquid to be treated, a detachable hollow connection by which said core is attached to said vessel and placed in communication with said chamber, a supply-pipe for the liquid to be treated opening into the flow-space adjacent to said end chamber, an outlet-chamber, an outlet-conduit for the liquid which has been treated communicating with said outlet-chamber, said vessel having at its end adjacent to said outlet-chamber an opening for inserting and removing the core, and a detachable cover for closing said opening, substantially as set forth.

7. The combination of a stationary vessel, a surrounding hollow jacket secured thereto, a bottom chamber between said jacket and said vessel, a hollow core arranged within said vessel and separated therefrom by a flow-space for the liquid to be treated, a detachable, hollow connection by which said core is attached to the bottom of said vessel and placed in communication with said chamber, a supply-pipe for the liquid to be treated arranged below the bottom of said vessel and opening into said flow-space at the lower end thereof, and an outlet-chamber at the upper end of said flow-space, substantially as set forth.

8. The combination of a stationary vessel, a surrounding hollow jacket secured thereto, a bottom chamber between said jacket and said vessel, a hollow core arranged within said vessel and separated therefrom by a flow-space for the liquid to be treated, a detachable hollow connection by which said core is attached to the bottom of said vessel and placed in communication with said bottom chamber, a supply-pipe for the liquid to be treated arranged below the bottom of said vessel and opening into said flow-space at the lower end thereof, and a drain device arranged in said liquid-supply pipe through which the contents of the vessel and core drain off upon disconnecting said core, substantially as set forth.

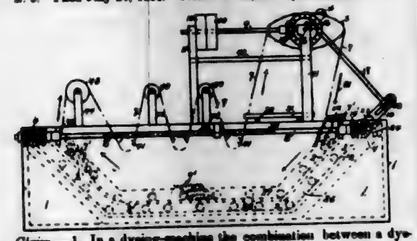
9. The combination of a stationary vessel, a surrounding hollow jacket secured thereto, an end chamber between the same and said vessel, a stationary hollow core arranged within said vessel and separated therefrom by a flow-space for the liquid to be treated, a detachable tubular connection between said vessel and said core, which establishes communication between the chamber and the core, a supply-pipe for the liquid to be treated discharging into said flow-space, and a supply-pipe for the heating medium discharging into said chamber in line with said tubular connection, substantially as set forth.

10. The combination of a stationary vessel, a surrounding hollow jacket secured thereto, an end chamber between the same and said vessel, a hollow core arranged within said vessel and separated therefrom by a flow-space for the liquid to be treated, a detachable tubular connection between said vessel and said core which establishes communication between the end chamber and the core, a supply-pipe for the liquid to be treated discharging into said flow-space, and a supply-pipe for the heating medium having branches discharging into said end chamber in line with said tubular connection and in line with said jacket, substantially as set forth.

11. The combination of a stationary vessel, a surrounding hollow jacket secured thereto, a bottom chamber between the same and said vessel, a stationary hollow core arranged within said vessel and separated from the side walls thereof by a flow-space for the liquid to be treated and from the upper end thereof by an outlet-chamber, a detachable, hollow connection by which said core is attached to the bottom of said vessel and placed in communication with said bottom chamber, a supply-pipe for the liquid to be treated opening into said flow-space at the lower end thereof, means for supplying a heating or cooling medium to said jacket and core, and an overflow-box arranged on the outer side of said vessel and communicating with the top of said jacket, substantially as set forth.

12. The combination of a stationary vessel, a surrounding hollow jacket secured thereto, a bottom chamber between said jacket and said vessel, a hollow core arranged within said vessel and separated from the side walls thereof by a flow-space for the liquid to be treated and from the upper end thereof by an outlet-chamber, a detachable hollow connection by which said core is attached to the bottom of said vessel and placed in communication with said bottom chamber, a supply-pipe for the liquid to be treated arranged below the bottom of said vessel and opening into said flow-space at the lower end thereof, and a vent-cock applied to the top of said core, substantially as set forth.

706,171. DYEING-MACHINE. WILLIAM H. PLETCHER, Paterson, N. J. Filed July 27, 1901. Serial No. 69,980. (No model.)

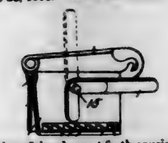


Claim.—1. In a dyeing-machine the combination between a dyeing-box an endless sliding rack, operated by sprockets and an actuating device of ratchet-wheels and levers, said racks sloping at each end of the box for the purpose of immersing and raising the goods, and the guides and guide-rollers for the rack, for the purpose of controlling said rack, and in connection with a succession of rollers for airing and drawing the goods from the liquid after being raised into position by the said sloping rack as set forth and described.

2. In a dyeing-machine the combination between the driving mechanism, consisting of the shaft 9, pulleys 10, the bevel-gearing 13 and 12 and the uprights 11 supporting the same and the reel, and a dye-box, endless rack, guides for the same actuated from the shaft on which the reel is, and the shaft 8 and gears 14 and 14' for operating the rack at the two ends of the tub as set forth and described.

3. In a dyeing-machine the combination between a shaft 9, a shaft 6 with an elliptic reel operated by said shaft 9, a lever 15 with a slot for lengthening and shortening the stroke, the rod 17 connecting the levers 15 and 19, the lever 19 also with a slot for the same purpose as that in lever 15, pawl 23, for operating the ratchet-wheel 25, pawl 24 for holding the same, the ratchet-wheel 25 secured to the shaft 20, the shaft 20 and the wheels on the same for moving the rack, the endless rack, guides and guide-rollers, and rollers 40 and 41 for oxidizing as set forth and described.

706,172. SKIRT-SUPPORTER. LLEWELLYN H. FLORY, Ashley, Pa. Filed June 20, 1901. Serial No. 65,206. (No model.)



Claim.—A device of the class set forth consisting of a doubled spring-metal plate forming two members, the rear member having outstanding teeth at the lower edge which are projectable through a slot at the lower edge of the front or outer member, a safety-pin attached to the upper edge of the said doubled plate, and means for clamping the outer member against the rear member.

706,173. FLUID-PRESSURE APPARATUS FOR WELL-DRILLING TOOLS. GEORGE B. GALLAGHER and CHARLES J. MAGENHEIM, St. Marys, Ohio. Filed July 17, 1901. Serial No. 68,054. (No model.)

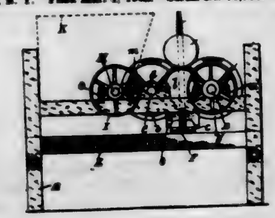
Claim.—1. A device of the character specified, comprising a fluid-containing cylinder, a piston mounted therein and operating to support the same by fluid contained between the piston and one end of the cylinder, valves for positively controlling passage of fluid from the upper to the under side of the piston to allow the cylinder to descend, a by-pass connecting the ends of the cylinder and a force-pump for withdrawing fluid from the under side of the piston and forcing it against the upper side thereof to raise the cylinder.

2. A device of the character specified comprising a fluid-containing cylinder having its ends closed by heads, a piston mounted within the cylinder and having a rod projecting through the upper head to be connected with suitable actuating mechanism, a force-pump carried by the lower head and coacting with a chamber arranged therein, a gravity-valve-controlled duct connecting the lower end of the cylinder and the chamber, a second chamber communicating with the first chamber through a gravity-valve-controlled duct, a by-pass connecting the cylinder-heads, branch ducts connecting the lower end of the cylinder and the said second chamber with the by-pass, and manually-operable valves arranged in the branch ducts and operating, respectively, to open or close communication between the lower end of the cylinder and the by-pass and between the said second chamber and the by-pass.

3. An apparatus of the character specified, comprising a cylinder to contain a fluid, a piston-carrying rod to work in the cylinder, a by-pass to establish direct communication between the ends of the cylinder, a duct to establish indirect communication between one end of the cylinder and the by-pass, a pump in communication with the duct for drawing fluid from the lower portion of the cylinder and forcing it through the by-pass to the top of the cylinder, and valves for controlling the passage through the by-pass and the duct.

4. An apparatus of the character specified, comprising a fluid-containing cylinder, heads secured thereto, a piston-carrying rod to work in the cylinder, the latter to be supported by the contained fluid, a by-pass pipe arranged exteriorly of and connecting the two cylinder-heads, valve-controlled chambers arranged in the lower cylinder-head, pumping means in cooperative relation with the chambers, a duct connecting the lower end of the cylinder with the chambers, a port having branches communicating, respectively, with the duct and one of the chambers and the by-pass and valves for controlling passage through the said branches.

706,174. DEVICE FOR QUARTERING FRUIT. JOHN GOSNER, Marion, N. Y. Filed Mar. 1, 1902. Serial No. 96,313. (No model.)



Claim.—1. A machine of the kind described, comprising a frame, a pair of parallel shafts on the frame, with connecting-gearing, a series of radial blades, a needle central with the blades and piercing the plane of said shafts between the latter, parts extending from the shafts to coact with the needle and disposed to act upon the fruit upon opposite sides of said needle, and means for revolving the shafts, substantially as set forth and shown.

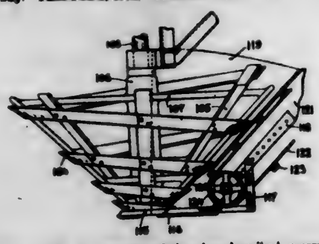
2. A machine for quartering fruit, comprising a frame, a pair of parallel shafts mounted for rotation in bearings on said frame, a needle supported by the frame for holding the fruit, a series of knives at the base of the needle, and means to act upon the fruit in proximity to the corners of the knives for moving the fruit along the needle and against the knives, substantially as and for the purpose specified.

3. A machine of the kind described, having a frame, a pair of parallel coacting oppositely-revolving shafts on the frame, a block or body on the frame having slots or narrow openings, knives in said openings in the block, and a needle held centrally in the block, and arms reaching out from said shafts to press upon the fruit upon opposite sides of said needle and to coact with said needle and the knives and to strike down in proximity to the corners of the knives, substantially as shown and described.

4. In a machine for quartering fruit and vegetables a block having vertical radial jaws and axial opening at their intersection, a pointed needle held in said opening, radially-disposed knives seated in slots in said jaws, shafts in parallel relation at right angles to said needle above the plane of the knives, means for imparting rapid or slow revolution to said shafts and beaters on said shafts to act downwardly upon the fruit on opposite sides of said needle, as and for the purpose specified.

5. In a machine for quartering fruit and vegetables, a block having vertical radial jaws and axial opening at their intersection, a pointed needle held in said opening, radially-disposed knives seated in the slots in said jaws, shafts in parallel relation to each other at right angles to said needle above the plane of the knives, means for imparting rapid or slow revolution to said shaft, a series of beaters disposed about each shaft and arranged to bear down against the fruit on said needle as the shafts are revolved and drive the fruit in succession against said blades, said beaters being formed at their outer edges with openings in line with said knives, all substantially as and for the purpose specified.

706,175. EXCAVATOR. OSCAR B. H. HAMMERMO, Christiania, Norway. Filed Feb. 3, 1902. Serial No. 92,362. (No model.)



Claim.—1. In an excavator of the class described, a screw digger consisting of a comparatively narrow cutter which winds in a spiral with more or less centrity around a vertical rotatable axle, and has a corresponding conical space between the said axle and cutter which receives the earth excavated by the cutter-blade, the earth falling down to the bottom of the screw, means for conveying the excavated material from the bottom of the screw to the surface of the field and a collecting-plate surrounding the rear of the screw and having an exit-opening for the dirt, substantially as set forth.

2. In an excavator substantially as set forth, the combination with the spiral cutter 104 and the collecting-plate 119 having a hole 120 of a transporter 122, 123 two plates 121 fixed to the collecting-plate between which the transporter runs, two horizontal transporting-bands 129, 130, receiving the earth from said transporter whereby the earth is conveyed out of the trench and heaped up at both sides thereof, substantially as described.

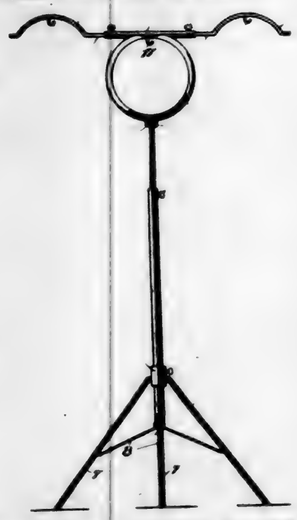
3. In an excavator as set forth the combination with the spiral cutter and the axle bearing the cutter of a shoe 115 which has a guide-bar 116 running along the center underneath the shoe being prolonged to the rear and prevented from tipping up by a curved piece 117, substantially as described.

4. In an excavator as set forth, the combination with the spiral blade of inclined placed bars 105 supporting said cutter, said bars being connected by means of arms 107 with a hub 106 keyed on the axle 108.

5. In a machine of the character described, the combination with the main frame 3, having supporting-wheels, of an inner frame 2, connected thereto by bolts and bearings, worm-wheel segments rigidly secured to said frame 2, vertical shafts having worms meshing with said worm-wheel segments, and means for operating said vertical shafts, substantially as described.

6. In a machine of the character described, the combination with the main frame 3, of a frame 2 mounted to tilt thereon, worm-wheel segments connected to said shaft, vertical shafts having worms meshing with said segments, a third frame supported by said second frame and vertically movable in relation thereto, means for moving said third frame vertically, and gearing carried by the third frame for operating said shafts, said gearing having splined connections with the shafts, substantially as described.

706,176. HORN-STAND. FRANK C. HAMETT, Kelso, Wash. Filed Dec. 31, 1901. Serial No. 87,926. (No model.)



Claim.—1. A horn-stand comprising a stem including extensible members, a ring removably engaged with the upper member of the stem, and arms removably and adjustably engaged with the ring, said ring and arms having horn-attaching means.

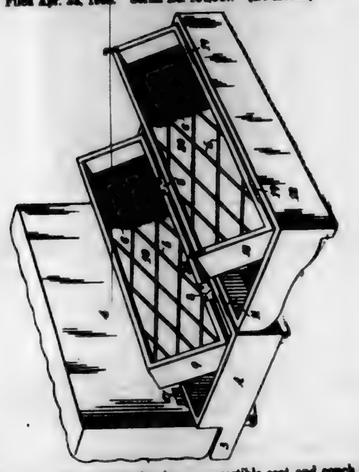
2. A horn-stand comprising a stem having a ring at its upper end having sockets, arms adjustably engaged with the sockets and means for holding the arms in their adjusted positions, said arms and ring having horn-attaching means.

3. A horn-stand comprising a stem having a threaded upper end, a ring removably engaged with the threads of the stem and having sockets at the upper portion thereof, arms having their inner ends adjustably engaged in the sockets and having upwardly-sprung arcuate outer ends, and means for holding the arms at different points of their adjustment, said arms and ring having horn-attaching means at the upper portions of their curvatures.

706,177. MEANS FOR TESTING THERMOSTATS. THOMAS M. HEAPHY, London, England. Filed Aug. 8, 1900. Serial No. 26,312. (No model.)

Claim.—In a fire-alarm system having a thermostat and its terminals in circuit with a source of electric current and a local alarm device, a heating resistance in proximity to the thermostat and in circuit with a source of electric current, one of the extremities of the said circuit being connected to a contact-point and the other extremity to a contact-piece on a movable switch-arm; a second insulated contact-piece on said switch-arm forming one extremity of a circuit including a source of electric current, a distant central-station alarm device and an automatic switch operated by the local alarm device; the other extremity of said circuit being connected to a terminal adapted for contact with the terminal on the switch-arm, whereby the thermostat and its alarm connections at the local station may be tested while allowing the alarms at the local and distant stations to operate simultaneously in case of fire, as set forth.

706,178. EXTENSION SEE-COUCH. JOHN HAGY, San Francisco, Cal. Filed Apr. 28, 1902. Serial No. 104,947. (No model.)



Claim.—1. The combination in a convertible seat and couch of a body portion, a back hinged to the rear to stand vertically or to be folded down horizontally upon the body portion, a section hinged to the front of the body and foldable therein and capable of being unfolded and extended outwardly from the front edge of the body, and a seat-section also hinged to the front edge of the body closable over the first-named section when folded into the body, said seat-section forming when unfolded a support for the inner upholstered section and having legs or supports upon its outer edge to rest upon the floor.

2. The combination in a convertible seat and couch of a hollow body portion, a section hinged to the front thereof so as to fold into the body or to be opened outwardly therefrom and having the side which forms the bottom when folded in composed of woven wire and cable-supports and an upholstered surface, a seat portion also hinged to the front and capable of being opened outwardly with its outer edge supported upon the floor or closed over the first-named section, said seat portion having its upper surface when closed formed of woven-wire supporting-cables and upholstery, and a back hinged to the rear of the body portion and normally supported in a vertical position when the seat portion is closed, said back having its rear portion upholstered and when the seat and inner section have been opened said back is turned down to rest upon the body portion with its upholstered back forming a continuation in the same plane with that of the unfolded inner section.

3. The combination in a convertible seat and couch of a body portion having a back hinged to its rear, said back having the rear portion upholstered to form the portion of a couch and turnable about its hinges so that it may rest upon the top of the body portion, a seat portion hinged to the front of the body having its upper surface, when closed, upholstered and arms which serve to support the back in its vertical position, said arms resting upon the floor and forming a support for the outer edge of the seat when unfolded, a couch-section hinged and foldable within the seat-section having an upholstered surface which forms the top when it is opened out from the seat-section and foldable legs by which its outer edge is supported, and a section hinged to the front edge of the body portion of the seat foldable therein and having an upholstered surface, said section being turnable about its hinges to open outwardly and rest upon the bottom of the inverted seat-section forming a continuation of the previously-opened section and intermediate between it and the upholstered surface of the back when the latter has been turned down into a horizontal position.

4. The combination in a convertible seat and couch of a hollow box or body portion having a seat-section hinged to its front adapted to open outwardly and having arms which support the outer edge when thus opened, said section having an upholstered seat-surface upon its upper side when in closed position, a second section hinged to the front of the body portion and foldable therein, said section having the side which is lowest when folded upholstered upon woven-wire and cable-supporting surface and adapted to be opened outwardly about its hinges to rest upon the inverted seat-section when opened and a back adapted to stand vertically when used as a seat and to be supported by the arms of the seat portion, said back having its rear portion upholstered and foldable to rest upon the body portion after the seat and inner section have been turned outwardly whereby the upholstered surface of the back and that of the inner folded section are brought into the same plane and their meeting contiguous edges forming an essentially continuous elastic couch-surface.

5. The combination in a convertible seat and couch, of a hollow body, a hollow section hinged to the front edge and having one side formed of elastic wire cables, a woven-wire fabric, and an upholstered surface thereon, said surface forming the bottom of the open section when folded into the body and the top when opened out, a hollow seat-section, hinged to the front of the body having a similarly-constructed seat-surface when closed, said section when opened outwardly, forming a support for the outwardly-opened interior section, and a back section hinged to the rear of the body, having its rear surface upholstered and turnable about its hinges after the seat and interior sections have been opened, so that it lies horizontally and its upholstered rear surface lies in plane with and contiguous to that of the interior section.

706,179. NUT-CRACKER. KATIE HOLDEN, Danville, Va. Filed May 16, 1902. Serial No. 107,669. (No model.)

Claim.—1. A nut-cracker consisting of a slotted nut-holder, in combination with a breaking-screw vertically adjustable in the slot of said holder.

2. In a nut-cracker, the combination with a nut-holder having a slot in its wall, a vertically-adjustable slide seated in said slot, a breaking-screw operable in said slide, and means for holding the slide against the pressure of the screw when operated to crack a nut.

3. In a nut-cracker, the combination with a nut-holder having a slot in its wall, a vertically-adjustable slide, seated in the slot, said slide being provided with flanges for engaging the inner and outer surfaces of the nut-holder, and a breaking-screw operable in said slide.

706,180. CALCULATING-MACHINE. IVAR HULTMAN, Stockholm, Sweden, assignor of one-half to Adolf Magnus Johnson, Stockholm, Sweden. Filed Dec. 16, 1901. Serial No. 86,102. (No model.)

Claim.—1. A calculating-machine, the combination of a series of driving-wheels fixed to a crank-axle, a series of controlling-wheels loosely mounted on another axle parallel to the crank-axle and adapted to engage

with movable teeth on the driving-wheels, a series of intermediate wheels loosely mounted on a third parallel axle and meshing with the controlling-wheels, and a series of carrying-wheels loosely mounted on a fourth parallel axle and adapted to engage with fixed teeth on the driving-wheels after having been turned a little by means of the intermediate wheels, said carrying-wheels acting upon the next controlling-wheel substantially as set forth.

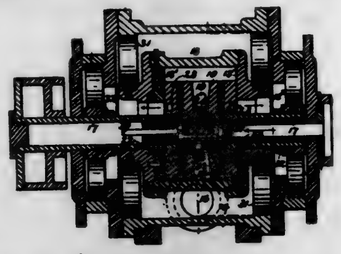
2. A calculating-machine having four series of wheels (viz. driving, controlling, intermediate and carrying wheels) on four parallel axles, two of which (viz. controlling and intermediate) are mounted in a movable carriage, the carrying-wheels having teeth disposed in groups separated by wide spaces, so that said wheels cannot be turned directly by the driving-wheels unless first acted upon indirectly by means of the intermediate wheels and thereby brought into working position.

3. A calculating-machine having four parallel series of wheels (called driving, controlling, intermediate and carrying wheels), the driving-wheels having two series of fixed teeth adapted to engage with the carrying-wheels, the last tooth in each series being enlarged in peripherical direction and preferably common to both series, substantially as and for the purpose set forth.

4. A calculating-machine consisting of driving-wheels with two series of fixed teeth and one series of movable teeth, controlling-wheels adapted to engage with said movable teeth when these are brought into working position, intermediate wheels meshing with said controlling-wheels, and carrying-wheels having teeth disposed in groups and provided with two tappets each having an arm for each group of teeth, the one tappet being acted upon by a tappet fixed to the corresponding intermediate wheel for bringing the carrying-wheel in working position, so that it may be acted upon by the fixed teeth of the corresponding driving-wheel and thus turned a distance corresponding to a group of teeth, whereby the other tappet is caused to act upon the next intermediate wheel or upon a wheel fixed to the same for performing the "carrying," said machine having means for stopping the movement of the wheels and for showing the result of the operation, substantially as and for the purpose specified.

5. A calculating-machine having driving-wheels provided with fixed teeth and movable teeth, the latter consisting of levers turnable in axial planes and acted upon by concentric ribs for bringing the same into or out of working position.

706,181. ROTARY MOTOR. CARL A. HULT and OSCAR W. HULT, Stockholm, Sweden. Filed Dec. 5, 1899. Serial No. 739,283. (No model.)

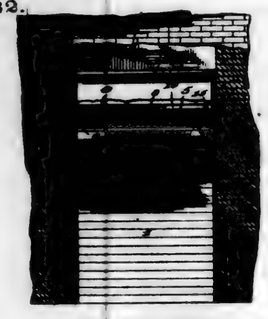


Claim.—In a rotary engine a piston provided with at least two vanes and an eccentric cone set in rotation by the said piston characterized by circular apertures arranged in the side pieces of the cone, concentrically to said cone, and surrounding the piston-shaft, said apertures being alternately passed by the ports, in the ends of the piston, of the admission and exhaust passages provided in the piston for the driving fluid.

706,182. HEAT-REGULATOR FOR FIREPLACES. ROBERT H. JOHNSON, Bremerton, Wash. Filed Apr. 24, 1902. Serial No. 104,546. (No model.)

Claim.—A fireplace having a throat or passage at its top communicating with an outlet-flue, a pivoted damper controlling said throat and normally inclined to throw the heat forward through the front of the fireplace, said damper consisting of longitudinally-adjustable plates, a stop limiting the closing movement of the damper, a shield carried by said stop and rearwardly curved for shielding the top of the fireplace from the heat passing out through the throat, a bracket fixed to one of the sides of the fireplace, an adjusting-rod connected to the bracket and sliding in the bracket and provided with a series of seats, and a spring-latch on the bracket to engage said seats, substantially as and for the purpose described.

706,182.



706,183. SEWING-AWL. ERASTUS H. JONES and ELI C. REPET, Pleasanton, Kans. Filed Jan. 23, 1902. Serial No. 90,965. (No model.)

Claim.—1. An awl comprising a casing having a chamber, a tension device having a fixed position upon the casing, a spool-holder within the chamber, and a spool mounted to rotate and to reciprocate longitudinally upon said holder as the thread is drawn out, whereby the unwinding portion of the thread is maintained substantially at right angles to or in alinement with the tension device, substantially as described.

2. An awl comprising a casing having a chamber, a tension device having a fixed position upon the casing, an elongated supporting-rod extending longitudinally within the casing, bearings in which said rod is removably mounted, and a spool having a bore through which the rod loosely extends, whereby the spool is free to rotate and reciprocate loosely on the rod as the thread is drawn out, substantially as set forth.

3. An awl comprising a chambered handle longitudinally divided to form two sections, means for uniting the sections in closed position, a tension device having a fixed position on one of the sections, a spool-support upon the other section, and a spool mounted to reciprocate and rotate upon said support, substantially as and for the purpose set forth.

4. An awl comprising a casing having a chamber, a tension-roller mounted in fixed bearings upon the casing, a spring exerting a resistance to the rotation of said roller, a spool-holder within the chamber, and a spool mounted to reciprocate and rotate upon the holder, the thread from the spool adapted to be drawn out over the roller, whereby the position of the thread relative to said roller will be maintained by the reciprocation of the spool, substantially as described.

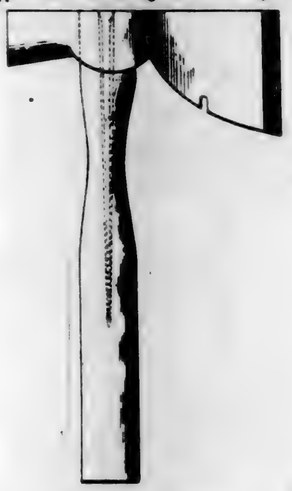
5. An awl comprising a chambered handle longitudinally divided to form two sections, said sections being provided at their forward ends with jaws to receive and clamp the needle, one of said jaws having a guide to receive and hold the other jaw, whereby the jaws are adapted to be connected and disconnected by an endwise sliding movement, fastening means for uniting the rear ends of the sections, a spool-holder within the handle, a spool removably mounted upon said holder, and a tension device for the thread passing from the spool, substantially as specified.

706,184. TOOL. JERRY H. KOCH, Alpha, W. Va. Filed May 1, 1902. Serial No. 105,485. (No model.)

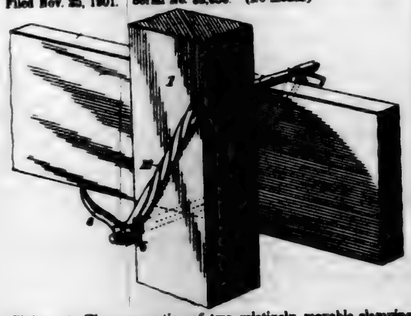
Claim.—1. A wedge for the purpose described, consisting of a body portion formed on its opposite sides with longitudinal ribs and upon its opposite edges with longitudinally-corrugated flanges, said flanges tapering from one end of the body portion to the other and merging into the ribs, substantially as set forth.

2. A wedge for the purpose described, consisting of a body portion formed on its opposite sides with longitudinal ribs and upon its opposite edges with longitudinally-corrugated flanges, said flanges tapering from one end of the body portion to the other and merging into the ribs, said body portion being provided at its opposite end with a driving-head, substantially as set forth.

3. The combination with a tool having an eye, and a handle having a bore, said handle being fitted in said eye, of a wedge for the purpose described, consisting of a body portion formed on its opposite sides with longitudinal ribs and upon its opposite edges with longitudinally-corrugated flanges, said flanges tapering from one end of the body portion to the other and merging into the ribs, said body portion being provided at its opposite end with a driving-head, substantially as set forth.



706,185. STAGING-CLAMP. JOHN LALLY, Waltham, Mass. Filed Nov. 25, 1901. Serial No. 83,636. (No model.)



Claim.—1. The combination of two relatively movable clamping members one of which is provided with a spiral biting edge, and means for forcing the spiral biting-edge portion of said member sidewise toward the oppositely-arranged portion of the other member.

2. The combination of two relatively movable clamping members one of which is twisted to form a spiral-like biting edge, and means for forcing the spiral biting-edge portion of said member sidewise toward the oppositely-arranged portion of the other member.

3. The combination of two relatively movable clamping members having interlocking terminal hooks, one of which members is provided with a spiral biting edge, and means for forcing the spiral biting edge of said member sidewise toward the oppositely-arranged portion of the other member.

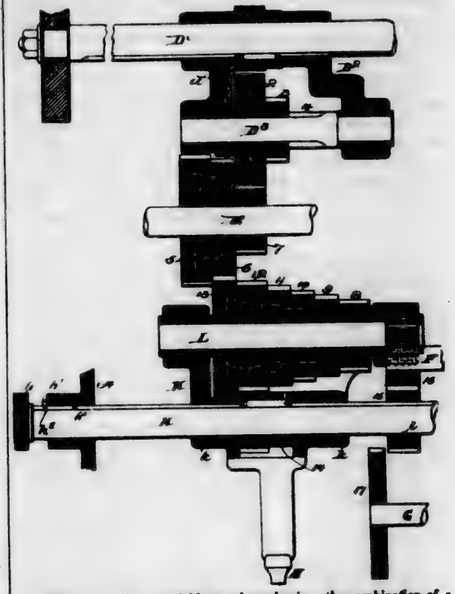
4. In a staging-clamp, two relatively movable members having interlocking terminal hooks one of which is provided with a wedge face, one of said members being provided with a spiral biting edge, and means for forcing the members into clamping position.

5. In a staging-clamp, two relatively adjustable members adapted to engage a pole or standard and one of which is provided with a keeper, in combination with a ledger-holder separable from both of said members and having means for engaging said keeper.

6. The combination with a pair of staging-clamps, of one or more ledger-holders separable therefrom and extending between the staging-clamps.

7. The combination with a pair of staging-clamps, of one or more ledger-holders extending between the staging-clamps and detachably connected therewith each holder carrying a clamping element.

706,186. VARIABLE-SPEED MECHANISM. RICHARD K. LE BLOND, Cincinnati, Ohio. Filed May 13, 1902. Serial No. 107,108. (No model.)



Claim.—1. In a variable-speed mechanism, the combination of a primary shaft, a transmitting-shaft, and a train of speed-changing gearing connecting said shafts, said gearing comprising an intermediate cone of gears, a swinging primary cone of gears between the primary shaft and the intermediate cone of gears, and a swinging transmitting cone of gears between the transmitting-shaft and the said intermediate cone of gears.

2. In a variable-speed mechanism, the combination of a primary shaft, a yoke mounted upon said shaft and carrying a primary cone of gears, a transmitting-shaft, a yoke mounted upon said transmitting-shaft and carrying a transmitting cone of gears, gearing connection between the primary shaft and the primary cone of gears, and between the transmitting-shaft and transmitting cone of gears, an intermediate shaft disposed between the primary and transmitting cones of gears, and a cone of gears carried by said intermediate shaft and adapted to be engaged by both the primary and transmitting cone of gears.

3. In a feeding mechanism for lathes, the combination of a primary shaft, a transmitting-shaft, and a train of speed-changing gearing connecting said shafts, said gearing comprising an intermediate cone of gears, a primary cone of gears between the primary shaft and the intermediate cone of gears, and a transmitting cone of gears between the transmitting-shaft and the said intermediate cone of gears, a lead-screw and gearing connections between said lead-screw and the transmitting-shaft.

4. In a feeding mechanism for lathes, the combination of a primary shaft, a transmitting-shaft, and a train of speed-changing gearing connecting said shafts, said gearing comprising an intermediate cone of gears, a primary cone of gears between the primary shaft and the intermediate cone of gears, and a transmitting cone of gears between the transmitting-shaft and the said intermediate cone of gears, a lead-screw, a feed-rod, and means for operatively connecting either the lead-screw or feed-rod to said transmitting-shaft.

5. In a variable-speed mechanism, the combination of a primary shaft, means for operating said shaft, a yoke mounted to swing upon said shaft and carrying a primary cone of gears, a transmitting-shaft, a yoke mounted to swing upon said shaft and carrying a transmitting cone of gears, an intermediate shaft carrying a cone of gears disposed between the primary and transmitting cones of gears and in engagement therewith, each of said yokes being provided with a handle disposed in convenient relation to each other to afford a ready and convenient means for changing the relation of both the primary and intermediate cones of gears with respect to the intermediate cone of gears.

6. In a variable-speed mechanism, the combination of a primary shaft, a yoke, the arms of which are hung upon said shaft, a gear splined to said shaft between the arms of the yoke, a primary cone of gears car-

ried by said yoke and in operative engagement with said gear, a transmitting-shaft, a yoke, the arms of which are hung upon said transmitting-shaft, a gear splined to said shaft between the arms of the yoke, a transmitting cone of gears carried by said last-named yoke and in operative engagement with said gear, an intermediate shaft and a cone of gears carried by said intermediate shaft and in operative engagement with both the primary and transmitting cone of gears.

7. In a variable-speed mechanism, the combination of a primary shaft, a transmitting-shaft, a yoke hung to each of said shafts and movable thereon, each of said yokes carrying a cone of gears, a shaft disposed intermediate said primary and transmitting shafts and carrying a cone of gears, said cones of gears being similarly arranged and disposed so that the largest gear of the primary and transmitting cones of gears may be engaged with each of the gears on the intermediate shafts, and the largest gear of the cone of gears on the intermediate shaft may be engaged with each of the gears of the primary and transmitting cones of gears.

8. In a feeding mechanism for lathes, the combination of a primary shaft, a transmitting-shaft having a gear fixed thereto, a lead-screw and a feed-rod each provided with a gear, means for longitudinally moving the transmitting-shaft to engage and disengage the gear carried thereby with or from either the lead-screw or feed-rod gear, and speed-changing mechanism disposed between the primary and transmitting shafts and comprising a primary cone of gears, a transmitting cone of gears, and an intermediate cone of gears adapted to be engaged by both the primary and transmitting cone of gears to transmit variable speed from the primary to the transmitting shafts.

9. In variable-speed mechanism, the combination of a driving cone of gears and a transmitting cone of gears, separate rocking yokes on which said cones are mounted, an intermediate cone of gears between said driving and driven cones, all the cones arranged step-like with the largest gear of the respective cones at the same end of the cones, for selectively engaging the gears of the driving-cone and the gears of the driven cone with the gears of the intermediate cone, and means for securing said rocking cones in adjusted positions.

10. In variable-speed mechanism, the combination of a stationarily-positioned cone of intermediate gears, a cone of driving-gears mounted on a rocking yoke selectively meshing therewith and imparting motion thereto, and a cone of driven gears mounted on a rocking yoke selectively meshing therewith and receiving motion therefrom, and means for securing the rocking yokes in adjusted positions.

11. In variable-speed mechanism, the combination with a lathe-bed, of a stationarily-positioned cone of intermediate gears, a cone of driving-gears mounted on a rocking yoke meshing therewith and imparting motion thereto, a cone of driven gears mounted on a rocking yoke also meshing therewith and receiving motion therefrom, all the cones having gears arranged step-like with the largest gear of the respective cones at the same end of the cones, in the lathe-bed, and means for securing the rocking yokes in adjusted positions.

706,187. PUMPING APPARATUS. Tore G. R. Lundmark, Stockholm, Sweden, assignor, by mesne assignments, to De Laval Steam Turbine Company, a Corporation of New Jersey. Filed Jan. 17, 1900. Serial No. 1,518. (No model.)

Claim.—1. The combination of a steam-turbine, a pump actuated thereby, and means for continuously supplying feed under pressure to said pump; the aforesaid parts being constructed and arranged so that the said pump normally actuated by the said turbine at a speed too great to enable it through its own suction to raise liquid to a given height is enabled to do so by the supply of feed under pressure.

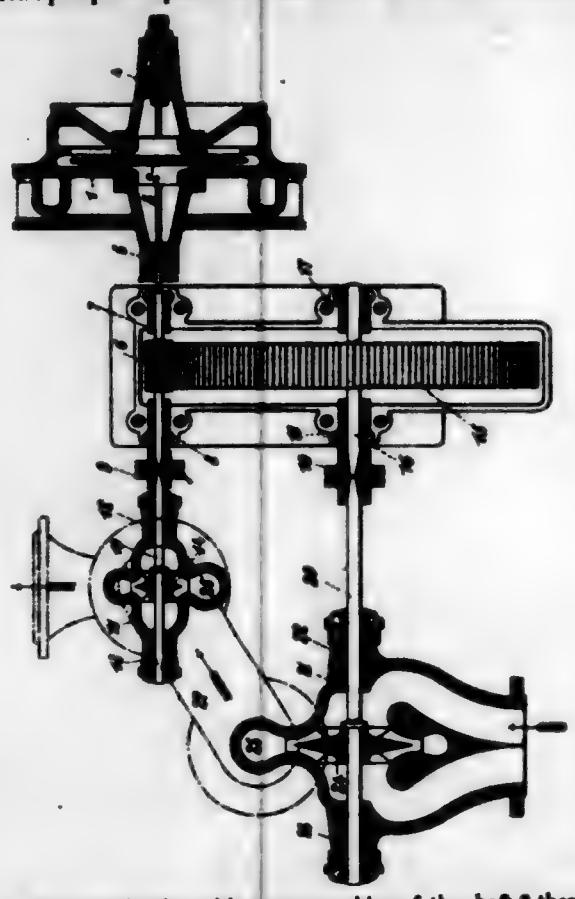
2. The combination of a steam-turbine, a rotary pump actuated thereby and means for continuously supplying feed under pressure to said pump, the aforesaid parts being constructed and arranged so that the said pump normally actuated by the said turbine at a speed too great to enable it through its own suction to raise liquid to a given height is enabled to do so by the supply of feed under pressure.

3. The combination of a steam-turbine, a rotary pump having its wheel on the shaft of said turbine, and a second pump constructed and arranged continuously to deliver feed to said first-named pump, as and for the purpose set forth.

4. The combination of a steam-turbine and two rotary pumps actuated thereby, one of said pumps being of high speed and small cubic capacity and the other of relatively low speed and large cubic capacity, and means whereby said second pump delivers liquid under pressure to said first pump.

5. The combination of a steam-turbine, a rotary pump having its wheel on the shaft of said turbine, a second rotary pump, speed-reducing gearing between the said turbine-shaft and the wheel of said second pump and a conduit connecting said pumps; whereby said second pump delivers feed under pressure to said first pump.

6. The combination of a steam-turbine, a rotary pump having its wheel on the shaft of said turbine, a gear on said shaft, a second rotary pump, a gear on the shaft of said second pump engaging with said first-named gear and a conduit connecting said pumps; the said second pump being arranged to deliver feed under pressure through said conduit to said first pump and the said gearing being constructed to actuate the shaft of said second pump at a speed less than that of the shaft of said first pump.



7. The combination with a steam-turbine of the shaft 3 thereof, gear 6 on said shaft, rotary pump 11 having wheel 14 on shaft 10, coupling 9 connecting shafts 3 and 10, shaft 16, gear 15 on said shaft engaging with gear 6, rotary pump 21 having wheel 24 on shaft 20, coupling 19 connecting shafts 16 and 20 and conduit 27 connecting pumps 11 and 21, substantially as described.

8. In combination with a pump of given dimensions of chamber and rate of speed and means for driving said pump, a second pump of greater dimensions of chamber and lower rate of speed constructed and arranged to deliver feed continuously to said first-named pump.

9. The combination of a steam-turbine, a rotary pump having its wheel on the shaft thereof and means for continuously supplying feed under pressure to said pump.

706,188. BOILER. Louis Mary and Polydore Baillik, Ghent, Belgium. Filed July 2, 1901. Serial No. 66,093. (No model.)

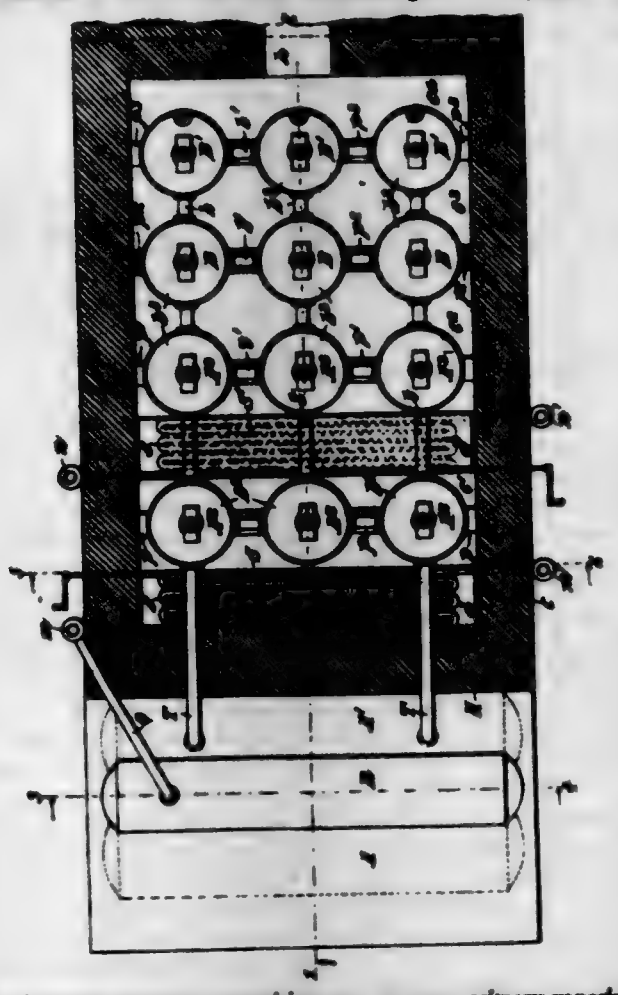
Claim.—1. A steam-generator comprising a furnace, a horizontal boiler above the furnace-grate, a series of auxiliary boilers and preheaters and means causing the products of combustion from the furnace to flow successively in opposite directions along opposite sides of each of the auxiliary boilers and preheaters, for the purpose set forth.

2. A steam-generator comprising a furnace, a horizontal boiler above the grate thereof, a steam-collector above said horizontal boiler, a series of auxiliary boilers and preheaters and means causing the products of combustion from the furnace to flow successively in opposite directions along opposite sides of each of said auxiliary boilers and preheaters; in combination with a superheater connected with the steam-collector and located in the path of the products of combustion, for the purposes set forth.

3. A steam-generator, comprising a furnace, a horizontal boiler above the grate thereof, a steam-collector above said boiler, a series of auxiliary boilers and preheaters and means causing the products of combustion to flow successively along opposite sides of each of said auxiliary boilers and preheaters; in combination with a superheater in the path of said products of combustion and connected with the steam-collector and means for diverting said products of combustion from said superheater, for the purpose set forth.

4. A steam-generator comprising one or more primary vaporizers in direct contact with a heating medium, a series of interconnected auxiliary vaporizers, a connection between a primary vaporizer and the first auxiliary vaporizer or vaporizers of a series of such, a series of interconn-

nected preheaters and a connection between the last auxiliary vaporizer or vaporizers of the series of each and the first preheater or preheaters of the series of each; in combination with means causing the aforesaid heating medium to flow successively along opposite sides of one or more auxiliary vaporizers and one or more preheaters, in a direction opposite to the direction of flow of the water therethrough, for the purpose set forth.



5. A steam-generator, comprising one or more primary vaporizers in direct contact with a heating medium, a series of vertical auxiliary vaporizing-drums interconnected at their upper ends at different levels, a connection from the higher level of the first auxiliary vaporizer or vaporizers of the series with a primary vaporizer, a series of vertical preheating-drums of less height than the auxiliary vaporizing-drums and connected together at or near their upper ends, and a connection between the last auxiliary vaporizer or vaporizers of the series and the upper end of the first preheater or preheaters of the series of such; in combination with means causing the aforesaid heating medium to flow successively along opposite sides of one or more auxiliary vaporizers and of one or more preheaters in a direction opposite to the flow of water therethrough, for the purpose set forth.

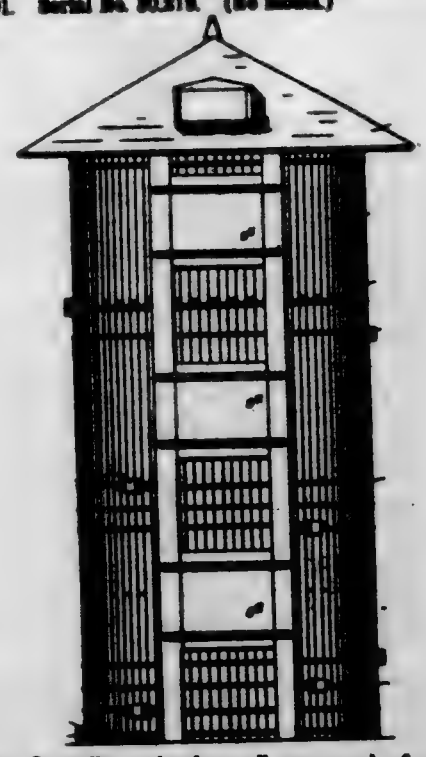
6. A steam-generator, comprising one or more primary vaporizers in direct contact with a heating medium, a steam-collector out of direct contact with the heating medium and connected to said vaporizer or vaporizers, a series of vertical auxiliary vaporizers connected together at their upper ends on different levels, a connection from the higher level of the first auxiliary vaporizer or vaporizers with a primary vaporizer, a series of vertical preheaters of less height than the auxiliary vaporizers and connected together at or near their upper ends, and a connection between the upper end of the last auxiliary vaporizer or vaporizers of the series and the like end of the first preheater or preheaters of the series; in combination with means causing the aforesaid heating medium to flow successively along opposite sides of one or more auxiliary vaporizers and one or more preheaters in a direction opposite to the flow of water therethrough, a superheater in the path of said medium and connected with the steam-collector and means for diverting the heating medium from said superheater, for the purpose set forth.

8. A steam-generator, comprising a furnace, two horizontal boilers above the furnace-grate, a chamber adjacent to and in communication with said furnace, a series of vertical boilers A^2 A^3 arranged in sets of three interconnected at their upper ends, a connection at a higher level between one of the horizontal boilers and two boilers A^2, vertical preheaters B, B', of less height than the auxiliary boilers and interconnected at their upper ends, and vertical staggered partitions between the boilers of each set and the chamber-walls to cause the products of combustion from the furnace to flow successively along opposite sides of each set of auxiliary boilers and preheaters in a direction opposite to the flow of water therethrough, for the purpose set forth.

9. A steam-generator, comprising a furnace, two horizontal boilers above the furnace-grate, a steam-collector above and connected with said boilers, a chamber adjacent to and in communication with said furnace, a series of vertical boilers A^2 A^3 arranged in sets of three interconnected near their upper ends, a connection at a higher level between one of the horizontal boilers and two boilers A^2, vertical preheaters B, B', of less height than the auxiliary boilers and interconnected at their upper ends, and vertical staggered partitions between the boilers of each set and the chamber-walls to cause the products of combustion from the furnace to flow successively along opposite sides of each set of auxiliary boilers and preheaters in a direction opposite to the flow of water therethrough; in combination with a superheater in the path of the products of combustion and connected with the steam-collector, for the purpose set forth.

10. A steam-generator, comprising a furnace, two horizontal boilers above the furnace-grate, a steam-collector above and connected with said boilers, a chamber adjacent to and in communication with said furnace, a series of vertical boilers A^2, A^3, arranged in sets of three interconnected near their upper ends, a connection at a higher level between one of the horizontal boilers and two boilers A^2, vertical preheaters B, B', of less height than the auxiliary boilers and interconnected at their upper ends, and vertical staggered partitions between the boilers of each set and the furnace-walls to cause the products of combustion from the furnace to flow successively along opposite sides of each set of auxiliary boilers and preheaters in a direction opposite to the flow of water therethrough; in combination with a superheater in the path of the products of combustion and connected with the steam-collector and means for diverting said products from said superheater, for the purpose set forth.

706,189. SILO. GEORGE W. MAHLOVE, Cleveland, Ohio. Filed Oct. 28, 1901. Serial No. 80,319. (No model.)



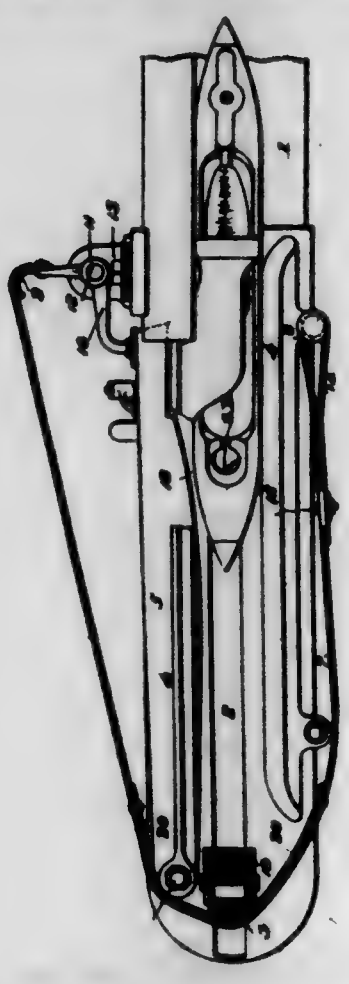
Claim.—1. In a silo, a circular wall composed of units formed of overlapping vertical members the edges whereof project outwardly from said wall, combined with encircling hoops which constrain said projecting edges inwardly, substantially as set forth.

2. In a silo, a circular wall composed of units formed of overlapping vertical members, the outermost of said members projecting outwardly from said wall, said wall presenting an uninterrupted cylindrical surface upon its inner side, combined with encircling hoops adapted to constrain inwardly the said projecting members, substantially as set forth.

3. In a silo, a circular wall made of two layers of material, and composed of units formed of overlapping vertical members, the free portions of the members of the outermost of said layers projecting outwardly from said wall, combined with encircling hoops constraining said free portions inwardly, substantially as set forth.

4. In a silo, a circular wall made of two layers of material, and composed of units formed of overlapping vertical members, the free portions of the outermost of said members projecting substantially tangentially from said wall, said wall presenting an uninterrupted cylindrical surface on its inner side, combined with encircling hoops constraining inwardly the said free portions, and means for adjusting the tension of said hoops, substantially as set forth.

706,190. SHUTTLE-LOCK FOR LOOMS. FRANCIS A. MILLS, Methuen, Mass., assignor of one-half to Grosvenor B. Simmons, Methuen, Mass. Filed Feb. 27, 1902. Serial No. 96,978. (No model.)



Claim.—1. A shuttle-box, a picker, a pivoted binder, a lever device pivoted on the box independent of the binder and a strap passing around the shuttle-box and having its ends connecting the lever device and the box in the manner for the purpose stated.

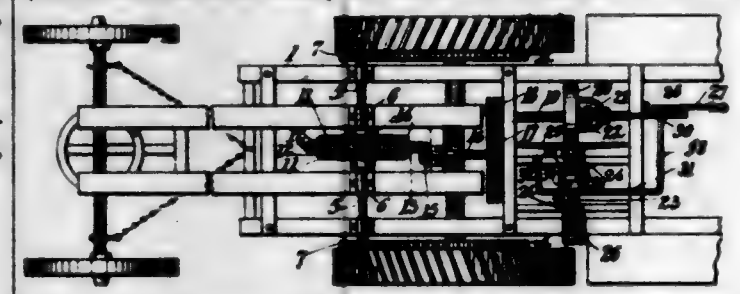
2. In a loom and in combination the shuttle-box, the picker, a pivoted binder for the box, a strap passing around the shuttle-box and fixed at one end to the box, and a lever device pivoted to the box at the free end of the binder, said lever device having an arm connected to the other end of the strap and an arm having a free bearing upon the free end of the binder, for the purpose stated.

3. A shuttle-box, a picker, a binder, a strap passing around and connected at one end to the lay, a device pivotally mounted on the lay connected to the other end of the strap and having an arm adapted to be forced with an impact pressure against the inner free end of the binder, whereby the strap receives and imparts the force of the impact of the shuttle to the said pivoted device and thence against the free end of the binder.

4. A shuttle-box, a picker, a binder, a strap connected at one end to the lay, a bell-crank lever mounted upon the lay having one arm connected to the other end of said strap, the other arm of said lever bearing on the free end of the binder and means for adjusting the length of the strap whereby to render effective the look of the binder upon the shuttle at any point of its throw in the box.

706,191. TRACTION-ENGINE. SAMUEL S. MORTON, WALTER S. MORTON, ROBERT L. MORTON, WILLIAM EVANS, and WILLIAM H. EVANS, York, Pa., assignors, by mesne assignments, to Morton Manufacturing Company. Filed Sept. 23, 1901. Serial No. 76,082. (No model.)

Claim.—1. The combination with a power-shaft and a driven shaft, the former having a longitudinal movement in its bearing, of a friction-wheel and a friction-disk, the one secured to the power-shaft and the other to the driven shaft, a collar fixedly secured to the power-shaft, a collar loosely secured to the power-shaft, and having antifriction-rollers arranged between them, a universally-movable lever, a link connecting the lever to the friction-wheel for moving it longitudinally upon its shaft across the face of the friction-disk, a pivoted lever adapted to engage the movable collar to force it toward the fixed collar, and a link between the pivoted lever and the universally-movable lever, substantially as set forth.



2. The combination with a two-part drive-shaft, the ends of which are arranged in close relation and are provided with beveled gears, a coupling-sleeve for connecting the ends of said shaft, a gear-wheel, the hub of which is loosely mounted upon said coupling-sleeve, and pinions journaled in said gear-wheel and in mesh with the gears carried by the shafts, substantially as set forth.

3. The combination with a two-part drive-shaft, the ends of which are arranged in close relation and are provided with annular grooves and with beveled gears, a split coupling-sleeve having annular inwardly-projecting flanges to engage said grooves, a gear-wheel, the hub of which is loosely mounted upon said coupling-sleeve to hold the same closed around the ends of the shafts, and pinions journaled in said gear-wheel and in mesh with the gears carried by the shafts, substantially as set forth.

4. In combination, gearing for the purpose described, comprising a power-shaft and a shaft to be driven, the one provided with a friction-disk and the other with a friction-wheel, and a universally-movable lever operatively connected to the disk and wheel and having an adjustment in one plane for independently adjusting the disk, an adjustment in a different plane for independently adjusting the wheel, and a third adjustment at an angle to said planes for simultaneously throwing the disk and wheel into frictional engagement and moving one across the face of the other, substantially as set forth.

706,192. WASHBOARD. SPENCER MCCAY, Topeka, Kans., assignor to Fred L. Woodbridge, Newark, Ohio. Filed Dec. 30, 1901. Serial No. 87,792. (No model.)

Claim.—1. In a washboard, a frame comprising a base, and a series of ribs journaled to the frame and deflected from a straight line passing through the journals and adapted to be turned to cause the ribs to lie close against the surface or the deflected parts to stand off from the surface of the base, substantially as set forth.

2. In a washboard, a frame comprising a base, and a series of ribs journaled at their ends and intermediate of their ends to the frame and having the parts between the journals deflected, said ribs being adapted to lie against the surface of the base or to be turned to throw the deflected parts away from the said surface, substantially as set forth.

3. In a washboard comprising side strips and a base or back board, ribs journaled at their ends in the side strips and having journals intermediate of their ends, the parts between the respective journals being de-

flected, and fastenings securing the intermediate journals to the said base, the ribs being adapted to lie close against the surface of the base or to be turned to throw the deflected parts outward therefrom, substantially as set forth.

706,198. BALE-TIE. SPENCER MCCAY, Topeka, Kans. Filed Jan. 13, 1902. Serial No. 89,572. (No model.)

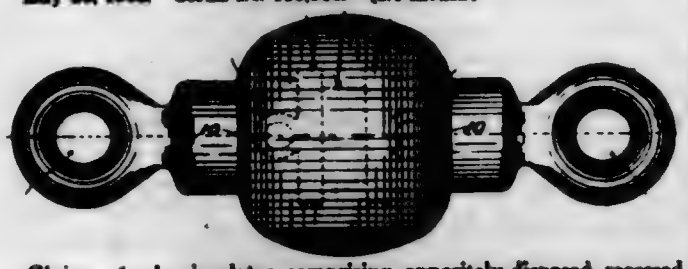
Claim.—1. In a bale-tie, a coupling end comprising entrance and receiving loops separated by a contracted portion having the members facing the entrance-loop diverged and the members facing the receiving-loop abruptly bent to form stop-shoulders, and a coöperating coupling end having a cross-head to pass through the entrance-loop preliminary to passing into the receiving-loop, the side portions of the contracted part being separated by a portion of the end provided with the head riding upon the said diverged members, and said side portions springing together to prevent return of the head into the entrance-loop after passing into the receiving-loop, substantially as set forth.

2. In a bale-tie, a coupling end comprising entrance and receiving loops separated by a contracted portion having diverged members facing the entrance-loop and abrupt shoulders facing the receiving-loop, and a coupling end having a head to pass into the entrance-loop, thence by the contracted portion into the receiving-loop and having its outer bar forwardly deflected to obtain a bearing against a side of the receiving-loop near its inner end to brace and stiffen the joint, substantially as set forth.

3. In a bale-tie, a coupling end comprising entrance and receiving loops separated by a contracted portion having abrupt shoulders facing the receiving-loop and diverged members facing the entrance-loop, and a coupling end having a head inclined to the plane of the aforesaid loops and having its outer bar deflected to obtain a bearing against a loop a distance from the outer end of the receiving-loop, substantially as set forth.

4. In a bale-tie, a coupling end comprising entrance and receiving loops and an intermediate contracted portion, the receiving-loop being approximately of D form and the contracted portion having its side members diverged toward the entrance-loop and abruptly bent toward the receiving-loop to form the straight side thereof, and a second coupling end having a head offset and inclined, the outer bar of said head being outwardly deflected and the inner bar having portions adjacent to the offset portion curved to form side hooks, the outer bar of the head constituting a brace, the parts being constructed for operation substantially in the manner specified.

706,194. INSULATOR. LOUIS MCCARTHY, Boston, Mass. Filed May 26, 1902. Serial No. 108,909. (No model.)



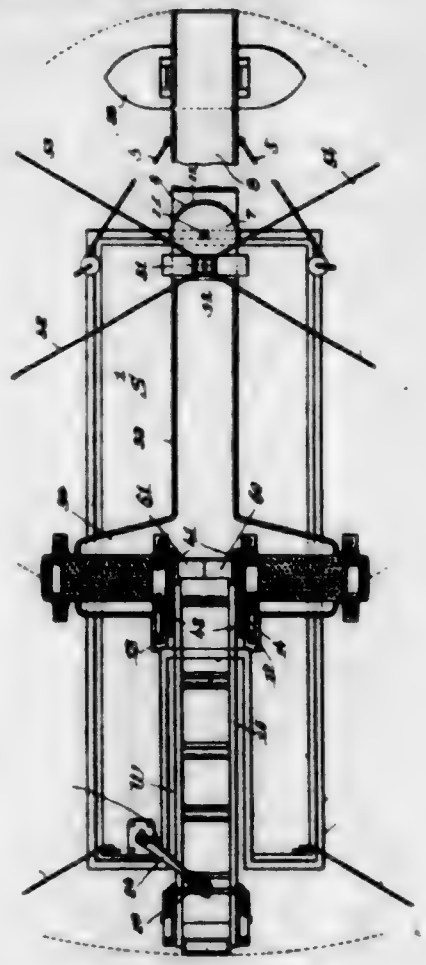
Claim.—1. An insulator comprising oppositely-disposed recessed metallic portions, an intermediate portion of insulating material, means for securing the said insulating material to the oppositely-disposed metallic portions, and a mass of molded insulating material filling the space between the proximate ends of the metallic portions, substantially as described.

2. An insulator comprising metallic end portions, each having a recess therein, the edge of said end piece at the open end of said recess being undercut or beveled, an intermediate connecting-piece of insulating material, secured to each of said end portions within the recess therein, and a mass of insulating material molded over the proximate ends of the end pieces and filling the space between the beveled edges thereof, substantially as described.

3. An insulator comprising recessed cup-shaped end pieces, an intermediate connecting-piece of insulating material, securing-pins passing through said end pieces and said piece of insulating material, and a mass of molded insulating composition in which the said pins and the joint between the end pieces and the insulating connecting-piece are embedded, substantially as described.

4. An insulator comprising end pieces each provided with means for attachment to a flexible support, said end pieces being each provided with a socket or recess, a connecting-piece of insulating material intermediate said end pieces and projecting into the recess in each, means for securing the said end pieces to the said intermediate connecting-piece and a mass of insulating material covering the proximate ends of said end pieces and the space intermediate the same, substantially as described.

706,195. DREDGE. GORDON MCKAY, Newport, R. I. Filed May 2, 1901. Serial No. 58,508. (No model.)



Claim.—1. In an apparatus of the class described, a scow, a dredging device at one end thereof, two oppositely-disposed grizzlies located to receive the material from the dredging device and to discharge the tailings over either side of the scow.

2. In an apparatus of the class described, a scow, a dredging device at one end thereof, two oppositely-disposed grizzlies located to receive the material from the dredging device and deliver the coarser tailings at either side of the scow, combined with a sluice located to receive the fine material from the grizzlies and deliver the fine tailings to the rear of the scow.

3. In an apparatus of the class described, a scow, a dredging device at one end thereof, mechanism for separating the coarse gravel from the fine and valuable material, said separating mechanism having side discharges whereby the coarse gravel is deposited either side of the scow, a sluice adapted to receive the fine material from the separating mechanisms, said sluice extending back from the scow and having its projecting end pivotally mounted, and means to maintain the pivoted end of the sluice in any adjusted position.

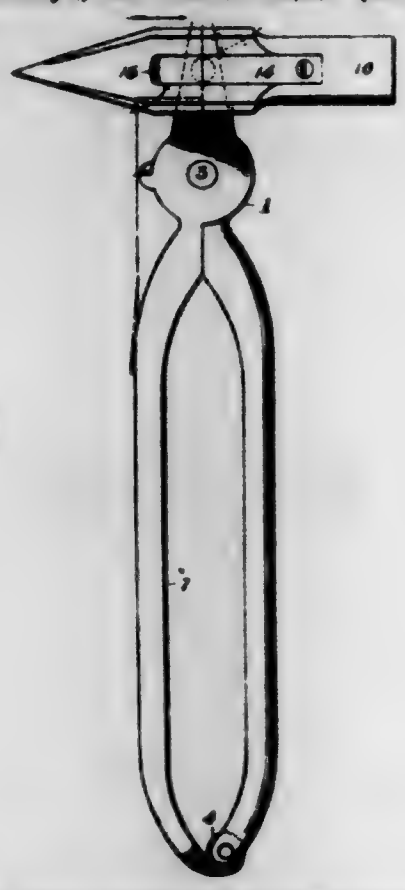
4. In an apparatus of the class described, a scow pivoted for swinging movement about one end, an excavating device on the front end of said scow, two oppositely-disposed rotating grizzlies or screens in front of the pivotal point of the scow, and projecting at their discharge ends over the sides of the scow, said grizzlies receiving material from the excavator and operating to discharge the coarse tailings on both sides of the scow, a sluice adapted to receive fine material from the grizzlies, said sluice being attached to the scow and extending back thereof a distance approximately equal to the length of the scow, and a float to support the end of the sluice, whereby tailings from the sluice are deposited on top of the tailings from the grizzlies

5. In an apparatus of the class described, a scow pivoted for swinging movement about one end, an excavating device on the front end of said scow, two oppositely-disposed rotating grizzlies or screens in front of the pivotal point of the scow, said grizzlies receiving material from the excavating device and operating to discharge the coarse tailings on either side of the scow, a sluice adapted to receive the fine material from the grizzlies, said sluice being attached to the scow and extending back thereof a distance approximately equal to the length of the scow.

6. In an apparatus of the class described, a scow or float, a dredge carried thereby, means to separate the coarse gravel from the fine and valuable material, a sluice to receive the fine material, said sluice extending

hook from the screw, and comprising two sections, one of said sections rigid with the screw and having at its end a joint articulating with the end of the other section, and means for varying the relative positions of the two sections and for holding them in any adjusted relative position, whereby one section may have a lateral swinging movement relative to the other or may be made rigid therewith.

706,196. COMPOUND TOOL. WINFIELD OFFUTT, Washington, D. C. Filed May 2, 1902. Serial No. 105,642. (No model.)



Claim.—1. The combination with the pivoted jaws of a pliers and arms extending therefrom; of a cutting-disk journaled in the end of one arm, and a claw at the end of the other arm adapted to extend over, and guard, the cutter.

2. The combination with a pliers having a jaw grooved in its inner face; of a head adapted to receive the closed jaws of the pliers, and means in the head for engaging the groove.

3. The combination with the jaws of a pliers; of a head having a recess for the reception of the closed jaws, and means for automatically locking the jaws in the recess.

4. The combination with the jaws of a pliers; of a head having a recess therein for the reception of the closed jaws, and a spring-pressed lug adapted to project into the recess and engage the jaws.

5. The combination with the jaws of a pliers; of a head having a recess for the reception of the closed jaws, a stud normally extending into the recess and adapted to engage the jaws, and a spring-strip secured to the head and stud and adapted to hold the stud in engagement.

6. The combination with the jaws of a pliers; of a head having a recess therein for the reception of the closed jaws, a spring-strip secured at one end within a groove in the head, a stud extending from said strip into the recess and adapted to lock the jaws therein, and an outwardly-turned end to the strip.

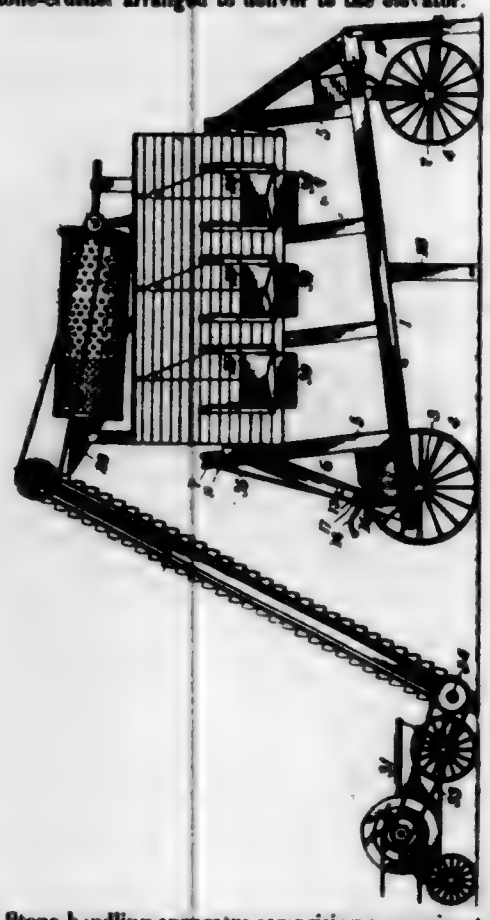
7. The combination with a pliers having jaws provided with grooves in their inner faces; of a head having a recess therein for the reception of the closed jaws, a spring-strip secured to the side of the head, and a beveled stud extending from the strip and into the recess and adapted to engage the grooves and lock the jaws in the recess.

706,197. STONE-HANDLING APPARATUS. CHARLES H. OWEN, Mechanicsburg, Pa. Filed Apr. 24, 1902. Serial No. 104,483. (No model.)

Claim.—1. Stone-handling apparatus comprising a carrying-truck, a portable bin mounted thereon, means for raising and lowering the bin, and a stone-elevator adapted to deliver to the bin, substantially as described.

2. Stone-handling apparatus comprising a carrying-truck, a portable bin mounted thereon, means for raising and lowering the bin, a screen at the top of the bin for receiving stone, and a stone-elevator adapted to discharge into the screen, substantially as described.

3. Stone-handling apparatus comprising a carrying-truck, a portable bin mounted thereon, means for raising and lowering the bin, a screen at the top of the bin, a stone-elevator arranged to discharge into the screen, and a stone-crusher arranged to deliver to the elevator.



4. Stone-handling apparatus comprising a carrying-truck, a portable stone-bin thereon, means for raising and lowering the bin, a screen mounted at the top of the bin and adjustable therewith to receive the stone from an elevator and direct the same into the bin, a stone-elevator arranged to discharge into the screen, and a stone-crusher to which the elevator is connected and upon which it is adjustable.

5. Stone-handling apparatus comprising a carrying-truck, a portable stone-bin mounted thereon, means for raising and lowering the bin and the screen, a rotary stone-grading screen at the top of the bin arranged to receive the stone and discharge into the bin, and a stone-elevator arranged to deliver to the screen.

6. Stone-handling apparatus, comprising a carrying-truck, a stone-bin mounted thereon, a stone-grading screen at the top of the bin, and means for independently raising and lowering the opposite ends of the bin.

7. Stone-handling apparatus comprising a carrying-truck, a bin mounted thereon, a stone-grading screen at the top of the bin, means for independently raising and lowering the opposite ends of the bin, and movable props for supporting the bin when elevated.

8. Stone-handling apparatus comprising a portable truck, a stone-bin mounted thereon, a stone-grading screen at the top of the bin, means for raising and lowering the bin, and movable props for bracing and supporting the truck and bin, substantially as described.

9. Stone-handling apparatus comprising a portable truck, a stone-bin mounted thereon, a stone-grading screen at the top of the bin, means for raising and lowering the bin on the truck, and truck-supporting props or braces having a hinged connection with the truck-frame, substantially as described.

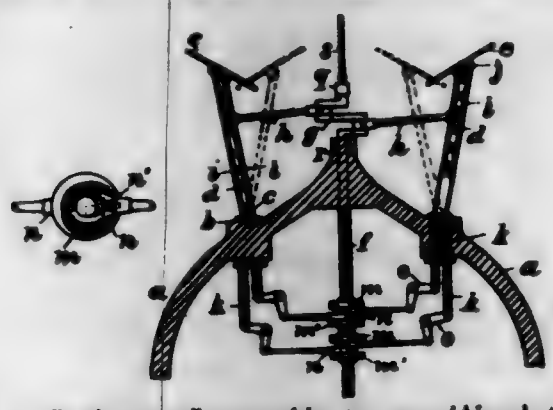
10. Stone-handling apparatus comprising a portable truck, having a longitudinally-inclined frame, a stone-bin mounted thereon, a stone-grading screen at the top of the bin, means for raising and lowering the bin, and removable props or braces adapted to be placed with a wedging fit between the inclined truck-frame and the elevated bin, substantially as described.

706,198. VIBRATING PROPELLER. WILLIAM W. PEARCE, New York, N. Y. Filed Dec. 10, 1901. Serial No. 85,358. (No model.)

Claim.—1. A vibrating propeller comprising two arms *d* hinged at opposite sides of the driving-shaft *f*, the cranks *g* upon the driving-shaft, the rods *h* connecting the cranks with the arms to vibrate the same, the blades *e* pivoted upon the ends of the arms, and means for tipping the blades when moved in opposite directions.

2. A vibrating propeller comprising two arms *d* hinged at opposite sides of the driving-shaft *f*, the cranks *g* upon the driving-shaft, in the rear of the stern-bearing *r*, the rods *h* connecting the cranks with the arms to vibrate the same, the blades *e* pivoted upon the ends of the arms,

the plungers *k* extended through the hull of the vessel and provided with means for reciprocating the same, and the links *i* actuated by the plungers to tip the blades in opposite directions, substantially as herein set forth.



3. A vibrating propeller comprising two arms *d* hinged at opposite sides of the driving-shaft *f*, the cranks *g* upon the driving-shaft in the rear of the stern-bearing *r*, the rods *h* connecting the cranks with the arms to vibrate the same, the blades *a* pivoted upon the ends of the arms, the plungers *k* extended through the hull of the vessel, the links *i* connecting the plungers with the blades at opposite sides of the arm, cams upon the driving-shaft *f*, and connections from the cams to the plungers to suitably reciprocate the same and tip the blades, substantially as herein set forth.

4. A vibrating propeller comprising two arms *d* hinged at opposite sides of the driving-shaft *f*, the cranks *g* upon the driving-shaft, the rods *h* connecting the cranks with the arms to vibrate the same, links *i* pivoted to the blades at opposite sides of the arms, with means for reciprocating the links to tip the blades as set forth, and the stops *p* attached to the arms to support the blades when wholly tipped, substantially as herein set forth.

5. A vibrating propeller comprising two arms *d* hinged at opposite sides of the driving-shaft *f*, the cranks *g* upon the driving-shaft, the rods *h* connecting the cranks with the arms to vibrate the same, links *i* pivoted to the blades at opposite sides of the arms with means for reciprocating the links to tip the blades as set forth, and the arms being provided with the forked extensions *d'* each having the stops *p* projecting from opposite sides thereof to support the blades when wholly tipped, substantially as herein set forth.

6. A vibrating propeller comprising two arms *d* hinged at opposite sides of the driving-shaft *f*, the cranks *g* upon the driving-shaft, the rods *h* connecting the cranks with the arms to vibrate the same, links *i* pivoted to the blades at opposite sides of the arms, the arms *d* being forked at the base and having the feet pivoted upon separate lugs *c*, and means extended through the hull of the vessel between each feet for reciprocating the links and tipping the blades, substantially as herein set forth.

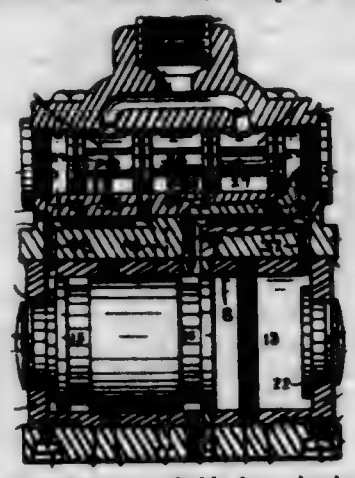
706,199. LOCK AND EXTRACTOR MECHANISM FOR FIRE-ARMS. NICOLAS PIEPER, Liege, Belgium. Filed July 1, 1901. Serial No. 66,810. (No model.)

Claim.—1. In a bolt-gun, the combination with the gun-body having a slot in its lower wall, the bolt, and the means for operating the bolt, of the extractor movable in said slot and adapted to be actuated by said bolt, the trigger-spring consisting of a flat blade arranged parallel to and lying against the body of the gun and forming a bearing in which the extractor slides, and the trigger pivoted to the rear end of the spring, substantially as described.

2. In a bolt-gun, the combination with the gun-body having a slot in its lower wall, the bolt, the striker, and the cocking means, of the trigger-spring consisting of a flat blade secured at its forward end to the gun-body and occupying a position parallel thereto and having a rear at its opposite end, the trigger pivoted to said spring, and the extractor movable in said slot and supported thereon by the trigger-spring, substantially as described.

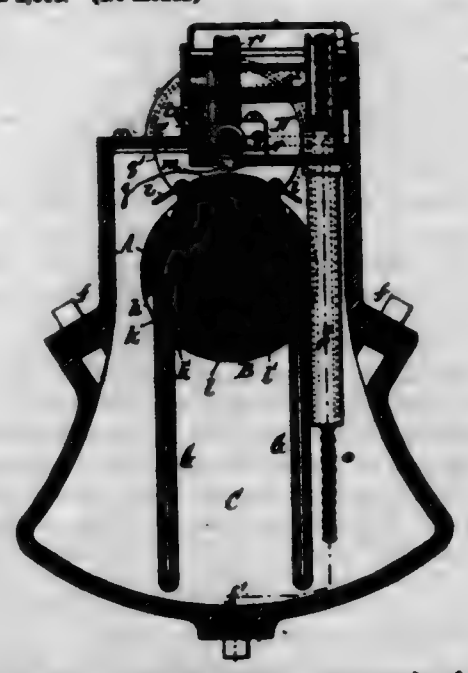
706,200. BOILER-TUBE CLEANER. OSCAR C. CRAMBAUER, St. Louis, Mo., assignor of one-half to Nathan Holbert, St. Louis, Mo. Filed Mar. 24, 1902. Serial No. 99,764. (No model.)

Claim.—1. A boiler-tube cleaner comprising a piston-casing adapted to slide back and forth in the boiler-tubes and having a transverse bore forming a hammer-piston chamber; the ends of said chamber being enlarged to form die-holder seats; a hammer-piston slidingly mounted in said chamber; said piston having valve-releasing-port-connecting grooves in its periphery; die-holders slidingly mounted in said die-holder seats, dies carried by said die-holders, a valve-casing attached to the piston-casing and having a transverse bore parallel with the piston-chamber and forming a valve-chamber; a valve slidingly mounted in said valve-chamber and having pressure-port-connecting grooves in its periphery, and having an exhaust-port-connecting groove in its periphery and having valve-shifting ports connecting the pressure to each end of the valve, plugs closing the ends of said valve-chamber and a steam-supply pipe connected to said valve-casing; there being pressure-ports leading from the supply-pipe to the valve-chamber; and there being pressure-ports leading from the valve-chamber to the piston-chamber so that the reciprocation of the valve admits pressure first to one end of the valve and then to the other; and there being an exhaust-port so that the reciprocation of the valve will release the exhaust from one end of the valve, while the pressure is being admitted to the other end, and there being valve-releasing ports leading from said valve-chamber to the piston-chamber and there being second valve-releasing ports leading from the piston-chamber so that the reciprocation of the piston will connect said first and second valve-releasing ports to release the pressure first from one end of the valve and then from the other end, as required to reciprocate the valve.



2. In a boiler-tube cleaner, a suitable frame having a transverse bore forming a hammer-piston chamber, die-holders mounted in the ends of said chamber, a hammer-piston mounted in said chamber, dies carried by said die-holders, steam-ports leading to said piston-chamber, and an automatic valve for admitting the steam first to one end of the piston and then the other, as required to reciprocate the hammer-piston, and cause it to strike the dies, said dies being held outwardly against the inner surface of the boiler-tube by the steam-pressure.

706,201. LUBRICATOR. WILLARD F. RICHARDS, Buffalo, N. Y., assignor to Charles M. Gould, New York, N. Y. Filed Jan. 19, 1900. Serial No. 2,013. (No model.)



Claim.—1. The combination with an oil-reservoir, of a horizontal bearing-sleeve arranged in the upper portion of said reservoir and provided in its side wall with an aperture which intersects the bore of the

sleeve, and a stationary wick supported on said sleeve and immersed in the oil in said reservoir and having its upper portion arranged in said aperture so as to lie against the shaft journaled in said bearing-sleeve, substantially as set forth.

2. The combination with a journal, and an oil-reservoir, of a horizontal bearing-sleeve arranged in the upper portion of said reservoir and provided with an upper side over the journal and provided in its side walls with openings which open into the bore of the sleeve, and a wick supported upon the upper side of said sleeve and having depending branches which pass downwardly through said openings and are immersed in the oil in said reservoir, substantially as set forth.

3. The combination with an oil-reservoir, of a bearing-sleeve provided on opposite sides thereof with openings which intersect its bore, and a wick having depending branches which pass through said openings and are immersed in the oil of said reservoir, and which are provided at their exposed, upper ends with rings or handles for withdrawing the wick from the openings of the sleeve, substantially as set forth.

4. The combination with an oil-reservoir, of a bearing-sleeve provided in its side wall with a wick-opening which intersects its bore, and a transverse channel which leads from the inner lower edge of said opening to the bottom of the sleeve-bore, and a wick supported by said sleeve and arranged in said opening and immersed in the oil in said reservoir, substantially as set forth.

5. The combination with an oil-reservoir, of a bearing-sleeve provided in its side with an opening which intersects its bore, a shelf or ledge arranged at the lower, inner wall of said opening, a longitudinal channel arranged in the bottom of the sleeve-bore, and a transverse channel or channels leading from said ledge to said longitudinal channel, and a wick arranged in said opening and immersed in the oil in said reservoir, substantially as set forth.

6. A bearing-sleeve provided in its side with a wick-opening which intersects its bore, and having a recess in its lower, inner wall which forms a ledge or shelf adapted to receive any surplus oil flowing down the wick, a longitudinal channel arranged in the bottom of the sleeve-bore, and a transverse channel or channels leading from said ledge to said longitudinal channel, substantially as set forth.

7. The combination with a shaft to be lubricated, of a main oil-reservoir arranged below said shaft, an auxiliary reservoir arranged above said shaft and provided with a discharge-opening, a pulley arranged in said auxiliary reservoir, a depending flexible feed member running loosely over said pulley and dipping into the oil in said main reservoir, and means for turning said pulley, substantially as set forth.

8. The combination with a shaft to be lubricated, of a main oil-reservoir arranged below said shaft, an auxiliary reservoir arranged above said shaft and provided with a discharge-opening, a pulley arranged in said auxiliary reservoir, a depending flexible feed member running loosely over said pulley and dipping into the oil in said main reservoir, and intermediate gearing whereby said pulley is rotated from said shaft, substantially as set forth.

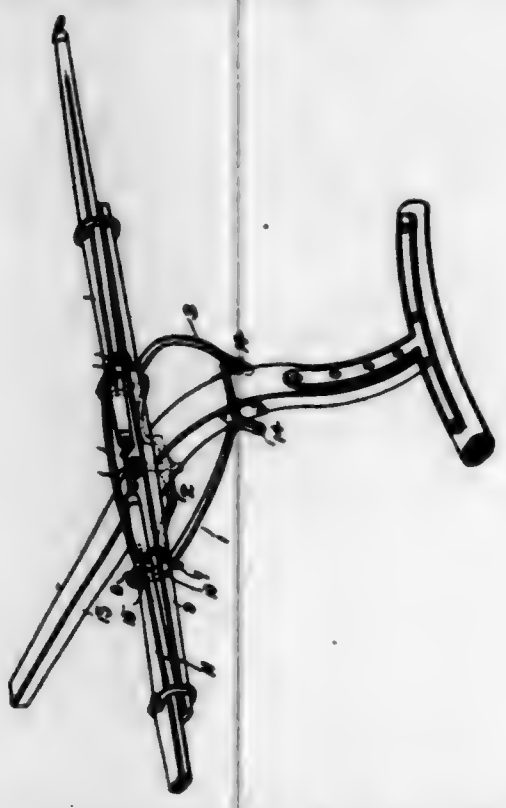
9. The combination with a shaft to be lubricated, of a main oil-reservoir arranged below said shaft, an auxiliary reservoir arranged above said shaft and provided with a discharge-opening, a pulley arranged in said auxiliary reservoir, a depending flexible feed member running loosely over said pulley and dipping into the oil in said main reservoir, a worm-wheel mounted on the shaft of said pulley, and an actuating-shaft having a friction-wheel which runs in contact with the lubricated shaft and a worm which meshes with said worm-wheel, substantially as set forth.

10. The combination with a shaft to be lubricated and a main reservoir arranged below the same, of a bottomless casing arranged above said shaft, a vertically-movable auxiliary oil reservoir capable of sliding freely in said casing and provided in its bottom with a discharge-opening, a pulley mounted on a horizontal shaft journaled in said auxiliary reservoir, an endless flexible feed member depending from said pulley and dipping into said main reservoir, and an actuating-shaft journaled in said auxiliary reservoir and having a friction-wheel which runs in contact with the shaft to be lubricated, and a worm which meshes with a worm-wheel mounted on the shaft of said pulley, substantially as set forth.

11. The combination with a shaft to be lubricated, of a main oil-reservoir arranged underneath the shaft, an auxiliary oil-reservoir arranged above the shaft and provided in its bottom with a discharge-opening, a wick depending from the shaft into said lower reservoir and exposed at the upper side of the shaft, a pulley journaled in the auxiliary reservoir, an endless flexible feed member suspended from said pulley and dipping into the oil in the lower reservoir, and intermediate gearing whereby said pulley is turned from the lubricated shaft, substantially as set forth.

12. The combination with a shaft, of a main oil-reservoir arranged below the shaft, an auxiliary reservoir arranged above the main reservoir and provided with a discharge-opening, a pulley arranged in said auxiliary reservoir, a flexible feed member running over said pulley and dipping into the oil in said main reservoir, means for driving said pulley, and a wick located between said discharge-opening and the shaft for catching any grit or sediment in the oil, substantially as set forth.

706,202. DRAFT-EQUALIZER. WILLIAM B. RIVERS, Tracy, Iowa. Filed Jan. 11, 1902. Serial No. 89,355. (No model.)



Claim.—1. A combined draft-equalizer and support provided at opposite sides with loops designed to be secured to a doubletree and receiving the inner portions of the singletree and permitting a limited movement of the same, said draft-equalizer and support being also provided with means for engaging the tongue to limit the movement of the doubletree, substantially as described.

2. A combined draft-equalizer and support comprising opposite loops designed to be secured to a doubletree and arranged to receive the inner portions of the singletree to permit a limited movement thereof, and a rearwardly-extending bar provided at opposite sides of the tongue or pole with means for engaging the same to limit the swing of the doubletree, substantially as described.

3. A combined draft-equalizer and support comprising opposite loops designed to be secured to a doubletree and arranged to receive the inner portions of the singletrees, and the approximately U-shaped rearwardly-extending bar resting upon the pole or tongue and provided at opposite sides of the same with depending lugs, substantially as described.

4. A combined draft-equalizer and support comprising the opposite loops having reduced lower portions to receive the doubletree and provided with enlarged upper portions to permit a limited swing of the singletrees, and means for connecting the loops, substantially as described.

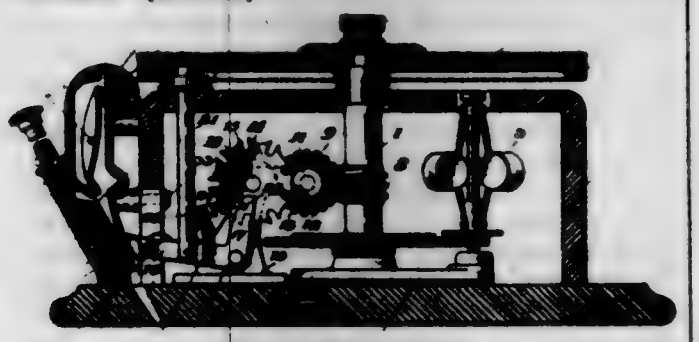
5. A combined draft-equalizer and support comprising the opposite loops designed to be secured to the doubletree and arranged to receive the inner portions of the singletrees to limit the swing thereof, and means for connecting the loops with each other and with the tongue or pole, substantially as described.

6. A combined draft-equalizer and support comprising the opposite loops designed to be secured to the doubletree and arranged to receive the inner portions of the singletrees, and the top bar connecting the loops and extending over the inner ends of the singletrees to form a guard, substantially as described.

7. A combined draft-equalizer and support comprising the opposite loops designed to be secured to a doubletree and arranged to receive the inner portions of the singletrees, and the bottom bar connecting the loops and pivoted to the pole and extending beneath the latter, substantially as described.

8. A combined draft-equalizer and support comprising the opposite loops designed to be secured to a doubletree and arranged to receive the inner portions of the singletrees, the bottom bar connecting the loops and extending beneath and pivotally connected to the tongue or pole, the top bar connecting the loops and extending over the inner portions of the singletrees and forming a guard, and the rearwardly-extending bar supported by the tongue or pole and provided with means for engaging the same, substantially as described.

706,208. COIN-OPERATED TALKING-MACHINE. DELFORD G. ROYAL, London, England, assignor to the Gramophone and Typewriter, Limited, London, England, a Corporation. Filed Feb. 7, 1901. Serial No. 46,300. (No model.)



Claim.—1. The combination with a spring-motor, a turn-table driven thereby, a bell-crank lever pivotally mounted on a supporting-frame, a locking-bolt pivoted to the lower arm of the bell-crank adapted to engage and lock the turn-table, coin-controlled mechanism adapted to tilt the bell-crank and withdraw the locking-bolt, means for locking the bell-crank in its tilted position, and mechanism driven by the motor for automatically tripping the bell-crank to return it to normal position, for the purpose substantially as described.

2. The combination with a talking-machine, a spring-motor for running the record-support of same, a bell-crank lever pivoted to a supporting-frame, a vertically-disposed locking-bolt pivoted at one end to one arm of said bell-crank adapted to engage the record-support and normally lock the same, a coin-holding device adapted to receive and hold the coin, a push-bar or plunger in said coin-holder, mechanism carried by the push-bar adapted when said push-bar is operated to engage the coin and be thrown into engagement with the bell-crank to release the motor, and mechanism for resetting the bell-crank and automatically stopping the motor substantially as described.

3. The combination with the spring-motor and turn-table, of means for locking said turn-table against rotation, a coin-holding device secured to the motor-casing, means for holding a deposited coin in said holder, a push-bar carried by the coin-holder, and mechanism carried by the push-bar adapted to be actuated by the coin to engage the locking mechanism of the motor and simultaneously release the same and eject the coin, substantially as described.

4. The combination with the spring-motor and turn-table, of means for locking said turn-table against rotation, a coin-holding device secured to the motor-casing, means for holding a deposited coin in said holder, a push-bar carried by the coin-holder, a pivoted detent carried by the push-bar adapted to engage the edge of the coin when said push-bar is depressed and be thrown in engagement with the motor-locking mechanism to release the same and start the machine, substantially as described.

5. The combination with the spring-motor and turn-table, of means for locking said turn-table against rotation, a coin-holding device secured to the motor-casing, means for holding a deposited coin in said holder, a push-bar adapted to engage the edge of the coin when depressed and thereby be thrown into engagement with the motor-locking mechanism to release the same, and simultaneously eject the coin, and means for returning the push-bar to normal position, substantially as described.

6. The combination with a spring-motor, a driving-spindle driven thereby, a turn table secured to said driving-spindle so as to revolve therewith, a bell-crank lever pivoted to a suitable support, a locking-bolt pivoted to the lower arm of said bell-crank adapted to engage and lock the turn-table, means for holding the bell-crank in its locked position, a star-wheel located adjacent to the upper arm of the bell-crank, a pin carried by said star-wheel adapted to engage the bell-crank and trip the same on each revolution of the star-wheel, and gearing connecting the said star-wheel with the driving-spindle of the motor, substantially as described.

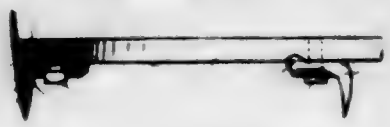
7. The combination with a spring-motor, a driving-spindle, a turn-table secured thereto, a bell-crank lever pivoted on a supporting-frame, a locking-bolt pivoted to the lower arm of the bell-crank adapted to normally engage the turn-table, a projecting pin carried by the upper arm of the bell-crank, a spring-pressed pawl pivoted to the machine-frame having its hooked end adapted to engage the pin and hold the lower arm of the bell-crank down, a spring secured to the frame of the machine and to the lower arm of the bell-crank, and a tripping mechanism operatively connected to the motor-spindle for releasing the pawl and allowing the bell-crank to tilt, for the purpose substantially as described.

706,204. WATCH-WINDING DEVICE. GEORGE H. SAWYER, Fishkill Landing, N. Y. Filed July 31, 1901. Serial No. 70,226. (No model.)

Claim.—1. In a winding attachment for watches, the combination with a winding-stem and its head, of a cap hinged to the head, a pin carried by the cap having a notched edge and a protuberance on the head engaging the pin, substantially as described.

2. In a stem-winding attachment for watches, a winding-stem and its head, ears formed with the head, a cap having a lug hinged to the ears, a pin projecting from the edge of the head, a pin carried by the cap and standing at right angles to the surface thereof, said pin having a recess to receive the pin of the head as for the purpose described.

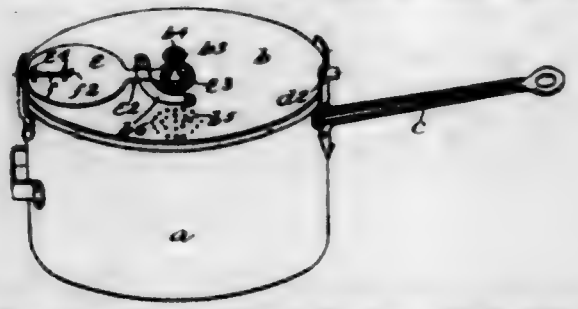
706,205. CALK EQUIPPED HORSESHOE. ARTHUR F. SCHOFIELD, Westford, Conn. Filed Apr. 21, 1902. Serial No. 103,857. (No model.)



Claim.—1. The attachable and detachable calk for the front of the horseshoe made of one piece of sheet material doubled upon itself, sharpened at the double, and turned off laterally into a bearing-wing at the rear.

2. The attachable and detachable calk for the front of the horseshoe made of one piece of sheet metal composed of layers of material of different degrees of hardness, said sheet being doubled upon itself and sharpened at the double till the harder layer of material forms the edge, and turned off laterally into a bearing-wing.

706,206. COOKING APPARATUS. SIGMUND SILBERMANN, New York, N. Y. Filed Mar. 18, 1902. Serial No. 98,855. (No model.)



Claim.—A cooking utensil comprising a vessel having a cover provided at one side with perforations or openings and with a pivoted shield adapted to cover said openings, said vessel being also provided at its opposite sides with upwardly-directed members, and said cover being provided at one side with a lug or projection adapted to pass through one of said members, and said shield being provided with a radially-movable pin adapted to pass through the other of said members, substantially as shown and described.

706,207. BANANA-CRATE. WILLIAM H. SIMPSON, Chicago, Ill. Filed Dec. 31, 1901. Serial No. 87,948. (No model.)

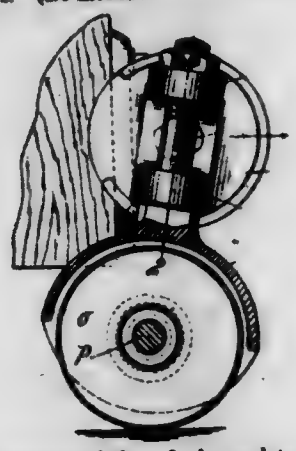
Claim.—A banana-crate comprising two two-part polygonal heads, one of which is provided with a central orifice, sides connecting the ends, reinforcing-bands exteriorly embracing the sides intermediate of their ends and having their terminals formed into interengaging hinge members, a packing secured to the interior of each of the sides, a yielding cushion interposed between the packing and the sides, and means for holding the sides assembled.

706,208. WRENCH. ANDREW I. SLATER, Butte, Mont. Filed May 9, 1902. Serial No. 106,993. (No model.)

Claim.—In a wrench, the combination with a handle-bar having ratchet-teeth and provided with a fixed jaw, of a sliding frame mounted to slide upon said handle, a jaw having a shank pivoted in said sliding

frame, a spring exerting pressure upon said jaw to throw its face at an angle to the face of the fixed jaw, a lever pivoted to the sliding frame and provided with a straight spring which engages the rear side of the jaw, said spring serving the double function of paralleling the operative face of the movable jaw with the operative face of the fixed jaw when said lever is depressed, and when said lever is released, said spring acting to lock said lever in engagement with the ratchet-teeth and hold the sliding frame in locked adjustment thereto, substantially as set forth.

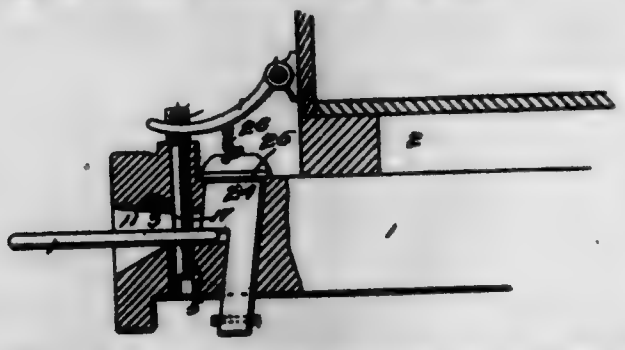
706,209. CASTER. WILLIAM J. SUMNER, Holyoke, Mass., assignor of one-half to ANNE A. COBURN, Holyoke, Mass. Filed May 20, 1902. Serial No. 108,151. (No model.)



Claim.—1. A caster consisting of a base-plate adapted to be secured in a vertical plane to an article to be supported thereby; a swivel-plate pivotally supported on said base-plate, means for rotatably supporting a post vertically on said swivel-plate, a wheel suitably supported on the lower end of said post; and means whereby the swivel-plate may have a limited oscillatory movement on the base-plate, whereby said post may be swung to a position oblique to the perpendicular, in the plane of rotation of the wheel only.

2. A caster consisting of a plate adapted to be secured to an article to be supported thereby; a base-plate integral with said first-named plate located at right angles thereto and lying in a vertical plane; a swivel-plate pivotally supported on the base-plate; a post rotatably supported on the swivel-plate in a perpendicular position, a broken flange on the base-plate, and a projection on the swivel-plate lying between the ends of said flange, whereby the oscillations of the swivel-plate may be limited.

706,210. CAR-COUPLING. JAMES L. SUTHERLAND, Mayfield, Ky. Filed Apr. 28, 1902. Serial No. 105,102. (No model.)



Claim.—1. In a car-coupling, the combination with a draw-head, and a coupling-pin, of an uncoupling mechanism having an arm connected with and adapted to lift the coupling-pin, means for supporting and tripping the coupling-pin, and a link-engaging bar mounted in the draw-head in rear of the coupling-pin and connected with the said arm and capable of upward and downward movement independently of the pin, substantially as and for the purpose described.

2. In a car-coupling, the combination with a draw-head, and a coupling-pin, of an uncoupling mechanism having an arm connected with and adapted to lift the coupling-pin, means for supporting and tripping the coupling-pin, a link-engaging bar mounted in the draw-head in rear of the coupling-pin and capable of movement independently of the coupling-pin, and a flexible connection extending from the arm to the link-engaging bar, substantially as described.

3. In a car-coupling, the combination with a draw-head, of a coupling-pin having a bifurcated upper portion, an antifriction-roller mounted in the bifurcation, an uncoupling mechanism having a curved arm arranged within the bifurcation and receiving the roller, a link-engaging bar provided with a flexible connection secured to the arm, and means for supporting and tripping the coupling-pin, substantially as described.

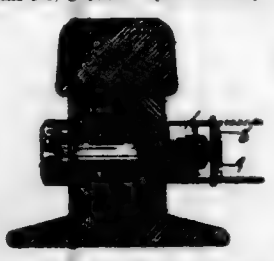
4. In a car-coupling, the combination with a draw-head provided at one side with a horizontal groove and having openings at the front and rear of the same, a push-bar having a stem and provided with a recess and mounted in the groove and openings of the draw-head, a spring disposed on the stem of the push-bar and engaging the same, and a lever fulcrumed between its ends on the draw-head and having its inner arm arranged to support the coupling-pin in an elevated position, its outer arm being detachably arranged in the recess of the push-bar and extended beyond the draw-head, substantially as described.

706,211. TROLLEY-WHEEL. RUDOLPH H. APELT, Boston, Mass. Filed Mar. 30, 1901. Renewed Dec. 19, 1901. Serial No. 86,534. (No model.)

Claim.—1. In a trolley-wheel, the combination, with a flange-plate provided with a hub having an oil-hole in it, of a second flange-plate slidable on the said hub, one of the said flange-plates being also provided with a series of lateral projections, and a tread-ring provided with grooves which slide over the said projections, an oil-chamber being formed by the two said flange-plates around the said hub and within the tread-ring, substantially as set forth.

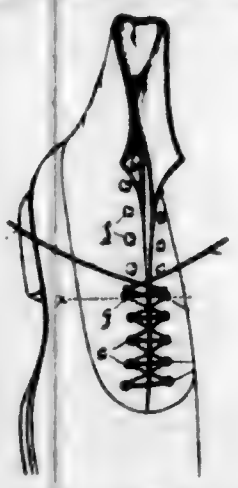
2. In a trolley-wheel, the combination, with a flange-plate provided with a hub, of a flange-plate secured on the said hub and provided with a series of projections, and a tread-ring provided with grooves which engage with the said projections and having also a central opening which forms an oil-chamber between the said flange-plates substantially as set forth.

706,212. NUT-LOCK. OCTAV BAILLARGEON, Cohoes, N. Y. Filed Feb. 20, 1902. Serial No. 94,861. (No model.)



Claim.—The combination with a threaded bolt having a cross-groove in its threaded end and a similarly-threaded nut having a plurality of plane sides; of a sheet-metal yoke having a bolt-receiving aperture and extended arms engageable with the plane sides of the nut; and a keeper having a part adapted to enter the cross-groove of the bolt and provided with means for connecting the yoke-arms therewith whereby the keeper is adapted to hold the yoke-arms interlocked with the plane sides of the nut, and the arms to hold the keeper interlocked with the bolt, substantially as described.

706,213. LACING-EYE FOR SHOES, &c. LOUIS BALLBACH, Detroit, Mich. Filed Dec. 7, 1900. Serial No. 38,991. (No model.)

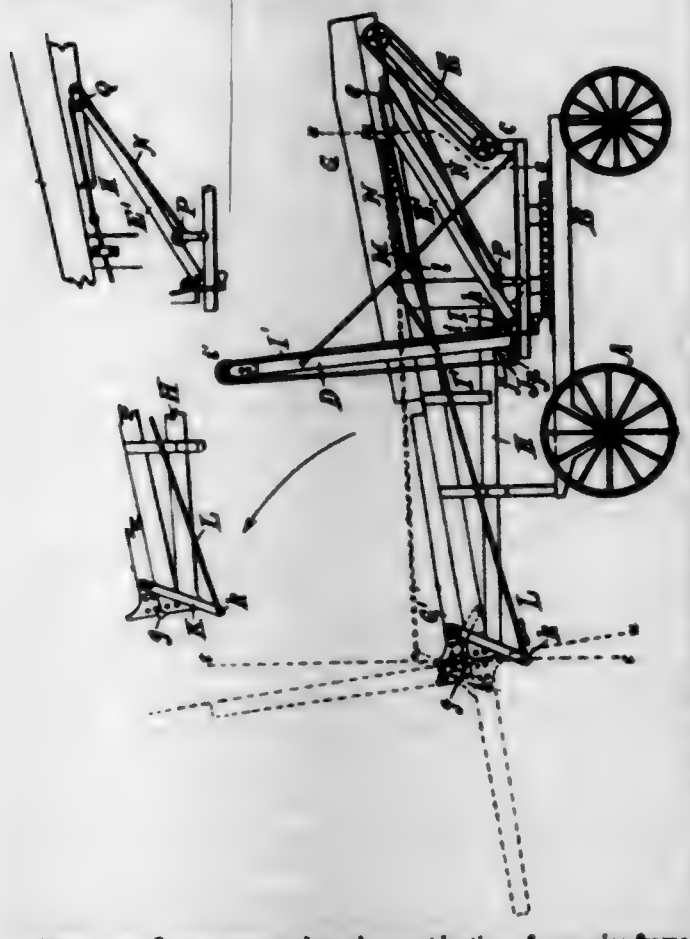


Claim.—1. A lacing-hook consisting of an eyelet having means for fastening it to the garment, and a hook formed with a shank hinge-con-

nected at one end to the eyelet in a plane parallel to and below the plane of the face of the eyelet and adapted to bear against the face of the eyelet at or near its opposite end, said end having an outwardly-turned hook portion forming an open inlet into the hook above the shank portion whereby the lacing-string may be engaged into the hook when the hook is folded down upon the eyelet and produce a clamping action between the shank and the eyelet to prevent another portion of the lacing-string drawn through the eyelet itself from being drawn through the eyelet, by the tension of that portion of the lacing-string engaged with the hook.

2. A lacing-hook consisting of an eyelet having means for securing it to the fabric, and a hook formed with a shank hinge-connected at one end to the eyelet in a plane parallel to and below the plane of the face of the eyelet and provided upon its under side with a bearing portion adapted to project into the eyelet, the free end of the shank having an outwardly-turned hook portion forming an open inlet into the hook above the shank portion, whereby the lacing-string may be engaged into the open mouth of the hook when the hook is folded down upon the eyelet and thereby produce a clamping action upon another portion of the lacing-string drawn through the eyelet itself.

706,214. **STRAW-STACKER.** JOHN B. BARTHOLOMEW, Peoria, Ill., assignor, by mesne assignments, to Avery Manufacturing Company, Peoria, Ill., a Corporation of Illinois. Filed Sept. 5, 1894. Serial No. 522,434. (No model.)



Claim.—1. In a straw-stacker, the combination of a carrier-frame having two sections hinged together, draft devices for moving the outer section around its hinge-axis, and a guide or holder for the said draft devices on the inner section, said draft devices being connected to the outer section at a point substantially as set forth whereby said attaching-point comes to the line through the guide and the hinge-axis at the time the center of gravity of the outer section crosses the vertical plane of the hinge-axis, as described.

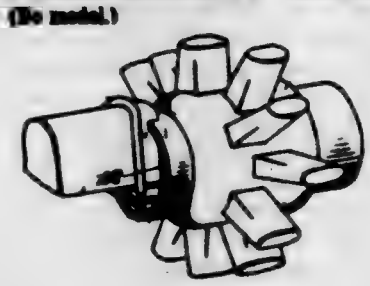
2. In a straw-stacker, the combination with the carrier-frame consisting of two sections hinged together, of an arm or bar on the outer section, inclined toward the inner section when the sections are in line, and inclined away from the inner section when the outer one is folded, and draft devices connected to said arm, said parts being arranged substantially as described whereby a positive pull will be exerted on the draft devices by the gravity of the outer section at all points in its path of movement around its hinge-axis, substantially as set forth.

3. In a straw-stacker, the combination of a base or support, an inner carrier-section hinged to said support, an outer carrier-section hinged to the inner section, draft devices connected to the outer section and arranged substantially as set forth to exert a pulling force in one direction on said outer section during a part of its movement around its hinge, and to exert a pulling force thereon in the opposite direction during the remainder of its movement around said hinge, substantially as described.

4. In a straw-stacker, the combination of a base or support, an inner carrier-section hinged thereto, an outer carrier-section hinged to the inner, means for moving both carrier-sections from a relatively low position where the center of gravity of the outer section is outside of the vertical plane of the hinge of said section when the sections are at right angles to each other to a relatively high position where the center of gravity of the outer section is inside of the said hinge plane when the sections are at right angles to each other, and a draft device connected to the outer section at a point substantially as described, whereby it exerts a positive pull on the outer section and moves it to a position at right angles to the inner section, both when the entire carrier is in its lower position and when it is in its upper position, substantially as set forth.

5. In a stacker, the combination of a lower section horizontally vibratable, an upper section pivoted on the lower section to swing vertically forward and downward and backward to fold into portable position, an extension of the upper section behind the pivot thereof, a guide on the lower section, and a line having means connecting it with the extension and extended around the guide, said guide being located approximately on a right line drawn through the pivot and through the connection of the line with the extension when the vertically-swinging section is in a vertical position.

706,215. **WASHER FOR VEHICLE-AXLES.** CLARENCE BUTNER, and ROBERT L. BUTNER, Littlerock, S. C. Filed Dec. 4, 1901. Serial No. 84,666. (No model.)



Claim.—1. A device of the class described comprising a metallic disk having a diametrical slot extending from its upper edge to a point near to its lower edge and having an ear at its lower edge bent outwardly at right angles to the face of the disk, a plate disposed transversely of the under side of the tongue and having spaced perforations, and a U-shaped clip having its legs engaged through the perforations and provided with nuts to prevent withdrawal thereof.

2. The combination with an axletree and spindle, of a wheel disposed upon the spindle and having a hub-band projecting from the inner end thereof, the axletree being higher than the band and having a slot in its end face in which the band is received, a metallic disk disposed in the end of the band and having a tongue cut therefrom and a resultant diametrical slot in which the axletree is snugly received, said ear being bent outwardly from the face of the disk, a plate disposed against the under side of the ear and provided with laterally-spaced perforations, and a clip disposed over the axletree and having its legs engaged through the perforations of the plate, said legs having nuts engaged therewith to prevent withdrawal thereof.

706,216. **ROLL-HOLDING CAMERA.** JOHN G. BROWNING, Fairfield, Iowa. Filed Mar. 31, 1902. Serial No. 100,726. (No model.)

Claim.—1. In a roll-holding camera, a spool-holding device adapted to receive spools of different lengths in combination with means adjustable within the body of the camera for shielding a part of the field of exposure of the camera.

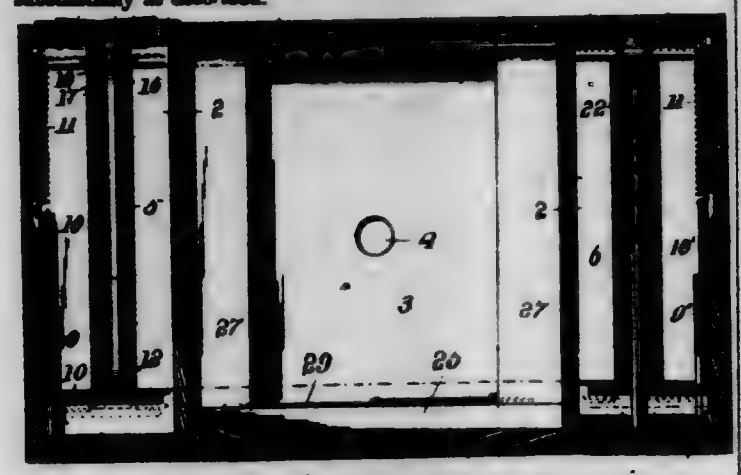
2. In a roll-holding camera, a shield located at each end of the field of exposure and adapted to be adjusted to the front of the film or to the rear thereof, and means for holding said shields in their different places of adjustment.

3. In a roll-holding camera, a roll-holding device comprising a suitably-journaled spindle provided with a shoulder and a spring-actuated bracket adapted to press a spool against the shoulder of the spindle for one size spool and adapted to press a spool against the bearing of the spindle with the shoulder of said spindle at its rear for a larger-size spool, substantially as described.

4. In a roll-holding camera, a spool-holding device comprising a rotatable thumb-nut, a pawl-and-ratchet mechanism mounted thereon, a flange on the thumb-nut to fit the spool-slot for a large-size spool, a spring-actuated bracket having a trunnion on which a spool may be mounted, and a removable hub having a socket to fit over the flange on the thumb-nut and a flange to fit in the spool-slot for a small-size spool, substantially as described.

5. In a roll-holding camera, a spool-holding device comprising a suitably-journaled spindle provided with a shoulder and a spring-actuated bracket adapted to press a spool against the shoulder of the spindle for

one size spool and adapted to press a spool against the bearing of the spindle with the shoulder of said spindle at its rear for a larger-size spool, a rotatable thumb-nut, a pawl-and-ratchet mechanism mounted thereon, a flange on the thumb-nut, to fit the spool-slot for a large-size spool, a spring-actuated bracket having a trunnion on which a spool may be mounted, and a removable hub having a socket to fit over the flange on the thumb-nut and a flange to fit in the spool-slot for a small-size spool, substantially as described.

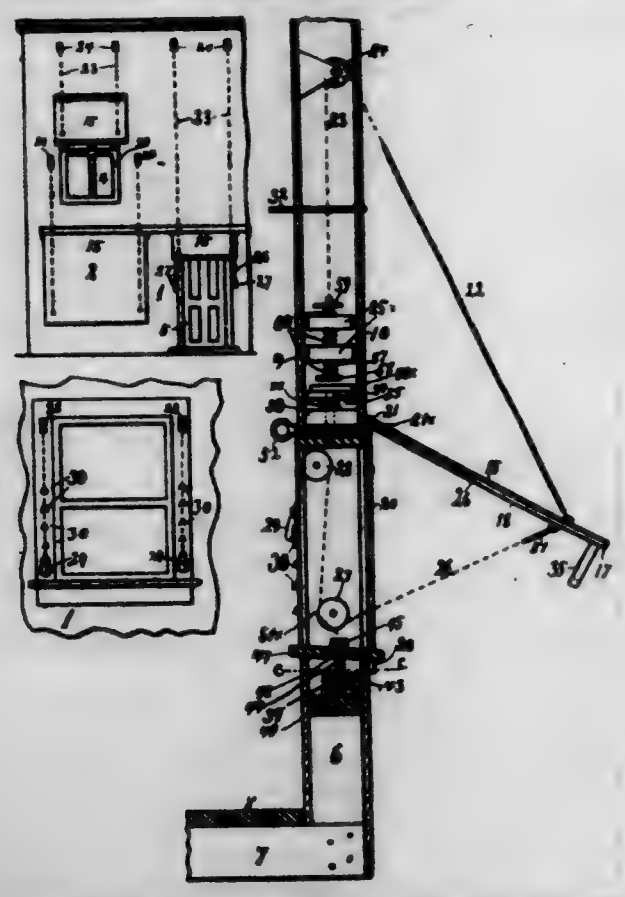


6. In a roll-holding camera, means adjustable within the body thereof adapted to be placed in front of the film or to the rear of said film whereby a full-sized exposure may be made or a reduced-sized exposure made, substantially as described.

7. In a roll-holding camera, a shield located at each end of the field of exposure and adapted to be adjusted to the front of the film or to the rear thereof.

8. In a roll-holding camera a shield mounted in slots in the frame of the camera at each end of the field of exposure thereof said slots being wider at their outer ends, the shields being adapted to lie in the front of the film when in the wider portions of the slots and to lie behind the film when in the narrow portions of said slots.

706,217. WINDOW-SHUTTER. John G. Bush, Alma, Wis. Filed Oct. 24, 1901. Serial No. 79,731. (No model.)



Claim.—1. The combination with a counterbalanced window-shutter hinged above the window and having locking-hooks near its free corners adapted to engage a locking mechanism in the wall, of a locking mechanism located in the wall or window-frame and having catches adapted to engage said hooks, said catches being connected together and to an unlocking lever or handle within easy reach upon the window-sill, and springs for throwing said hooks and catches into engagement.

2. In a shutter for doors or windows, the combination with a shutter hinged above the door or window to fold downward upon the same; sheaves in the wall above the shutter, chains or ropes extending from the shutter over the top of said sheaves, weights secured to the inner ends of said chains to raise the shutter, and stops above and below the weights, substantially as and for the purpose set forth.

3. The combination with a shutter hinged above a window or door, of weights counterbalancing and raising the shutter, sheaves arranged above the shutter, ropes or chains passed over the sheaves and secured to the weights, and to the shutter by means of rods 22 for steadying the shutter when raised.

4. The combination with a shutter for windows and doors the same being hinged at its upper edge, of ropes or a rope or chain passed over a sheave and having one end secured to the shutter to be raised, and at the other end a weight adapted to raise the shutter, a stop to take the blow of the weight, said stop being lined on its top with a cushion and consisting of two members with a spring interposed between them, and said weight consisting of a vertical rod secured to the rope, and a series of weight-sections and springs interposed between them on the rod.

5. The combination with a shutter hinged above a door or window of a counterbalancing and raising weight and a stop for same to fall upon, said weight consisting of a vertical rod and a series of weight-sections and intermediate coil-springs, and a plate secured on the lower end of the rod and a spring between it and the lowest weight-section.

6. In a raising and falling window-shutter, the combination with the counterbalancing-rope 23 and its shutter-raising weight 25, of stops above and below the weight to regulate automatic tilting of the shutter when snow accumulates on it.

7. The combination with an upwardly-folding, weight-controlled shutter of the closing cord or cords 26 secured to its under side and having its inner end within the building and provided with a small weight or handhold 29, the catches 30 adapted to hold the weight at various heights, and the sheaves 27 28 guiding said rope.

8. The combination with an upwardly-folding, weight-controlled shutter of the closing cords or cord 26 secured to its under side and having its inner end within the building and provided with a small weight or handhold 29, the catches 30 adapted to hold the weight at various heights, the sheaves 27 28 guiding said rope, and the short rods 51 at the outer end of the rope.

9. The combination with the locking-hooks of a downwardly-folding window-shutter, of a locking device located in the wall below the window-sill and having catches adapted to engage the hooks, a flexible or spring rod 43 connecting said catches and adapted to retract both of them when the rod is sprung out of line, means for springing the rod out of line and stops to control the motion of the catches.

10. The combination with the locking-hooks of a downwardly-falling window-shutter of a locking device located in the wall below the window-sill, and having catches adapted to engage the hooks, a flexible or spring rod 43 connecting said catches and adapted to retract both of them when the rod is sprung out of line, means for springing the rod out of line and stops to control the motion of the catches, and the rest 49 for supporting the rod in its normal position.

706,218. ELECTRIC SIGNALING SYSTEM AND APPARATUS USED THEREIN. Robert G. Callum, Washington, D. C. Filed Jan. 9, 1902. Serial No. 89,015. (No model.)

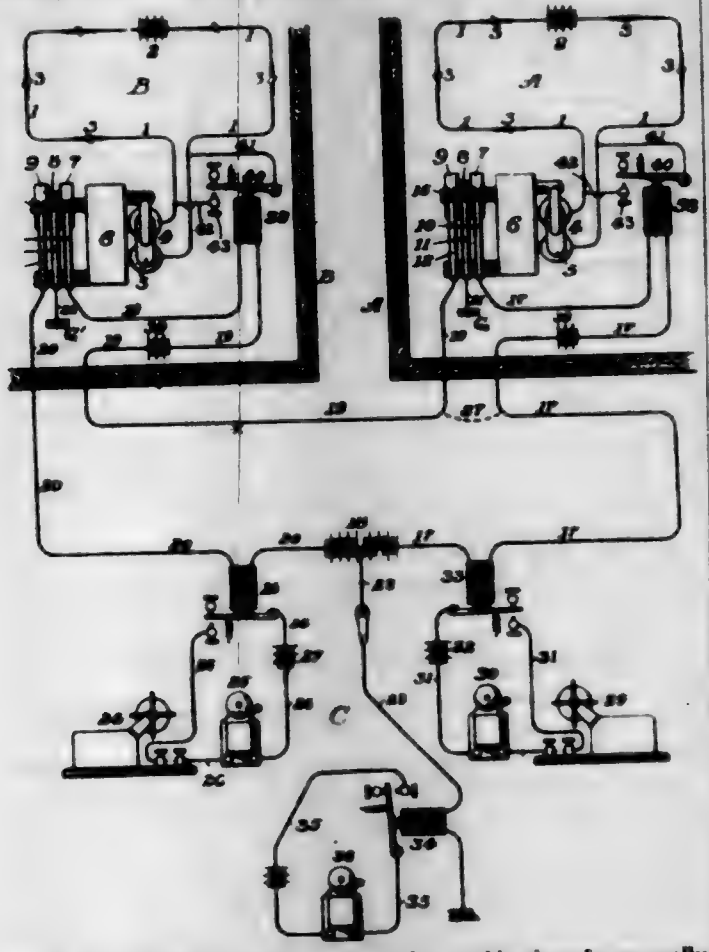
Claim.—1. In an electric signaling system, the combination of a normally closed metallic circuit connecting the place to be signaled from with a signal-receiving station, a ground connection in said circuit dividing the batteries thereof, one or more signaling instruments within said circuit adapted to automatically ground said circuit and transmit signals thereover at both sides of such ground, and means for indicating an increase of current through the first-mentioned ground connection, substantially as and for the purposes specified.

2. In an electric signaling system, the combination of a normally closed metallic circuit connecting the place to be signaled from with a signal-receiving station, a signaling instrument adapted to automatically ground said circuit and transmit a signal thereover to said receiving-station, and means for causing the operation of said instrument when the latter is looped out of said main circuit, substantially as described.

3. In an electric signaling system, the combination of a normally closed metallic circuit connecting the place to be signaled from with a signal-receiving station, a ground connection dividing the batteries of said circuit at said receiving-station, signal receiving or recording instruments controlled by the main-line current at each side of said ground connection, a signaling instrument adapted to automatically ground said circuit and transmit signals over the two earth-circuits thus established, an electromagnet within a local circuit for controlling the operation of said instrument, and means for causing said magnet to operate said instrument when the latter is cut out of the main circuit, substantially as described.

4. In an electric signaling system, the combination of a normally

closed metallic circuit connecting the place to be signaled from with a signal-receiving station, a ground connection dividing the batteries of said circuit at said receiving-station, signal receiving or recording instruments controlled by the main line at each side of said ground connection, a signaling instrument adapted to automatically ground said circuit and transmit signals over the two ground-circuits thus established, an electromagnet within a local circuit controlling the operation of said instrument, a relay within the main circuit adapted to short-circuit said magnet when the resistance of the main line is removed from said relay, substantially as and for the purposes specified.



5. In an electric signaling system, the combination of a normally closed metallic circuit connecting the place to be signaled from with a signal-receiving station, a ground connection in said circuit dividing the batteries thereof, separate signal-receiving instruments controlled by said circuit at both sides of said ground connection, a signaling instrument, a normally open relay in said ground connection for controlling said instrument, and a signaling instrument at the place to be signaled from adapted to automatically ground said circuit and transmit a signal over the two earth-circuits thus established, substantially as and for the purposes specified.

6. In an electric signaling instrument, the combination of a circuit-breaking wheel or wheels, mechanism for rotating said wheel or wheels, a tripping device for said mechanism, an electromagnet for operating said tripping device, and means operative only after said tripping device has been first operated by said electromagnet for causing said wheels to be revolved at predetermined intervals, substantially as described.

7. In an electric signaling instrument, the combination of a circuit-breaking wheel or wheels, mechanism for rotating said wheels, a tripping device for said mechanism, an electromagnet for operating said device, mechanism for operating said device independently of the operation of said electromagnet, and means for preventing the operation of said last-mentioned mechanism until after said tripping device has been first operated by said magnet, substantially as described.

8. In an electric signaling instrument, the combination of a circuit-breaking wheel or wheels driven by windable mechanism, a tripping device for said mechanism, an electromagnet for operating said device, clock mechanism for operating said tripping device at predetermined intervals, and means whereby said clock mechanism will be prevented from operating said tripping device until after said device has been first operated by said electromagnet, substantially as described.

9. In an electric signaling instrument, the combination of a circuit-breaking wheel or wheels driven by windable mechanism, a tripping device for said mechanism, an electromagnet for causing the operation of said device, clock mechanism for operating said tripping device at predetermined intervals, and means for holding said clock mechanism in check controlled by said electromagnet, substantially as described.

10. In an electric signaling instrument, the combination of a circuit-breaking wheel or wheels, mechanism for rotating said wheel or wheels, a tripping device for said mechanism, clock mechanism for operating said device at predetermined intervals, a tripping device for said clock mechanism, and an electromagnet for simultaneously operating both tripping devices, substantially as described.

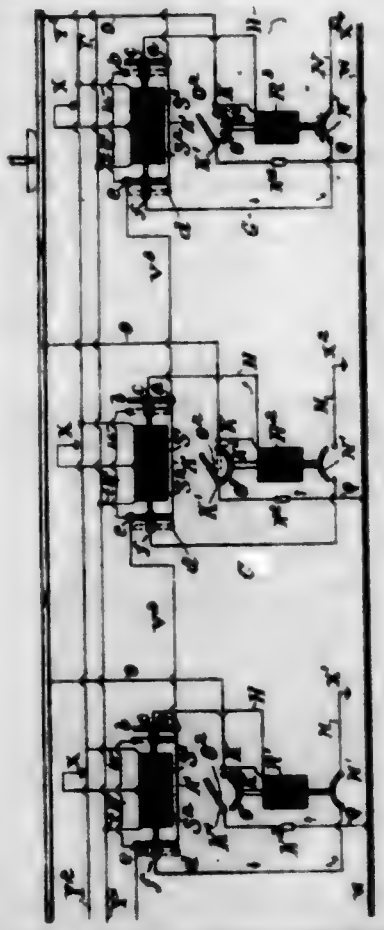
11. In an electric signaling instrument, the combination of a circuit-breaking wheel or wheels, mechanism for driving said wheel or wheels, a tripping device for said mechanism, clock mechanism for operating said device at predetermined intervals, a device for holding said clock mechanism in check adapted when released to give a starting impulse to said clock mechanism, and an electromagnet for holding said device in its operative position, substantially as described.

12. In an electric signaling instrument, the combination of a circuit-breaking wheel or wheels, mechanism for driving said wheel or wheels a tripping device for said mechanism, clock mechanism for operating said device at predetermined intervals, a device for holding said clock mechanism in check adapted when released to give a starting impulse to said clock mechanism, and an electromagnet for controlling the operation of said device, substantially as described.

13. In an electric signaling instrument the combination of a circuit-breaking wheel or wheels, mechanism for driving said wheel or wheels, a detent for normally holding said mechanism in check which when moved for releasing said mechanism will again check the same after the latter has revolved said wheel or wheels a predetermined number of revolutions, an electromagnet for moving said detent, a clock-movement for moving said detent at predetermined intervals, and means for preventing said clock-movement and its connecting mechanism from interfering with a movement of said detent by said magnet, substantially as described.

14. In an electric signaling instrument, the combination of a circuit-breaking wheel or wheels, mechanism for driving said wheel or wheels, a detent for normally holding said mechanism in check which when moved for releasing said mechanism will again check the same after the latter has revolved said wheel or wheels a predetermined number of revolutions, an electromagnet for moving said detent, a clock-movement for moving said detent at predetermined intervals, and means controlled by said magnet for normally holding said clock-movement in check, substantially as described.

706,219. METHOD OF OPERATING ELECTRIC RAILWAYS. CHARLES R. CAMPBELL, New York, N. Y. Filed May 6, 1902. Serial No. 106,170. (No model.)

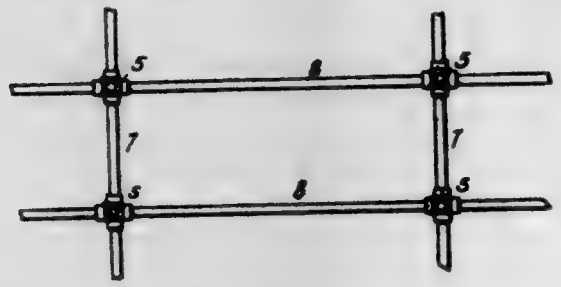


Claim.—1. The method of operating electrically-driven cars in either direction, consisting in leading a power-current along the line, diverting a portion of the power-current to form a divisionary shunt controlled by switches for use in fixing the direction the cars shall take, going or coming, leading two supplementary currents along the line independent of but paralleling the power-current for momentarily energizing one or

the other of the double solenoids, providing a changeable route for such divisionary, and controlling by switches the grounding of said shunt independently toward the right or left.

2. The method of electrically operating motor-cars in either direction over the same track, consisting in leading a power-current along the line, diverting a portion of the power-current to form a divisionary or shunt for use in fixing the direction the cars shall take, leading two supplementary currents along the line independently of but paralleling the power-current for momentarily energizing one or the other of the double solenoids, providing a changeable path for such divisionary current controlled by switches, grounding said shunt independently through its own switch toward the right or left, whereby the route of such divisionary to ground forward or backward determines the direction the car shall take, as set forth.

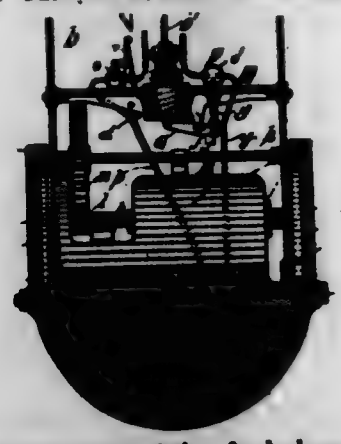
706,220. WIRE-FENCE FASTENING-CLIP. Frank Canfield, Denver, Colo., assignor to the Western Wire Fence Company, Denver, Colo. Filed Nov. 9, 1901. Serial No. 81,736. (No model.)



Claim.—1. A wire-fence clip composed of two coöperating members, each having a central part and four radial projections, the central part having an opening, the projections of both members being provided with grooves, the members being arranged on opposite sides of the wire and stay, the grooves of the projections forming seats for the parts to be connected, and the central parts of the members being adapted to receive the opposite bends of the two parts at their intersection, the projections of the two members having faces which are oppositely located when the parts are assembled, one of the members having arms located intermediate its projections, which arms are adapted to embrace and clinch upon the other member, the outer extremities of these arms being bent into the opening of the last-named member whereby the two parts are securely held together.

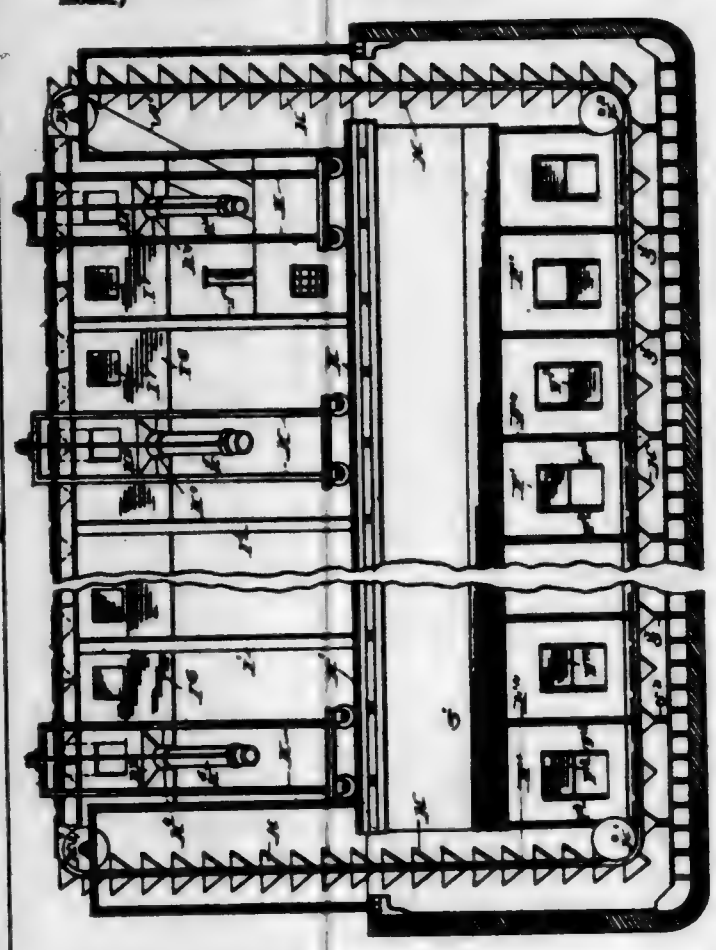
2. A wire-fence clip composed of two coöperating members, each member having a central part and four radial projections, the central part of one member having an opening, and the projections of each member having grooves leading outwardly from the central portion, the two members when the parts are assembled being arranged to embrace the wire and clip from opposite sides, and provided with oppositely-located faces, one of the said members having arms located between its projections, which arms embrace and clinch upon the central part of the other member, the outer extremities of the said arms being bent into the opening of the last-named member to increase their holding capacity.

706,221. CLAM FOR DREDGES. Ephraim Chagnette, New Rochelle, N. Y. Filed Jan. 10, 1902. Serial No. 89,103. (No model.)



Claim.—The above-described clam for dredges which consists of an electric motor mounted upon a suitable frame, a shell inclosing said motor and composed of two hinged portions pivoted to said frame, one of said portions having an outside segmental rack and the other an inside segmental rack, a pinion driven by said motor and engaging both said racks and suitable circuit-closers mounted upon said clam whereby a direct or reverse current may be automatically transmitted to said motor to open or close said clam when required.

706,222. APPARATUS FOR UNLOADING COAL. Charles D. Day, Baltimore, Md. Filed Mar. 26, 1902. Serial No. 99,967. (No model.)



Claim.—1. An apparatus for unloading coal comprising a reservoir, a runway mounted thereabove, an endless, grouped bucket conveyer passing from the bottom of the reservoir along the runway, means for simultaneously discharging the buckets of several groups of buckets at a predetermined but changeable group of points along the runway, and a number of movable carriages carrying chutes placeable at this group of points to receive and transfer the discharge from the buckets, substantially as described.

2. An apparatus for unloading coal comprising a reservoir, a runway mounted thereabove, an endless, grouped bucket conveyer passing from the bottom of the reservoir along the runway, differential tilting devices at a preselected but changeable group of points along the runway for discharging different groups of buckets at these points, and a number of movable carriages carrying chutes placeable at this group of points to receive and transfer the discharge from the buckets, substantially as described.

3. An apparatus for unloading coal comprising a reservoir, a runway mounted thereabove, an endless grouped bucket conveyer passing from the bottom of the reservoir along the runway, stops fixed in different positions on different groups of buckets, trips at a preselected but changeable group of points along the runway to coöperate with the stops each to tilt and discharge a given group of buckets, and a number of movable carriages carrying chutes placeable at this group of points to receive and transfer the discharge from the buckets, substantially as described.

4. An apparatus for unloading coal comprising a reservoir with inclined bottoms and a tunnel having gates coöperating therewith, a runway mounted above the reservoir, and endless, grouped bucket conveyer passing from below the inclined bottoms of the reservoir along the runway, means for simultaneously discharging the buckets of several groups of buckets at a preselected but changeable group of points along the runway, and a number of movable carriages carrying chutes placeable at this group of points to receive and transfer the discharge from the buckets, substantially as described.

5. An apparatus for unloading coal comprising a reservoir, a runway mounted thereabove, inclines and a series of gates below the runway, an endless grouped bucket conveyer passing from the bottom of the reservoir along the runway, means for simultaneously discharging the buckets of several group of buckets at a preselected but changeable group of points along the runway so that it may pass down the inclines and through such gates as are open, and a number of movable carriages carrying chutes placeable in front of the group of open gates, substantially as described.

6. An apparatus for unloading coal comprising a reservoir, a runway mounted thereon comprising a pair of angle-irons having tracks, an endless grouped bucket conveyer passing from the bottom of the reservoir along the runway, stops fixed in different positions on different groups of

buckets, trips passing through apertures in the angle-irons at a preselected but changeable group of points along the runway to coöperate with the stops each to tilt and discharge a given group of buckets, and a number of movable carriages carrying chutes placeable at this group of points to receive and transfer the discharge from the buckets, substantially as described.

7. An apparatus for unloading coal comprising a reservoir, a runway mounted thereabove, an endless grouped bucket conveyer passing from the bottom of the reservoir along the runway, means for simultaneously discharging the buckets of several groups of buckets at a preselected but changeable group of points along the runway, and a number of movable carriages carrying vertically-adjustable chutes placeable at this group of points to receive and transfer the discharge from the buckets, substantially as described.

8. An apparatus for unloading coal comprising a barge, a runway mounted thereabove, and endless, grouped bucket conveyer passing from the bottom of the barge along the runway and back to the bottom of the barge, means for simultaneously tilting and thus discharging the tiltable buckets of several groups of buckets at predetermined but changeable groups of points along the runway, and a number of movable carriages carrying chutes mounted on the barge and placeable at a given group of points to receive and transfer the discharge from the buckets, substantially as described.

9. An apparatus for unloading coal comprising a barge, a runway mounted thereabove, and endless grouped bucket conveyer passing along the bottom of the barge and thence along the runway and back to the bottom of the barge, stops fixed in different positions on different groups of buckets, trips at a preselected but changeable group of points along the runway to coöperate with the stops, each to tilt and thus discharge a given group of buckets, and a number of movable carriages carrying chutes mounted on the barge and placeable at this group of points to receive and transfer the discharge from the buckets, substantially as described.

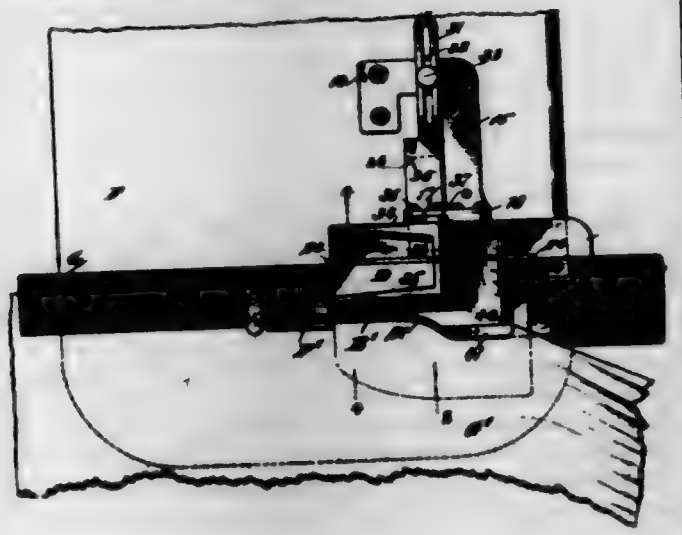
10. An apparatus for unloading coal comprising a barge, a runway mounted thereabove, inclines and a series of gates below the runway, an endless, grouped bucket conveyer passing along the bottom of the barge and thence along the runway back to the bottom of the barge, means for simultaneously tilting and thus discharging the buckets of several groups of buckets at a preselected but changeable group of points along the runway so that it may pass down the incline and through such gates as are open, and a number of movable carriages carrying chutes mounted on the barge and placeable in front of the group of open gates to receive and transfer the discharge from the buckets, substantially as described.

11. An apparatus for unloading coal comprising a barge, a runway mounted thereabove, and endless grouped bucket conveyer passing along the bottom of the barge up to and along the runway and back to the bottom of the barge, means for simultaneously tilting and thus discharging the buckets of several groups of buckets at a preselected but changeable group of points along the runway, and a number of movable carriages carrying chutes mounted on the barge and placeable at this group of points to receive and transfer the discharge from the buckets, substantially as described.

12. An apparatus for unloading coal comprising an endless grouped bucket conveyer, means for simultaneously discharging the buckets of several groups of buckets at a preselected but changeable group of points and a number of movable carriages carrying chutes placeable at this group of points to receive and transfer the discharge from the buckets, substantially as described.

706,228. HEMMING ATTACHMENT FOR SEWING-MACHINES.

THOMAS F. DEMMON, Brooklyn, N. Y. Filed June 22, 1901. Serial No. 65,630. (No model.)



Claim.—1. A sewing-machine attachment, comprising a base-plate, adapted for attachment to a sewing-machine and having transverse guideways formed in its under face, an upper plate carried by the support for the base-plate, each plate being provided with a folding-scroll, a gage-plate adapted to be adjusted between the scroll-carrying plates to regulate the width of a hem, an adjusting supporting-bar for the gage-plate and movable in the guideways on the under face of the base-plate, means for holding the supporting-bar in position in the guideways and a hem guide-bar mounted to travel on the upper face of the base-plate, and connected with the supporting-bar for the gage-plate, as set forth.

2. In a sewing-machine attachment a stationary lower or base plate having means for attachment to a sewing-machine, one end portion of said base-plate being elevated above the other, guideways formed on the under face of the elevated portion of the base-plate, an upper stationary plate carried by the support for the base-plate, folding-scrolls carried by the upper plate and base-plate, the two scrolls having position one above the other, a gage-plate for a hem adjustable transversely between the upper and lower plates, a hem guide-bar mounted on the base-plate, a supporting-bar to which the gage-plate is secured, the said supporting-bar being adjustable in the guideways on the under face of the base-plate, and means for holding the supporting-bar in position in the guideways, the hem guide-bar being adjustably connected with the said supporting-bar, as described.

3. In a sewing-machine attachment, the combination with a stationary lower or base plate having guideways formed on its under face, a bearing-plate connected with the inner longitudinal edge of the base-plate and extending above the same, an upper stationary plate having an upward extension secured to the bearing-plate, and corresponding turning-scrolls carried by the base-plate and the upper plate, of a gage-plate adjustable to and from the scrolls to form a wide or a narrow hem, a supporting-bar for the gage-plate adjustable in the guideways on the under face of the base-plate, and buttons secured respectively to the base-plate and the lower projecting portion of the bearing-plate and arranged to hold the supporting-bar in position in the said guideways, as set forth.

4. A sewing-machine attachment, comprising an upper plate and a lower or base plate each provided with a folding-scroll, one end portion of the base-plate being elevated above the other, longitudinal brace-bars on the under face of the elevated portion of the base-plate and provided with recesses forming guideways, a gage-plate adjustable between the scroll-carrying plates, a supporting-bar for the gage-plate adjustable in the said guideways transversely of the base-plate, and buttons for holding the said bar in position in the guideways, as set forth.

5. A sewing-machine attachment comprising two plates each provided with a scroll having a plate curved transversely and forming a portion of the scroll, the curved plate extending longitudinally of the scrolls and adjustable transversely, and a gage-plate having movement between the scroll-carrying plates and adapted to regulate the width of a hem, as described.

6. In a sewing-machine attachment, a lower or base plate, a scroll carried by said base-plate, a transversely-curved plate fitted longitudinally in the scroll and adjustable transversely of the same, an upper plate provided with a similar scroll and adjustable curved plate, oppositely arranged, a gage-plate adjustable between the scroll-carrying plates to regulate the width of a hem, and means for adjusting the gage-plate, substantially as described.

7. A sewing-machine attachment, comprising a lower or base plate having a guideway in its under face, a tongue connected with the base-plate and having an L extension at its inner end provided with apertures for securing the attachment to the sewing-machine, a turning-scroll on said base-plate, an upper stationary plate having a scale at its forward end, a turning-scroll forming a portion of said upper plate, a gage-plate mounted to slide between the upper and lower plates, a supporting-bar secured to the outer edge of the gage-plate and adjustable in the guideway in the under face of the lower or base plate, and a hem guide-bar mounted on the base-plate and provided with a shank extending longitudinally of the tongue of the base-plate, the said shank being attached to the inner end of the supporting-bar secured to the gage-plate, and having an extension arranged for adjustable connection with the L extension of the tongue of the base-plate, as set forth.

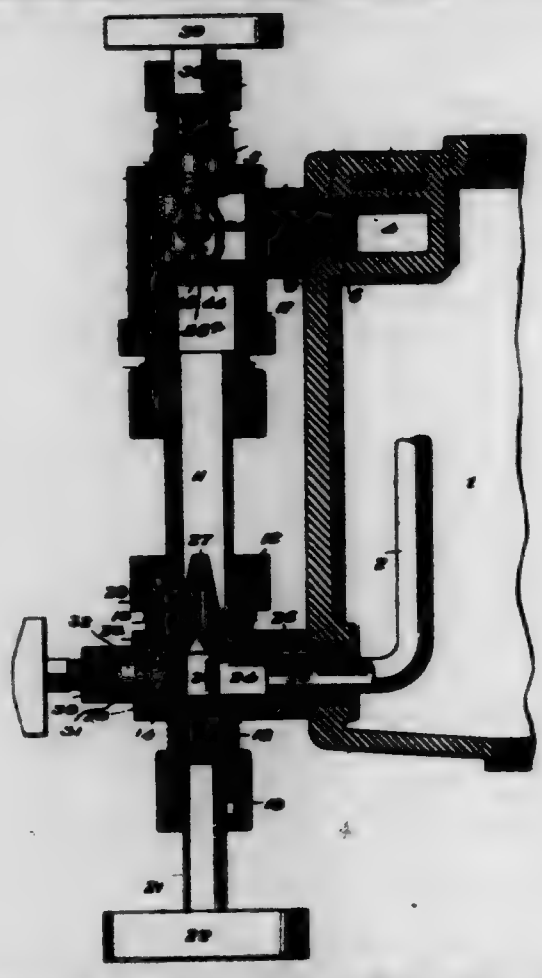
8. A sewing-machine attachment, comprising a lower or base plate wider at one end portion than the other, the outer edge of the narrow portion of the base-plate being downwardly depressed and then curved upward and inward at the extreme outer edge forming a scroll, a transversely-curved plate adjustably fitted in the depressed portion of the scroll, an upper plate provided with a similar scroll and adjustable curved plate oppositely arranged, and a gage-plate adjustable between the scroll-carrying plates and adapted to regulate the width of a hem, as described.

9. In a sewing-machine attachment a lower or base plate provided with a scroll having a fixed member and a member adjustable relative to the fixed member and comprising a transversely-curved plate fitted in the

fixed member and having a shank for adjustable connection with the base-plate, and an upper plate provided with a similar scroll having its movable member adjustably connected with said upper plate, as set forth.

10. A sewing-machine attachment comprising an upper stationary plate having a scale formed at its forward end, a stationary lower or base plate, folding-scrolls carried by said plates and arranged one above the other, a gage-plate adjustable between the scrolls and provided with an extension or finger at its forward end portion to serve as an extra guide for the material to be formed into a hem, means for guiding the movement of the gage-plate and securing the same in adjusted position, and a guide-bar for the hem adjustable toward and from the inner longitudinal edge of the gage-plate, and movable with said gage-plate, substantially as described.

706,224. LUBRICATOR. FRANK W. EDWARDS, Logansport, Ind. Filed Oct. 30, 1901. Serial No. 80,569. (No model.)



Claim.—1. In a lubricator, a feed-arm with a chamber, a cage fitted to a seat around an opening in the bottom of said chamber and having a smaller port in its bottom, a valve fitted to said port in said cage and movable within the cage independently thereof, and means movable independently of the cage and valve for seating the valve and cage together or allowing them to move independently of each other.

2. In a lubricator, a feed-arm having a chamber with opening, a cage fitted to said opening and having a small port, a valve movable within the cage and fitted to the opening therein, and means independent of and engaging said smaller valve and movable within the cage for closing both of said ports.

3. In a lubricator, a feed-arm having a diaphragm with port, a cage seated at said port and having a smaller port, a valve fitted to said port in the cage and having a stem, a stem disconnected from the cage and having tubular portions to receive the stem of the said valve and means to engage the cage, and means constructed to raise and lower the stem.

4. In a lubricator, a feed-arm having a diaphragm with port, a cage fitted to said port and having openings in its side walls and a valve-port, a valve having a stem and fitted to the port in the cage, a stem independent of the cage and having tubular lower end to receive the stem of the valve, and a lateral projection on said stem to engage and raise the cage and valve.

5. In a lubricator, a feed-arm having a chamber and diaphragm with port, a cage adapted to be seated to said port and having a smaller port in its lower portion, and openings above the same, a valve fitted to the port in the cage, a stem with tubular lower end movable independently of the cage, said valve being independently movable and having a stem fitting said tubular portion, and said lower end of the tubular stem being adapted to engage said valve for seating the valve and cage together or allowing them to move independently of each other, as set forth.

6. In a lubricator, an arm having a diaphragm with port, a cage having a bottom portion fitted to said port and having a smaller port in its bottom, a valve movable independently of the cage and fitted to said port therein, a stem independent of said valve and cage and movable within the latter and having a portion to receive the stem of said valve, means for engaging said stem with the valve to hold the latter to its seat, and means for engaging the cage to raise the same to move the cage and valve simultaneously, as set forth.

706,225. COMBINED CANE AND FISHPOLE. JOHN A. BERGLUND, Minneapolis, Minn., assignor of one-fourth to Nels A. Johnson, Murdock, Minn. Filed Nov. 26, 1901. Serial No. 83,663. (No model.)

Claim.—1. A combined cane and fishing-pole, comprising two or more telescoping sections, a hollow handle wherein that portion of the line intermediate to its ends may be folded, means for securing one end of the line near said handle and means for securing the opposite end in the outer section, substantially as described.

2. A combined cane and fishing-pole, comprising two or more telescoping sections, a hollow handle wherein that portion of the line intermediate to its ends may be folded, one end of the line extending through a hole in said handle and provided with a button, and the opposite end of the line extending through said telescoping sections, and provided with a head or cap at the outer end of the outer section, substantially as described.

3. A combined cane and fishing-pole, comprising two or more telescoping sections, a hollow handle provided at right angles to said sections and having a hinged cover and wherein a fishing-line may be folded, one end of said line being provided with a button and extending through a hole near the folded portion of said line and the opposite end of the line being provided with a head or cap fitting into the end of the outer section.

4. A combined cane and fishing-pole, comprising two or more telescoping sections, a hollow handle wherein the line may be folded, means for securing one end of the line in the outer section or tip of the pole, a roller provided near the folded portion of said line and around which the other end of the line is passed, and a button provided outside of said hand and connected to said last-named end.

5. A combined cane and fishing-pole, comprising two or more telescoping sections provided with slots or notches, spring-catches adapted to enter said slots and lock said sections when extended, a hollow handle wherein the portion of the line intermediate to its ends may be folded one end of said line extending outside said handle and adapted to be connected to a reel and the other end of the line being secured in the outer or tip section.

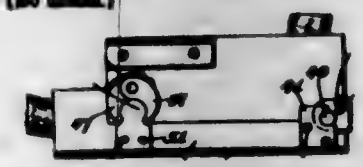
6. A combined cane and fishing-pole, comprising two or more telescoping sections provided with a hollow handle adapted to receive a folded fishing-line, a ring provided in the open end of the outer section and to which one end of the line is attached, and a button or cap provided near said handle and to which the opposite end of the line is connected, substantially as described.

7. A combined cane and fishing-pole, comprising two or more telescoping sections, means for locking said sections in their extended position, and for rendering the outer section capable of adjustment to different lengths, a hollow handle provided on the inner section, said handle being provided with a cover and adapted to contain a fishing-line, substantially as described.

8. A combined cane and fishing-pole, comprising two or more telescoping sections, means for locking them in their extended position, a hollow handle portion wherein the line intermediate to its ends may be folded, and means for securing the ends of said line at or near the opposite ends of the pole.

9. A combined cane and fishing-pole, comprising two or more telescoping sections, means for locking said sections when extended, a hollow handle portion wherein the line intermediate to its ends may be folded, one end of said line extending outside said handle portion and adapted to be connected to the reel, and the outer end of the line being secured in the outer or tip section.

706,226. ELECTRIC TRAIN-CONNECTOR. CHARLES E. PELT and DANIEL A. KINSARK, Chicago, Ill. Filed Nov. 29, 1901. Serial No. 83,965. (No model.)



Claim.—1. In an electric train-connector the combination of a female member, a male member insertible transversely therein and means for locking said members together, substantially as set forth.

2. In an electric train-connector the combination of a female member, a male member insertible transversely therein and spring-actuated locking means for holding said members together, substantially as set forth.

3. In an electric train-connector the combination of a female member, a male member, a hinge connection for said members comprising two parts, male and female, located on said members respectively, and means for holding said members against accidental turning on said hinge, substantially as set forth.

4. In an electric train-connector the combination of a female member, a male member, a hinge connection for said members comprising two parts, male and female, located on said members respectively, the female member of said hinge having an open side for the transverse insertion of the male hinge member, and means for holding said connector members against accidental turning on said hinge, substantially as set forth.

5. In an electric train-connector the combination of a female member, a male member, a hinge connection for said members comprising two parts, male and female, located on said members respectively and a clutch for holding said members against accidental turning on said hinge, substantially as set forth.

6. In an electric train-connector the combination of a female member, a male member, a hinge connection for said members comprising two parts, male and female, located on said members respectively at one end thereof, and means located at the other end of the connector for holding the members thereof against accidental turning on said hinge, substantially as set forth.

7. In an electric train-connector the combination of a female member, a male member, a hinge connection for said members comprising two parts, male and female, located on said members respectively, the female part having an open side for the transverse insertion of the male part of said hinge, and a pivoted clutch for holding said members against accidental turning on said hinge, substantially as set forth.

8. In an electric train-connector the combination of a female member, a male member, a hinge connection for said members comprising two parts, male and female, located on said members respectively, the female part of said hinge having an open side for the transverse insertion of the male part thereof, and a pivoted clutch comprising two independently-movable spring-actuated members for locking the first said members against accidental turning on said hinge, substantially as set forth.

9. In an electric train-connector the combination of male and female members hinged together hook fashion and a clutch for holding them from opening or swinging on their hinge, substantially as set forth.

10. In an electric train-connector the combination of male and female members detachably hinged together hook fashion and separable both transversely and longitudinally, and means for holding them from accidental turning on their hinge, substantially as set forth.

11. In an electric train-connector the combination of male and female members hinged together hook fashion and having engageable inclines for forcing them transversely when subjected to longitudinal strain, substantially as set forth.

12. In an electric train-connector the combination of a female member having an incline at one end and a hinge member at the other end, and a male member having an incline at one end and a hinge member at the other end and adapted to be inserted between and engage with said first incline and hinge member respectively, substantially as set forth.

13. In an electric train-connector the combination of a female member having an incline at one end and a hinge member at the other end, a male member having an incline at one end and a hinge member at the other end adapted to be inserted between and engage with said first incline and hinge member respectively, and a clutch for holding said male and female members against accidental turning on their hinge, substantially as set forth.

14. In an electric train-connector the combination of male and female members engageable with each other in a transverse direction, means for yieldingly locking said members against transverse movement, and means for forcing said members transversely against the action of said locking means, when one of them is subjected to longitudinal strain, substantially as set forth.

15. In an electric train-connector the combination of a female member provided with an internal incline, a male member having an incline adapted to be engaged with said first incline, a hinge located at one end of said train-connector and comprising disengageable male and female parts, and a clutch located at the opposite end of said connector and comprising male and female parts located on said male and female members for holding the latter from accidental turning on said hinge, substantially as set forth.

16. In a train-connector the combination of a male and a female member one of which comprises an angular head, each angle of which has a perforation or socket therein, and an electric conductor-lug having means adapted to be inserted in and secured to either of said sockets, substantially as set forth.

17. In an electric train-connector the combination of male and female members one of which comprises an angular part, and an electric conductor-lug, said lug and each angle of said angular part having engageable fastening means for attaching the lug thereto, substantially as set forth.

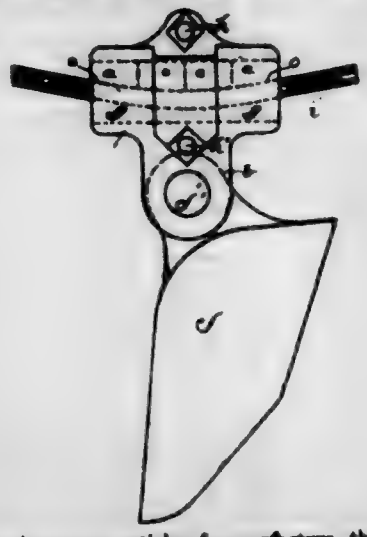
18. In an electric train-connector the combination of male and female members one of which is provided with apertures in the side and the end thereof and an angular part with its angles opposed to said apertures respectively, and an electric conductor-lug adapted to be inserted through either of said apertures and to connect with either of said angles, substantially as set forth.

19. In an electric train-connector the combination of male and female members one of which comprises an angular part arranged so that one of the angles thereof will be opposed to the adjacent end of the member, an electric conductor-lug adapted to be inserted through either said side or end, and means whereby said lug may be attached to either of said angles, substantially as set forth.

20. In an electric train-connector the combination of male and female members, a plurality of electric conductors connected with each of said members, a plurality of electric contacts carried by each of said members and connecting with said conductors respectively, and a jumper comprising a flat blade slidable between two of said contacts on one of said members and an exterior operating-handle connecting with said blade, substantially as set forth.

21. In an electric train-connector the combination of male and female members, a plurality of electric conductors for said members, respectively, a plurality of contacts carried by said members for said conductors respectively, two flexible fingers connecting two of said contacts together on one of said members, a longitudinally-slidable blade carried by one of said members and adapted to slide between said fingers, and a handle connected to and insulated from said blade and slidably mounted in one of said members, substantially as set forth.

706,227. SUSPENSION-CLAMP. JOHN B. FLETCHER, Dayton, Ohio. Filed Nov. 11, 1901. Serial No. 81,896. (No model.)



Claim.—1. As a new article of manufacture, the herein-described clamp comprising two interlocking members, the adjacent surfaces of which

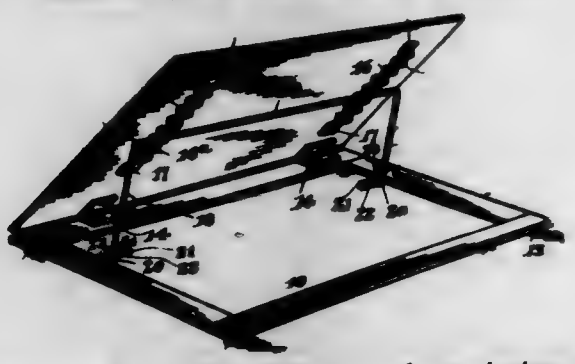
are provided with laterally-projecting lugs with adjacent recesses, the lower surfaces of said lugs when interlocked, providing a continuous rounded surface which provides a gradual curve to which curvature the rope or cable upon which said clamp is supported, conforms, the said clamp having a horizontal channel extending through it below the lugs and through which the said rope or cable passes, the said lugs forming the upper inclosure of said channel, and means for securing the clamp members together.

2. A suspension-clamp consisting of two interlocking members having a horizontal channel in the adjacent surfaces thereof through which a rope or cable passes, laterally-projecting lugs on the adjacent surfaces of said members, adjacent recesses into which said lugs project, the said lugs having their lower surfaces suitably rounded to provide a continuous and uniform curve, to which curvature the rope or cable conforms, and means for connecting said members above and below the rope or cable.

3. In a suspension-clamp for cables, the combination with a pulley-case, of a suspension-clamp consisting of two interlocking members to which said case is swiveled, the said interlocking members having a horizontal channel therein through which the cable passes, laterally-projecting lugs on the inner adjacent surfaces of said members above the channel through which the cable passes, the lower surfaces of said lugs forming a curved inclosure for the top of said channel, recesses adjacent to said lugs into which the lugs on the opposite members project, and means for connecting said members above and below the horizontal channel.

4. A new article of manufacture, comprising a suspension-clamp, having a channel therein through which a rope or cable passes, a suitably-rounded surface in said clamp which lies above the rope or cable and forms a bearing-surface between the clamp, and the rope or cable, the said bearing-surface being rounded to conform to the curvature of the rope or cable, and whereby any sharp edges or corners of the clamp are prevented from coming in contact with the rope or cable.

706,228. ADJUSTABLE SUPPORT. ANDREW FLEMING, Brooklyn, N. Y. Filed June 11, 1901. Serial No. 64,158. (No model.)



Claim.—1. The combination with a rack, of a stem having a spring at one end and an eye at the other, said spring being secured to the rack, and a cross-bar rotatably mounted intermediate its ends in the eye of the stem.

2. The combination with a rack, of a stem having a yielding and pivotal connection at one end with the rack and provided at its other end with an eye, a cross-arm having an ear that passes through the eye of the stem, and a keeper passing through the ear of the cross-arm to hold it in place.

3. The combination with a rack, of a stem having a yielding and pivotal connection at one end with the rack and provided at its other end with an eye, and a cross-arm comprising a single piece of metal bent to form a pair of loops and an intermediate offset ear that passes through the eye of the stem, the terminals of said metal piece passing through the offset ear thereof to hold the cross-arm in place.

706,229. FUEL-SAVER AND SMOKE-CONSUMER. CHARLES W. FRANCOIS, Brantford, Canada. Filed Nov. 27, 1901. Serial No. 83,892. (No model.)

Claim.—1. In a device of the class described, a bridge-wall provided with hot-air ports and pockets or recesses; in combination with superheating air-conducting pipes open at both ends and located in said bridge-wall, the upper one of said pipes provided with openings leading into said hot-air ports, in said bridge-wall, and said pockets or recesses being formed in said bridge-wall at the ends of said pipes, so that the air will be conducted from one pipe to the other, and one of said pipes extending to the outside of the boiler-wall, substantially as and for the purpose set forth.

2. In a device of the class described, a bridge-wall provided with hot-air ports and pockets or recesses, in combination with superheating and air-conducting pipes, open at both ends, and located in said bridge-wall, the upper one of said pipes provided with openings leading into said hot-air ports in said bridge-wall, and said pockets formed in said bridge-wall, at the ends of said pipes, so that the superheated air will pass from one pipe to the other, and one of said pipes extending to the outside of the boiler-wall, and abutment-plates at the upper side of each of said pockets or recesses, substantially as and for the purpose set forth.

3. In a device of the class described, a bridge-wall provided with hot-air ports and pockets or recesses, superheating air-conducting pipes open at both ends and located in said bridge-wall, the upper one of said pipes provided with openings leading into said hot-air ports, in said bridge-wall, and said pockets or recesses formed in said bridge-wall, at the end of said pipes so that air will be conducted from one pipe to the other, and one of said pipes extending to the outside of the boiler-wall, in combination with a steam-boiler, a combustion-chamber, a baffle-wall located therein, openings in said baffle-wall, and a draft-opening between said boiler and said baffle-wall, substantially as and for the purpose set forth.

4. In a device of the class described, a bridge-wall provided with hot-air ports and pockets or recesses, superheating air-conducting pipes open at both ends and located in said bridge-wall, the upper one of said pipes provided with openings leading into said hot-air ports, in said bridge-wall, and said pockets or recesses formed in said bridge-wall, at the end of said pipes so that air will be conducted from one pipe to the other, plates at the upper side of each of said pockets or recesses, and one of said pipes extending to the outside of the boiler-wall, in combination with a steam-boiler, a combustion-chamber, a baffle-wall located therein, openings in said baffle-wall, and a draft-opening between said boiler and said baffle-wall, substantially as and for the purpose set forth.

5. In a device of the class described, a bridge-wall provided with hot-air ports and pockets or recesses, superheating and air-conducting pipes, open at both ends, and located in said bridge-wall, the upper one of said pipes provided with openings leading into the hot-air ports in said bridge-wall, and said pockets or recesses formed in said bridge-wall at the end of said pipes so that the air will be conducted from one pipe to the other, and one of said pipes extending to the outside of the boiler-wall, in combination with a combustion-chamber, a baffle-wall located therein in which openings are formed, and a draft-opening between the boiler and said baffle-wall, and one or more series of superheating air-conducting pipes located in said combustion-chamber, openings in each series of said pipes, and one of each of said series of said pipes extending to the outside of the boiler-wall, substantially as and for the purpose set forth.

6. In a device of the class described, a bridge-wall provided with hot-air ports and pockets or recesses, superheating air-conducting pipes open at both ends and located in said bridge-wall, the upper one of said pipes provided with openings leading into the hot-air ports in said bridge-wall, and said pockets or recesses formed in said bridge-wall at the end of said pipes so that the air will be conducted from one pipe to the other, plates at the upper side of each of said pockets or recesses, and one of said pipes extending to the outside of the boiler-wall, in combination with a combustion-chamber, a baffle-wall located therein in which openings are formed, and a draft-opening between the boile and said baffle-wall, and one or more series of superheating air-conducting pipes located in said combustion-chamber, openings in each series of said pipes, and one of each of said series of said pipes extending to the outside of the boiler-wall, substantially as and for the purpose set forth.

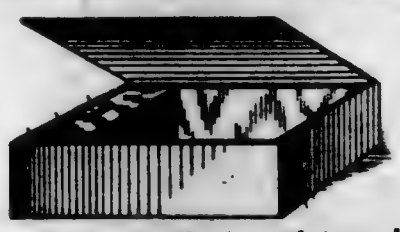
706,230. TRIANGLE. CHARLES W. FULLER, Medway, Mass. Filed July 19, 1901. Serial No. 68,961. (No model.)

Claim.—1. The combination, with a base-plate provided with a foot-plate at one end and a standard at the other end, of a triangle suspended from the standard, a spring-supported foot-lever hinged at one end to one end of the said foot-plate, and a hammer-head provided with a spring-shank which is inserted in the free end portion of the said foot-lever, substantially as set forth.

2. The combination, with a base-plate provided with a foot-plate at one end and a standard at the other end, of a triangle suspended from the standard, a spring-operated foot-lever pivoted at one end to the foot-plate, a spring-hammer projecting from the other end of the foot-lever and engaging with the triangle, and a damper of soft material mounted to

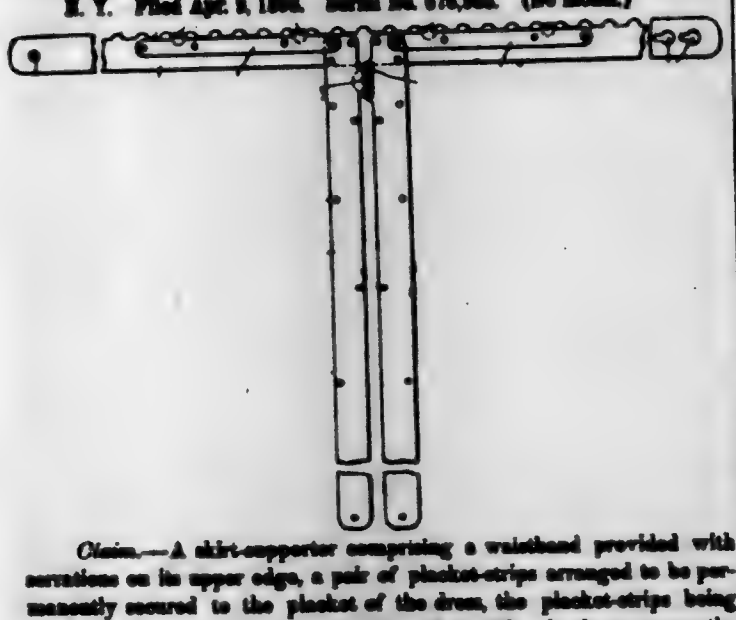
the base-plate under the front end portion of the said foot-lever, substantially as set forth.

706,281. BOX OR RECEPTACLE. DAVID GOLDMAN, Milwaukee, Wis. Filed Sept. 26, 1901. Serial No. 76,526. (No model.)



Claim.—As an improved article of manufacture, a box or receptacle having a main chamber provided with an open top, said chamber adapted for containing articles to be sold, a cover for the open top of the main chamber, and normally closing said open top, but adapted to be moved so as to open and close the same, and thereby permit articles to be freely placed therein and removed therefrom, a separate money-compartment fast to the box, and having its outer side removable to provide for access to the interior thereof, and the remaining sides closed, the upper closed side having a coin-slot therethrough for the introduction of money into the compartment.

706,282. SKIRT-SUPPORTER. LOUIS E. HAGUENELLE, New York, N. Y. Filed Apr. 9, 1900. Serial No. 672,262. (No model.)

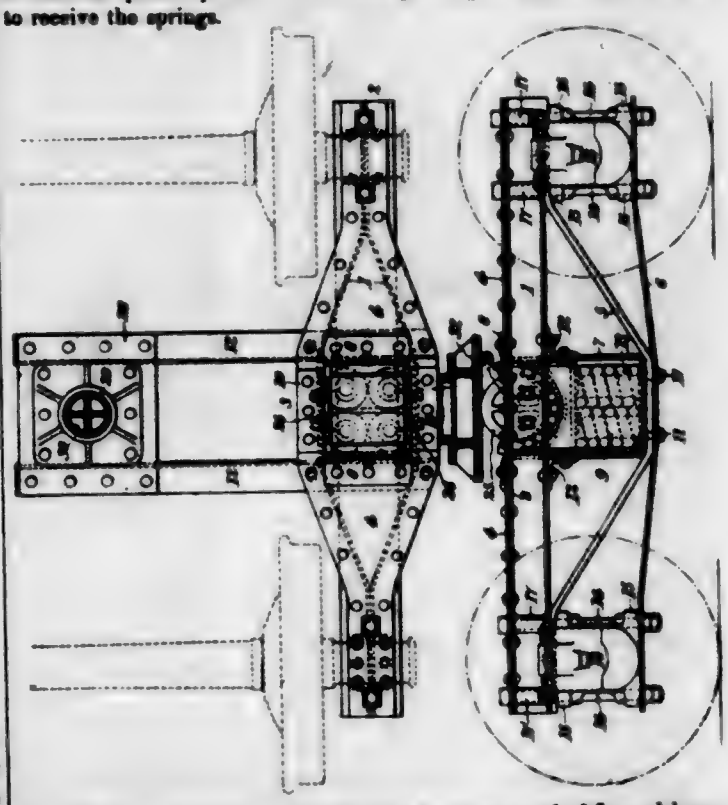


Claim.—A skirt-supporter comprising a waistband provided with serrations on its upper edge, a pair of placket-strips arranged to be permanently secured to the placket of the dress, the placket-strips being provided, the one with an eye and the other with a hook to engage the eye, the latter extending in the vertical plane of the waistband and a pair of arms pivotally secured to the placket-strips and provided with hooks for engaging the serrations in the band, the said arms serving, when engaged with the serrated edge of the band, to prevent the placket-strips from movement toward and away from each other to unhook and the said hook when in position preventing the strips from vertical movement by its engagement with the lower edge of the band, substantially as set forth.

706,283. TRUCK-FRAME FOR RAILWAY-CARS. JOHN M. HARRIS, Pittsburg, Pa. Filed Jan. 9, 1902. Serial No. 89,054. (No model.)

Claim.—1. A side frame, composed of a composite arch-bar, the members of which are brought together at opposite ends, and spaced apart between their ends, and adapted to receive the springs in substantially the center line of the truck.

2. A truck-frame, the upper arch-bar of each side of which is composed of flanged members, the ends of which are brought together, and the centers spaced apart in a substantially hexagonal figure, and adapted to receive the springs.



3. In a truck-frame, an upper arch-bar, composed of flanged beams arranged back to back, with their ends brought together over the journals, and spaced apart centrally, and provided with a spring-pocket in said centrally-spaced portion.

4. In a truck-frame, an upper arch-bar composed of flanged steel beams brought together at their ends over the journals, and spaced apart between their ends, top cover-plates rigidly uniting the said beams, and a longitudinally-arranged U-shaped stirrup rigidly fixed to the cover-plates, and depending therefrom, and another U-shaped stirrup arranged transversely of the first-named stirrup, and secured rigidly to the flanges of the beams, and depending therefrom within the first-named stirrup, the said stirrups constituting a spring-pocket.

5. A side frame, having an upper arch-bar composed of channel-beams arranged back to back at their ends, spaced apart between their ends, and connected rigidly by cover-plates applied to their ends, extending centrally toward each other and riveted to the flanges of the beams.

6. A truck-frame, having sides of substantially the character described, provided with centrally-arranged spring-pockets, springs arranged in said pockets, roller-bearings arranged in said pockets above the said springs and each bearing including a main roller, and adapted to support the load of the car by contact with the side bearings of the body-bolster.

7. A truck-frame, having roller-bearings in its side frames, and said frames connected by tie-bars provided with a socket, combined with a body-bolster supplied with side bearings resting directly upon said roller-bearings, and a pivot-pin cooperating with the socket aforesaid.

8. In a truck-frame, a side having an arch-bar provided with a spring-pocket, a spring arranged therein, a roller-bearing base also constituting a spring-cap, supporting-rollers and a retainer therefor arranged in said roller-bearing base, and a main roller-bearing arranged upon the supporting-rollers.

706,284. TRUCK-FRAME FOR RAILWAY-CARS. JOHN M. HARRIS, Pittsburg, Pa. Filed Jan. 9, 1902. Serial No. 89,055. (No model.)

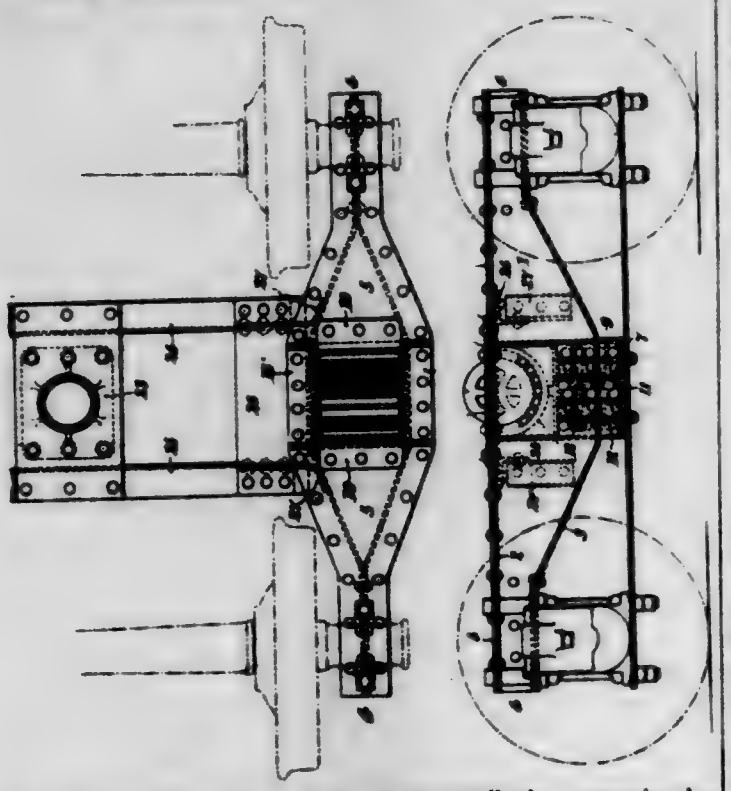
Claim.—1. A truck-frame, having a side composed of two complemental members brought together at their ends, and spaced apart centrally, and in which the upper and lower arch-bars are in one, substantially as described.

2. A truck-frame, having a side composed of complemental members brought together at their ends, and spaced apart centrally, and in which the upper and lower arch-bars are formed of solid pressed-steel flanged beams.

3. A truck-frame, having a side composed of complemental pressed-steel laterally-flanged beams, of greatest vertical width in their center, brought together at their ends, and spaced apart laterally between their ends, and united by cover-plates riveted to the upper flanges.

4. A truck-frame, having a side composed of a pair of solid pressed-steel combined upper and lower arch-bars, brought together at their ends, and spaced apart laterally at their center, a spring-pocket arranged in

said spaced-apart center, and tie-bars secured by plates to the inner members of the adjacent sides.

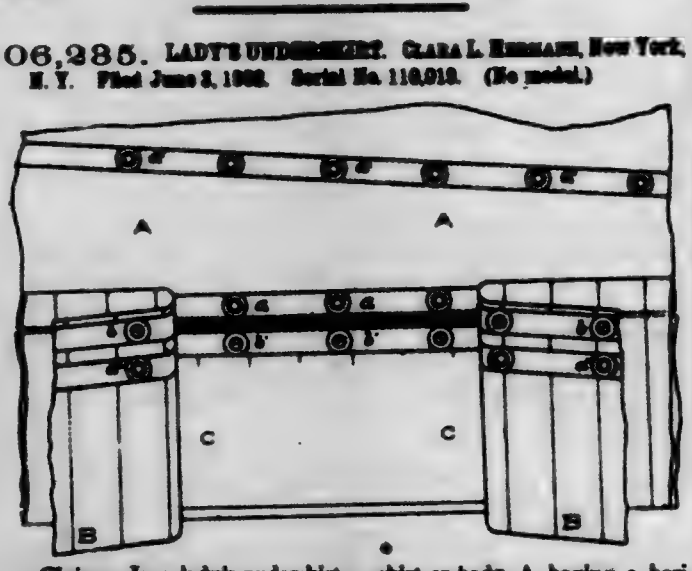


5. A truck-frame, having a side of substantially the construction described, provided with a central spring-pocket, a roller-bearing arranged in said pocket above the springs, and chafing-plates interposed between the roller-bearing and the spring-pocket.

6. A truck-frame, having a side of substantially the construction described, provided with a central spring-pocket, a roller-bearing arranged in said pocket above the springs, and chafing-plates interposed between the roller-bearing and the spring-pocket, said roller-bearing comprising a base, having a semicircular cavity, a roller-retainer arranged in said cavity and containing supporting-rollers, and a main roller arranged upon the supporting-rollers, the several parts of the bearing abutting against the chafing-plates, substantially as described.

7. A truck-frame, having a side composed of a pair of combined upper and lower arch-bars, brought together at their ends, and spaced apart centrally between said ends, and a spring-pocket within such spaced-apart portion.

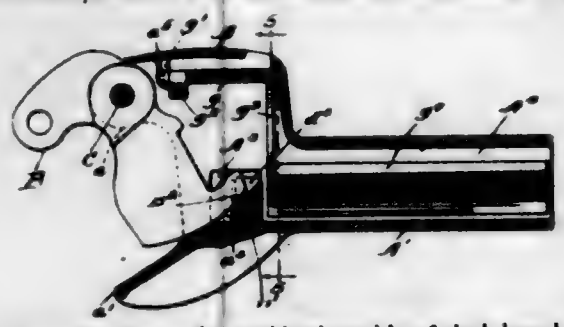
706,285. LADY'S UNDERSHIRT. CLARA L. HERMANN, New York, N. Y. Filed June 3, 1902. Serial No. 110,919. (No model.)



Claim.—In a lady's undershirt, a shirt or body, A, having a horizontal row of fastenings, *a a*, at the bottom, and a diagonal arrangement of fastenings, *a' a'*, just above the horizontal row, in combination with a flounce, B, wider in its rear section than in its front section, and also provided with a row of complemental fastenings, *b b*, whereby the double function of a trailing or a short shirt may be secured in a single garment, substantially as described.

706,286. AUTOMATIC CAR-COUPLING. GUSTAF A. HERMANSEN, Chicago, Ill., assignor to James Manton, Maywood, Ill. Filed June 7, 1902. Serial No. 110,962. (No model.)

Claim.—1. In an automatic car-coupler, the combination of a forked draw-head having a shouldered passage for a lock, and a groove or bearing in its pivot-arm for a knuckle-thrower, a gravity-lock having a shoulder fitting under the shoulder on the draw-head to prevent the lock from creeping, a lifting-piece having a sliding connection with the lock and provided with a shoulder or enlargement to hold the shoulder on the locking-pin under the shoulder on the draw-head when the coupler is locked, and a weighted or gravity-acting crank-shaped knuckle-thrower having an operating-arm engaging the tail of the knuckle, a weight fitting in the chamber of the draw-bar, and an arm connecting the weight with the pivot or shaft portion of the knuckle-thrower, substantially as specified.



2. In a car-coupler, the combination with a forked draw-head and pivoted knuckle, of a crank-shaped gravity knuckle-thrower, substantially as specified.

3. In a car-coupler, the combination with a forked draw-head and pivoted knuckle, of a knuckle-thrower having a weight fitting in the chamber of the draw-bar, a pivot or shaft portion and an operating-arm engaging the tail of the knuckle to throw the same open, substantially as specified.

4. The combination in a car-coupler, with a draw-head having a groove or bearing for a knuckle-thrower in its pivot-arm, of a knuckle, and a gravity knuckle-thrower having a shaft or pivot portion *g*, an operating-arm g^2, a curved arm g^3 and a weight-bar g^4 fitting in the chamber of the draw-bar, substantially as specified.

5. In a car-coupler, the combination with the forked draw-head, of a knuckle, a gravity-lock having a shoulder, a shoulder on the draw-head engaging the shoulder on the lock, and a sliding lifting-piece having a shoulder or enlargement, substantially as specified.

6. In a car-coupler, the combination with the forked draw-head, of a knuckle, a gravity-lock having a shoulder, a shoulder on the draw-head engaging the shoulder on the lock, and a sliding lifting-piece having a shoulder or enlargement, said lifting-piece and lock having a sliding head and slot connection with each other, substantially as specified.

7. In a car-coupler, the combination with a draw-head having a shoulder, of a knuckle, a lock D having a shoulder *d* engaging the shoulder on the draw-head and provided with a slot *d'*, having an opening d^2 at one side, and a sliding lifting-piece F, having a shoulder or enlargement *f* and an integral head f^2 and connecting web or neck f^3, substantially as specified.

8. In a car-coupler, the combination with a knuckle, of a forked draw-head having a shouldered passage-way for a lock, of a gravity-lock having a shoulder engaging the shoulder on the draw-head, a lifting-piece having a sliding connection with the lock, and a shoulder or enlargement to hold the shoulder on the lock under the shoulder on the draw-head, said lock being provided with an extension D' at its lower end having a projecting foot to serve as a lock-set, substantially as specified.

9. In a car-coupler, the combination with a knuckle, of a forked draw-head having a shouldered passage-way for a lock, of a gravity-lock having a shoulder engaging the shoulder on the draw-head, a lifting-piece having a sliding connection with the lock, a shoulder or enlargement to hold the shoulder on the lock under the shoulder on the draw-head, said lock being provided with an extension D' at its lower end having a projecting foot to serve as a lock-set, said projecting foot also engaging the tail of the knuckle to prevent the lock being separated from the draw-head substantially as specified.

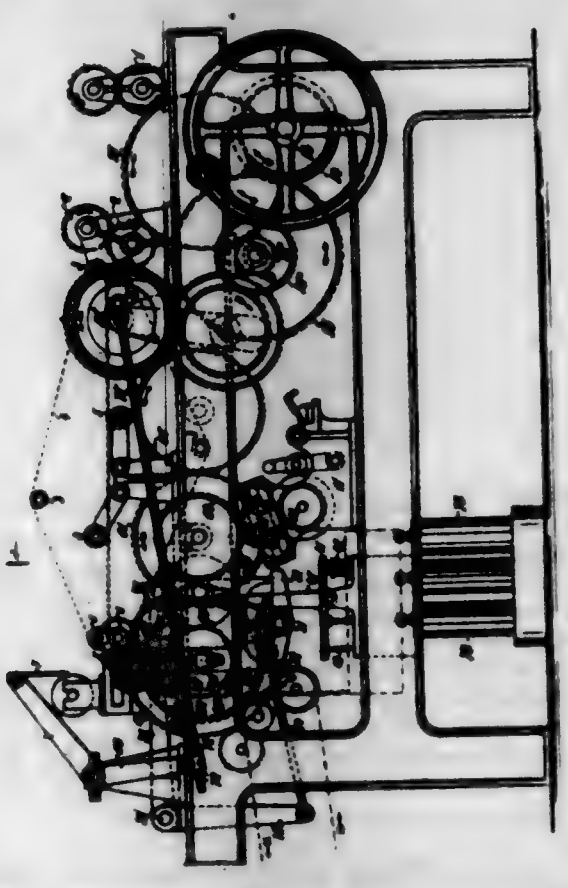
10. In a car-coupler, the combination with a forked draw-head, of a knuckle and a gravity-lock D, having an extension D' at its lower end provided with a projecting foot d^3 to serve as a lock-set and prevent removal of the lock from the draw-head by engagement with the tail of the knuckle, substantially as specified.

11. In a car-coupler, the combination with the forked draw-head, of a knuckle, a gravity-lock having a shoulder, a shoulder on the draw-head engaging the shoulder on the lock, a sliding lifting-piece having a shoulder or enlargement, and a crank-shaped gravity knuckle-thrower having a weight-bar fitting in the hollow chamber of the draw-bar, a curved arm extending behind the tail of the knuckle, a pivot or shaft fitting in a groove in the pivot-arm of the knuckle, and an operating-arm, substantially as specified.

12. In an automatic car-coupler, the combination with a pivoted knuckle, of a forked draw-head having a shouldered passage for the locking-pin, of a gravity-lock having a shoulder adapted to fit under the shoulder in the passage-way of the draw-head to prevent the lock from creep-

ing, and a lifting-piece having a sliding connection with the lock and provided with a shoulder or enlargement at its upper end to force the shoulder on the locking-pin under the shoulder on the passage-way of the draw-head when the coupler is locked, substantially as specified.

706,287. PRINTING APPARATUS FOR USE WITH MACHINES FOR MAKING PAPER BAGS. HERMANN HÖLSCHER, Langerich, Germany. Filed Mar. 19, 1900. Serial No. 9,167. (No model.)



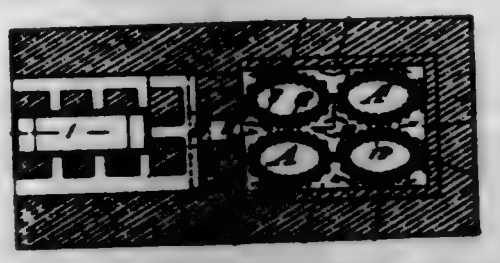
Claim.—1. In a bag-printing machine, the combination with the impression-cylinder mounted in swinging bearings, of cam-disks on the ends of the shaft of the cylinder bearing against circular disks mounted also in swinging bearings and double locking-lever, essentially as and for the purpose described.

2. In a bag-printing machine, the combination with the impression-cylinder mounted in swinging bearings, of cam-disks bearing against circular disks also mounted in swinging bearings, double locking-lever, and means for keeping the swinging bearings of the press-cylinder locked as long as the bags are regularly fed to the printing apparatus and for releasing them when the feed is interrupted.

3. In a bag-printing machine, the combination with the impression-cylinder mounted in swinging bearings, cam-disks on shaft of press-cylinder, circular disks, swinging bearings for same, and double locking-lever connected by lever system with the armature of an electromagnet, essentially as and for the purpose described.

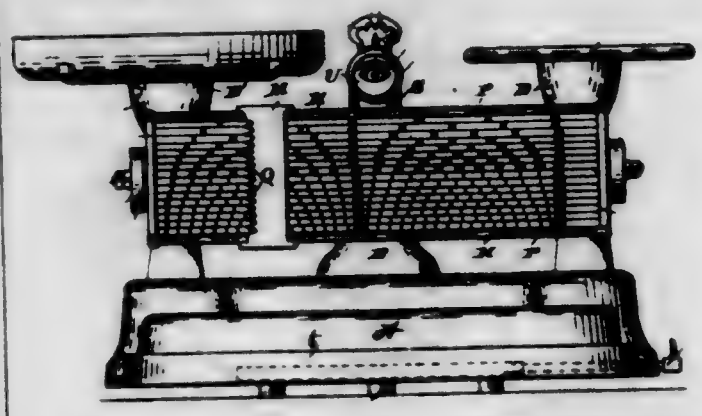
4. In a bag-printing machine, the combination with the impression-cylinder mounted in swinging bearings, cam-disks on shaft of press-cylinder, circular disks, swinging bearings for same, double locking-lever connected by link connection with a bell-crank lever, armature of electromagnet, and swinging support controlled by said armature, essentially as and for the purpose described.

706,288. GAS-REGULATOR. CHARLES W. ISSELL, New York, N. Y. Filed Aug. 21, 1901. Serial No. 73,722. (No model.)



Claim.—As a upright gas-retort having a single wall in the inner surface of which are upwardly-running channels and on the outer surface of which are upwardly-running ribs, substantially as and for the purpose herein described.

706,289. PRICE-SCALE. LEONARD T. JOHNSON, Brooklyn, N. Y. Filed Apr. 9, 1901. Serial No. 55,059. (No model.)



Claim.—1. In a weighing-scale, the combination with the beam, of a signal comprising a pivoted member, and an actuating-lever, both of which are carried by the beam, and a member mounted independently of the beam and adapted to be engaged by said lever, substantially as described.

2. In a weighing-scale, the combination with the beam, of a signal comprising a casing mounted upon the beam, a pivoted member in said casing, an actuating-lever pivoted in said casing for effecting the movement of the pivoted member, and a member mounted independently of the beam and adapted to be engaged by said lever, substantially as described.

3. In a weighing-scale, the combination with the beam, of a signal comprising a casing mounted upon the beam and having an aperture, a pivoted member mounted in said casing behind said aperture, an operating-lever pivoted in said casing and adapted to actuate said pivoted member and having an arm, and an arm fixed to the base of the scale and positioned in said casing in the path of said lever-arm, substantially as described.

4. In a weighing-scale, the combination with the beam, of a signal comprising an apertured casing mounted upon the beam and having an opening in its top wall, an arched plate above said open end having indicating projections, a pivoted member in said casing, an operating-lever pivoted in the casing and adapted to actuate the pivoted member, and an arm fixed to the base of the scale and disposed in said casing and adapted to effect the movement of said lever and having its upper end projecting through the open end of the casing and adapted to coact with the indicating projections of the arched plate, substantially as described.

5. In a scale, the combination with the beam, of a signal operated by the movement thereof, comprising a pivoted member mounted upon a crank-shaft, and an operating-lever actuated by the movement of the beam and adapted to engage the crank of said shaft, substantially as described.

6. In a scale, the combination with the beam, of a signal operated by the movement thereof, comprising a pivoted member mounted upon a crank-shaft, a pivoted lever having its free end disposed beneath the crank of said shaft, a support for the free end of the lever, said lever having an arm near its pivotal point, and a member adapted to actuate said lever by engagement with said arm, substantially as described.

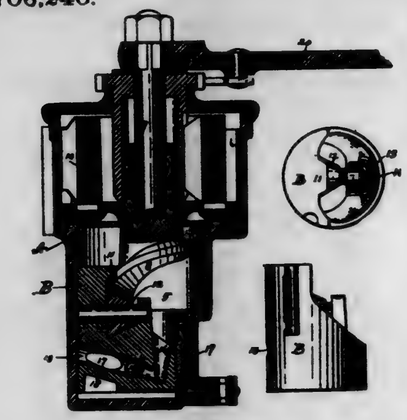
7. In a scale, the combination with the base formed with perforations and slots, of a detachable weight-shelf formed with horizontally-disposed lugs adapted to enter said slots, and with vertically-disposed shoulders adapted to bear against the outer surface of the base, and with slotted lugs, and securing members adapted to pass through said perforations and slotted lugs, substantially as described.

706,240. LIQUID DOOR-CHECK. HORACE E. JONES, Hartford, Conn., assignor to the Russell and Erwin Manufacturing Company, New Britain, Conn. Filed Feb. 28, 1902. Serial No. 96,071. (No model.)

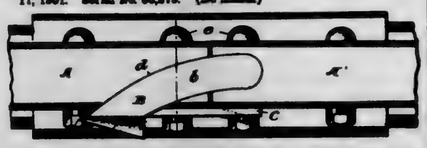
Claim.—1. In a liquid door-check, the combination of the piston having the passage 16 leading downwardly from its upper end, a transverse passage 18 leading from the periphery inwardly to the said passage 16, said passage 18 having a valve-seat therein and transverse openings leading down to the lower end of the piston, with a ball-valve confined within the said passage 18, substantially as described.

2. In a liquid door-check, a piston provided with an opening extending therethrough, part of said opening consisting of a transverse inclined passage having open communication with the lower end of said piston, said inclined passage being contracted in its lower portion to form a valve-seat, said contracted portion having open communication with the upper end of said piston, a ball-valve in said inclined passage and normally held by gravity in such relation to its seat as to permit the flow of liquid in one direction only, substantially as described.

706,240.



706,241. RAIL-JOINT. KENT KOSS, Lincoln, Nebr. Filed Dec. 17, 1901. Serial No. 86,379. (No model.)



Claim.—1. The combination of two rails arranged end to end and provided with a curved, open-topped groove opening out at one side of one rail and extending into the other rail, and a curved bar fitted into said groove, substantially as set forth.

2. The combination of two rails arranged end to end and provided with a curved, open-topped groove opening out at one side of one rail and extending into the other rail, and a curved bar fitted into said groove, said groove and bar having inclined surfaces on their sides, to prevent vertical movement of the bar in the groove, substantially as set forth.

3. The combination of two rails arranged end to end and provided with a curved, open-topped groove opening out at one side of one rail and extending into the other rail, a curved bar fitted into said groove, and means to secure the bar to the rails, substantially as set forth.

4. The combination of two rails arranged end to end and provided with a curved, open-topped groove opening out at one side of one rail and extending into the other rail, and a curved bar, fitted into said groove, said bar having surfaces at its outer end against which a tool may bear to force the bar out of the groove, substantially as set forth.

5. The combination of two rails arranged end to end and provided with a curved, open-topped groove opening out at one side of one rail and extending into the other rail, a curved bar fitted into said rail and a plate rigidly connected to the bar to lie parallel with said rails and be secured thereto, substantially as set forth.

6. The combination of two rails arranged end to end and provided with a curved, open-topped groove opening out at one side of one rail and extending into the other rail, a curved bar fitted into said groove, and a coating on said bar to prevent corrosion, substantially as set forth.

7. The combination of two rails arranged end to end and provided with a curved open-topped groove opening out at one side of one rail and extending into the other rail, a curved bar fitted into said groove, and a coating on said bar and on the surface of said groove to prevent corrosion, substantially as set forth.

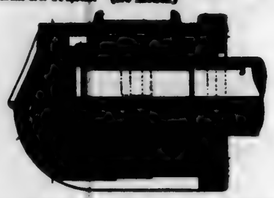
8. The combination of two rails arranged end to end and provided with a curved, open-topped groove opening out at the side of one rail and extending into the other rail, fish-plates and bolts to connect said rails, a curved bar fitted into said groove, a plate rigidly connected to said bar and lying against one of said fish-plates, said bar being provided with openings for the passage of said bolts, substantially as set forth.

9. The combination of two rails arranged end to end and provided with a curved, open-topped groove opening out at one side of one rail and extending into the other rail, and a curved bar fitted into said groove and cut from the open end thereof, said projecting portion being cut away to bring its upper surface below the upper surface of the rail, substantially as set forth.

706,242. MEASURING-RULE. ALLEN LAMBAW, Philadelphia, Pa. Filed Jan. 25, 1902. Serial No. 91,151. (No model.)

Claim.—A measuring-rule having units whereof each is divided by graduation-lines, which are equal in length to the fractional part of the unit which each line represents, and each of said divisions being subdivided by graduation-lines, which are equal in length to the fractional part of the division which each line represents, substantially as described.

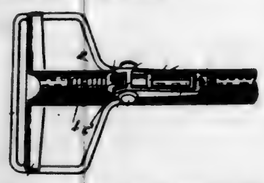
706,243. JOURNAL-BOX. SIMEON W. LEWIS, Portsmouth, Va., assignor of one-half to Caroline A. Hank, Norfolk, Va. Filed Apr. 24, 1902. Serial No. 104,023. (No model.)



Claim.—1. A journal-box, having a single rear wall, and its floor constructed with an inverted-V-shaped ridge extending from the front wall to within a short distance of the rear wall, the space between the said rear wall and the inner vertical surface or end of said ridge adapted to receive the lower end of the dust-guard, substantially as described.

2. A journal-box, having a single rear wall, and its floor constructed with an inverted-V ridge extending from the front wall to within a short distance of the said rear wall, there being a recess between the rear wall and inner vertical surface or end of the ridge, and a slotted top, said recess, slotted top and rear wall constituting a pocket for the dust-guard, substantially as described.

706,244. MOP-HEAD. JOHN C. LOCK TUCKER, Cal. Filed May 23, 1900. Serial No. 17,704. (No model.)



Claim.—1. In a mop-head, a handle provided with a clamp-head and with a ratchet, a pawl adjustably connected with the ratchet, a lever pivoted to the pawl at the end thereof engaging the ratchet and on the same side of the handle as the ratchet, and a clamp device pivoted to the lever.

2. In a mop-head, a handle provided with a clamp-head, a ratchet-bar on said handle, a pawl movable longitudinally along said ratchet-bar and having a body extending along the handle on the same side thereof as the ratchet-bar, means for maintaining the body of said pawl substantially parallel with the said ratchet-bar when in engagement, a lever pivoted to said pawl, and a clamping device pivoted to the lever.

3. In a mop-head, a handle provided with a clamp-head, a ratchet-bar on said handle having a retainer, a pawl movable longitudinally along said bar, its body portion being retained between said handle and retainer, a lever pivoted to said pawl, and a clamping device pivoted to the lever.

706,245. ROLL-HOLDING CAMERA. WILLIAM LOUDER, Fairfield, Iowa. Filed Apr. 16, 1902. Serial No. 103,210. (No model.)

Claim.—1. In a roll-holding camera, a removable plate having an opening in the central part of its body, and being adapted to be adjusted

in front of the sensitive film for an exposure of reduced size, or to be removed therefrom to permit a full-sized exposure.

2. In a roll-holding camera a series of plates, each having a different-sized opening in the central part of its body, each plate being adapted to be adjusted, one at a time, in front of a sensitive film of a size to correspond with the opening in its body, and to be removed therefrom to permit the use of a different-sized film.

3. In a roll-holding camera having two end compartments for the roll-holding spools, and a central compartment for the field of exposure, a removable plate having an opening in its body, and being adapted to be adjusted in front of the film and upon the partitions between the compartments so as to effectually shut out the light at the ends of the plate, and limit the size of exposure.

4. In a roll-holding camera, a removable plate having an opening in its body adapted to be adjusted in front of the film to regulate the area of the exposure, and flanges on its back to guide the passage of the film over said opening.

5. In a roll-holding camera having two end compartments for the roll-holding spools, and a central compartment for the field of exposure, a removable plate having an opening in its body, and being adapted to be adjusted in front of the film and into rabbets in the edges of the partitions and also in the sides of the body of the camera to shut out the light at the edges of the plate and limit the size of exposure.

6. In a roll-holding camera, a removable plate having an opening in its body, adapted to be adjusted in front of the film to regulate the area of the exposure and means in the body of the holder to the rear of the film for storing the plate when not in use.

7. In a roll-holding camera, a series of removable plates, each having an opening of a different size in its body adapted to be adjusted in front of the film to regulate the area of the exposure, and means in the body of the holder to the rear of the film for storing said plates one being adapted to fit upon another.

8. In a roll-holding camera a removable plate having an opening in its body adapted to be adjusted in front of the film to regulate the area of the exposure, and spring-clamps secured to the back of the holder to clamp the plate in position to the rear of the film when not in use.

9. In a roll-holding camera having plates, each having an opening in its body for regulating the area of exposure, a hook with a right-hole having an extension on its inner side, and means for storing said plates on said hook so as to surround said extension.

10. In a roll-holding camera, metallic spindles adapted to pass into the bore of the roll-holding spools, said spindles having angular corners longitudinally disposed thereon, and said corners being adapted to impinge against the wall of said bore and hold the spools fixed upon the spindles.

11. In a roll-holding camera, roll-holding spools having cylindrical bores, and metallic spindles adapted to pass into said bores, said spindles having angular ribs longitudinally disposed thereon and said ribs being adapted to become indented in the wall of the bore and hold the spool fixed thereon.

706,246. RELEASING-HOOK FOR HANDLING LOGS, &c. EDGAR F. HARE, Clinton, Ala. Filed Oct. 17, 1901. Serial No. 78,980. (No model.)

Claim.—The herein-described device for handling logs, &c., consisting of a cable, a trolley thereon, a hoisting-line running over said trolley, a releasing-hook on the lower end of said line consisting of a shank, a releasing-lever pivoted to the lower end of said shank, a releasing-latch for releasing said lever, a tripping-cord connecting said latch with the trolley and a binding-chain secured by one end to the shank and by the other end to the releasing-lever.

706,247. STOPPERING BOTTLES, JARS, OR OTHER VESSELS. FREDERICK W. HARGREVE, East Dulwich, England. Filed Oct. 10, 1901. Serial No. 78,361. (No model.)

Claim.—1. A bottle, jar or other vessel having a neck internally screw-threaded and formed with an upwardly-projecting tapering ledge, with a tapering space between the neck-wall and the ledge and an intervening tapering blank part between the lower part of the screw-thread and the ledge, substantially as described.

2. A bottle, jar or other vessel having a neck internally screw-threaded, and formed with an upwardly-projecting tapering ledge, with a tapering space between the neck-wall and the ledge and an intervening blank or straight part between the lower part of the screw-thread and the ledge, a screw-stopper fitting the internal screw-thread on the neck and provided with a longitudinal aperture therethrough containing a cork or other compressible washer which extends below the under surface of the stopper so as to take a seating on the ledge on the neck of the bottle or other vessel when the stopper is screwed down, substantially as described and for the purpose stated.

3. In combination with a bottle, jar or other vessel having a neck with an internal screw-thread and a ledge or seat with a space between the neck-wall and the ledge, and an intervening blank or straight part between the lower part of the screw-thread and the ledge, a screw-stopper fitting the internal screw-thread on the neck and provided with a longitudinal aperture therethrough containing a cork or other compressible washer which extends below the under surface of the stopper so as to take a seating on the ledge on the neck of the bottle or other vessel when the stopper is screwed down.

4. In combination with a bottle, jar or other vessel having a neck internally screw-threaded and formed with an upwardly-projecting, tapering ledge, with a tapering space between the neck-wall and the ledge and an intervening blank or straight part between the lower part of the screw-thread and the ledge, a screw-stopper fitting the internal screw-thread on the neck, and a compressible washer carried by the said screw-stopper and extending below the under surface of the stopper whereby to take a seating on the ledge on the neck of the bottle, or other vessel when the stopper is screwed down.

5. In combination with a bottle, jar or other vessel having a neck with an internal screw-thread and an upwardly-projecting tapering ledge, with a tapering space between the neck-wall and the ledge, and an intervening tapering blank part between the lower part of the screw-thread and the ledge, a screw-stopper fitting the internal screw-thread on the neck, and a tapering compressible washer carried by the screw-stopper and extending below the under surface of the stopper so as to take a seating on the ledge on the neck of the bottle or other vessel, when the stopper is screwed down and be wedged in position against the tapering wall of the said blank part, substantially as described.

706,248. DRAFT ATTACHMENT. NICHOLAS KIECHER, Oldham, S. D. Filed Apr. 15, 1902. Serial No. 103,080. (No model.)

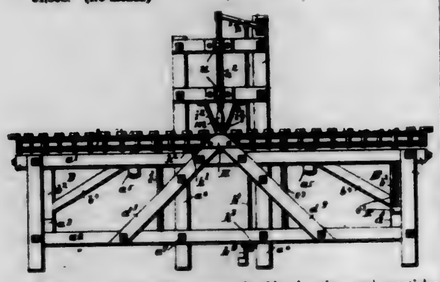
Claim.—1. A draft attachment comprising sections 1 and 2, hinged together at one end of the attachment, a rotary locking-pin mounted on

the section 1 and provided between its ends with a cut-away portion, arranged to engage the section 2, an exterior lever connected with one end of the locking-pin and adapted to operate the same, and a spring engaging the other end of the locking-pin, substantially as described.

2. A draft attachment, comprising the section 1 provided with a recess at one end and having an opening intersecting the recess, the section 2 hinged to the other end of the section 1 and provided with a catch, arranged in the recess when the attachment is closed, a rotary locking-pin mounted in the opening of the section 1 and provided with means for engaging the catch and having a recess at one end, a lever, connected with the other end of the locking-pin and a spring mounted on the section 1 and engaging the recess of the locking-pin and holding the latter against movement and retaining the same in the opening, substantially as described.

3. A draft attachment, comprising the section 1 having a shank provided with lugs, spaced apart and having recesses, a spring, arranged between the lugs and engaging the recesses thereof, the section 2 hinged to the section 1, a locking-pin mounted on the section 1 and arranged to engage the section 2 to hold the same closed and engaged by the said spring and means for operating the locking-pin, substantially as described.

706,249. **MECHANISM FOR COVERING BICYCLE-GRIPS, &c.** JAMES A. MILLER, New Haven, Conn. Filed Nov. 5, 1901. Serial No. 81,562. (No model.)



Claim.—1. In a machine for covering bicycle-grips or other articles of manufacture, the employment of an elastic former for compressing and shaping the covering upon the surface of the article, in combination with mechanism for forcing the elastic former into conformation with the article to be covered, substantially in the manner and for the purpose specified.

2. In a machine for covering bicycle-grips or other articles of manufacture, the combination of a conveyer, a series of former-supporters carried by the conveyer, elastic formers carried by the supporters, a plunger for forcing the formers upon the surface to be covered, and an anvil for sustaining the thrust of the plunger substantially as and for the purpose specified.

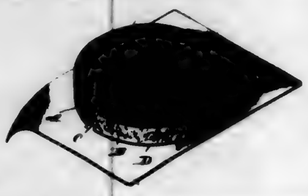
3. In a machine for covering bicycle-grips or other articles of manufacture the combination of an endless conveyer, a series of holders carried by the conveyer, elastic formers carried by the holders, plunger mechanism for forcing the elastic formers into conformation with the article to be covered, and an anvil for resisting the thrust of the plunger mechanism provided with a clearance-way for the passage through it of the covered articles while held projecting through the dies and carried along by the conveyer, substantially in the manner and for the purpose specified.

4. In a machine for covering bicycle-grips or other articles of manufacture, the combination of a frame, upright shafts and carrying-wheels supported upon the frame, an endless conveyer supported upon the wheels, a series of sockets carried by the conveyer, elastic formers carried by the sockets, a plunger for forcing the article to be covered within the formers, an anvil provided with a clearance-way for the passage through it of the covered articles while held projecting through the formers and carried along by the conveyer, and an opening for the exit of the finished work from the former by the stroke of the plunger, and mechanism for propelling the conveyer by a step-by-step movement and locating the formers centrally coincident with the axis of the plunger, substantially in the manner and for the purpose specified.

5. In mechanism for propelling an endless conveyer by step-by-step movement, the combination of a series of operating-lugs spaced along the conveyer, a lever, a pawl carried by the lever for engaging said lugs, a spring for actuating the pawl into engagement with the lugs, a handle pivotally attached to the lever engageable with the pawl to release the same from the lugs, and stops limiting the pivotal play of the handle on the lever, substantially in the manner and for the purpose specified.

6. In a machine for covering bicycle-grips or other articles of manufacture, the employment of centrally-divisible clamps in combination with a sectional elastic former carried by the clamps, and mechanism for spreading and contracting the several sections of the clamp, substantially as and for the purpose specified.

706,250. **ADHESIVE SHIELD.** WALTER J. MÜLLER, Aurora, Ill., assignor to Bauer & Black, Chicago, Ill., a Corporation of Illinois. Filed June 8, 1901. Serial No. 63,727. (Specimens.)



Claim.—1. A shield of the character described consisting of a hollow body composed of independent members having a loose connection permitting the members to spread apart.

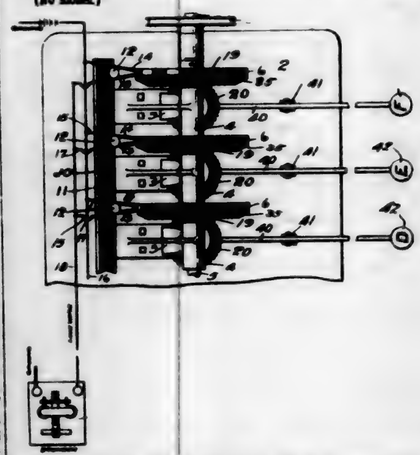
2. A shield of the character described consisting of a hollow body composed of independent members having a loose connection on one face thereof permitting the members to spread apart.

3. An adhesive shield of the character described consisting of two members, and a piece of fabric secured to said members on one face thereof and having that portion between the members puckered to provide a loose connection therefor, substantially as described.

4. A shield of the character described consisting of two members and provided on one face with a coating of adhesive material, and a piece of fabric affixed to the other face and folded between its connection with the members.

5. A hollow shield divided transversely into two separate members and provided on one face with a coating of adhesive material and a fabric covering for the other face having a folded full portion constituting a flexible connection between the members.

706,251. **MECHANICAL TELEGRAPH-TRANSMITTER.** JOSEPH W. MCDONALD, Larimore, N. D. Filed Jan. 27, 1902. Serial No. 91,350 (No model.)



Claim.—1. The combination, with a frame, of a series of disks loosely mounted therein and normally stationary, a series of contact-blocks of different widths arranged in the periphery of each disk and representing a single letter or character of the telegraph code, contact-brushes arranged in pairs and adapted to bear upon the peripheries of said disks, the brushes of each pair being insulated from each other and one being connected to the line-wire and the other to the battery, a series of levers, keys therefor, a driving mechanism, and means in connection therewith for causing a complete revolution of each disk when its lever is operated by the movement of the corresponding key.

2. The combination, with a frame, of a shaft horizontally arranged therein, a series of disks loosely mounted at intervals on said shaft an

provided in their peripheries with a series of contact-blocks that are insulated from each other, the blocks of each disk representing a single letter or character of the telegraphic code, contact-brushes arranged in pairs and adapted to bear upon the peripheries of said disks and on said blocks, each brush being insulated from the other brush of the same pair and from the other pair, said one brush of each pair being connected to the line-wire and the other to a battery, a series of levers, keys therefor, a driving mechanism, and suitable connections provided between said driving mechanism and each of said disks and adapted to be actuated by the movement of said levers when the corresponding key is operated.

3. The combination, with a shaft, of a series of loosely-mounted disks arranged at intervals thereon and provided at intervals in their peripheries with a series of contact or circuit-closing blocks of different widths insulated from each other and representing the letters or characters of a telegraphic code, brushes arranged in pairs and insulated from each other and connected with the battery and line wires respectively, the free ends of said brushes being adapted to bear upon the peripheries of said disks and alternately make or break the circuit as the disks are revolved, a keyboard and a series of levers therefor, and means controlled by the movement of said levers for causing a complete revolution of each disk when the key corresponding thereto is operated.

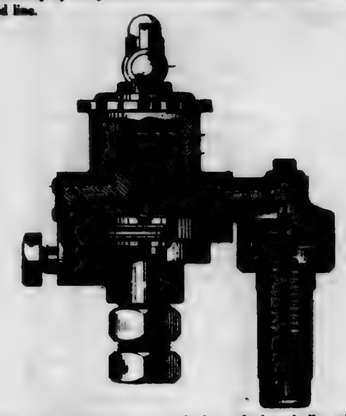
4. The combination, with a loosely-mounted disk of non-conducting material provided in its periphery with a series of circuit-closing or contact blocks of different widths arranged at intervals and representing the letters or characters of a telegraphic code, contact-brushes adapted to bear upon the periphery of said disk and connected respectively with the battery and line wires whereby the circuit will be closed when the brushes pass over a contact-block, a lever and key, and a gear mechanism controlled by the movement of said lever for causing a complete revolution of said disk when said key is operated.

5. The combination, with a loosely-mounted disk of non-conducting material provided in its periphery with a series of circuit-closing or contact blocks arranged at intervals and of different widths to represent the dots and dashes of a letter or character of a telegraphic code, brushes adapted to bear upon the periphery of said disk and connected respectively with the line and battery wires, whereby the circuit will be alternately closed and broken during the revolution of said disk, a gear provided on one face of said disk, an upright shaft provided with a gear engaging the gear on said disk, a loosely-mounted gear provided on said shaft, a driving-gear engaging said loosely-mounted gear, a clutch mechanism provided in connection with said loosely-mounted gear, and a lever and key for operating said clutch device to cause a complete revolution of said disk and the transmission of the letter or character represented thereby when the key is struck.

6. The combination, with a series of loosely-mounted disks of non-conducting material provided in their peripheries with a series of circuit-closing or contacting blocks arranged at intervals and of different widths to represent the dots and dashes of a letter or character of a telegraphic code, brushes arranged in pairs and adapted to bear upon the peripheries of said disks those of the same pairs being connected respectively with the line and battery wires, whereby the circuit will be alternately closed and broken during the revolution of said disks, gears provided on the faces of said disks, upright shafts having gears engaging said disk-gears, loosely-mounted gears on said shafts, driving-gears normally engaging said loosely-mounted gears, clutch mechanisms provided in connection with said loosely-mounted gears, springs for normally holding the movable members of said clutch mechanisms out of engagement with the fixed members thereof, key-levers provided with a series of keys and adapted to actuate said movable clutch members when the keys are struck to lock said loosely-mounted gears, and means for permitting the automatic disengagement of said clutch mechanisms when said disks have completed a single revolution.

706,252. **AIR-BRAKE.** FRANK A. MCELVEY, Knoxville, Pa. Filed June 17, 1901. Serial No. 64,881. (No model.)

Claim.—1. In an air-brake system employing a single train-line wherein the engineer's valve is connected with an equalizing discharge-valve, the combination with the engineer's valve, the train-line, and auxiliary reservoir, of a supplemental feed-port in the engineer's valve to communicate with the train-line, a supplemental air-passage from the train-line to the auxiliary reservoir, and an air-pressure-actuated check-valve in said passage which is adapted to open automatically by the pressure in the train-line when recharging said reservoir during brake application and close automatically by the pressure in the reservoir when a reduction is made in said line.



2. In an air-brake system employing a single train-line wherein the engineer's valve is connected with an equalizing discharge-valve and a train-line governor is arranged between said line and engineer's valve, the combination with the engineer's valve, train-line, and auxiliary reservoir, of a supplemental feed-port in the engineer's valve to communicate with the train-line, a supplemental air-passage from the train-line to the auxiliary reservoir, and an air-pressure-actuated check-valve in said passage which is adapted to open automatically by the pressure in the train-line when recharging said reservoir during brake application and close automatically by the pressure in the reservoir when a reduction is made in said line.

3. In an air-brake system employing a single train-line wherein the engineer's valve is connected with an equalizing discharge-valve and the auxiliary reservoir and train-line has means therebetween to permit recharging of said reservoir during brake application and prevent a return of air in said line when a reduction is made therein, of a supplemental feed-port in said engineer's valve.

4. In an air-brake system employing a single train-line wherein the engineer's valve is connected with an equalizing discharge-valve and a train-line governor is arranged between said line and engineer's valve and the auxiliary reservoir and train-line has means therebetween to permit recharging of said reservoir during brake application and prevent a return of air in said line when a reduction is made therein, of a supplemental feed-port in said engineer's valve.

5. In an engineer's air-brake valve provided with an equalizing discharge-valve and having a train-line governor to regulate the supply of air to the train-line, the combination therewith of a supplemental feed-port extending from the valve-seat to the passage leading from the governor to the main feed-passage.

6. In an engineer's air-brake valve provided with an equalizing discharge-valve and having a train-line governor to regulate the supply of air to the train-line, of a supplemental feed-port in said engineer's valve.

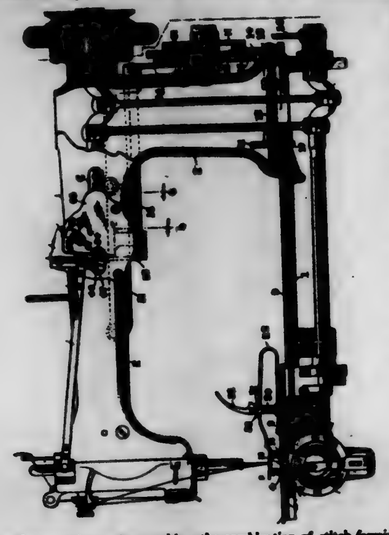
706,253. **EYELET-SEWING MACHINE.** DONALD NOBLE, Finsbury, London, England, assignor to Wheeler & Wilson Manufacturing Company, Bridgeport, Conn., a Corporation of Connecticut. Filed Apr. 4, 1900. Serial No. 11,495. (No model.)

Claim.—1. In an eyelet-sewing machine, the combination of stitch-forming mechanism including a reciprocating needle-bar, and means for feeding the material in a circular path, with mechanism for effecting a horizontal vibration of the needle-bar, and instrumentalities whereby said needle-bar may be brought to a standstill (as regards horizontal vibration) in a predetermined position intermediate of the limits of said horizontal vibration and its reciprocation continued, whereby a circular line of plain stitches will be made upon and intersecting the overseam-stitches previously made, as set forth.

2. In an eyelet-sewing machine, the combination of stitch-forming mechanism including a reciprocating needle-bar, mechanism for effecting a horizontal vibration of the needle-bar throughout a predetermined cycle of movement whereby overseam-stitches are made, instrumentalities for effecting a discontinuance of the horizontal vibration of said needle-bar whereby plain stitches are made upon and intersecting said overseam-stitches, and means for feeding the material, whereby each separate overseam-stitch will be anchored in place by a separate plain stitch, substantially as set forth.

3. In an eyelet-sewing machine, the combination of stitch-forming mechanism including a reciprocating needle, a cloth-clamp and means to carry around the material in a circular path, means to control the number of stitches to be made, means for horizontally vibrating the needle to permit the placing of a series of radial stitches, means for arresting such vibration at a predetermined point between the ends of the radial stitches and while the reciprocation of the needle continues and placing a circle

of plain stitches over and amid the lengths of thread of the radial stitches, and connections between the stitch-controlling means and the mechanism for arresting the horizontal vibration, by which connections the said horizontal vibration may be automatically resumed, substantially as described.



4. In an eyelet-sewing machine, the combination of stitch-forming mechanism including a needle-bar, means for feeding the material, a lever pivoted to the arm of the machine, means for oscillating said lever, a segment-lever pivoted on said oscillatory lever, operative connections between said segment-lever and the needle-bar, and means for locking said oscillatory lever and segment-lever together, substantially as set forth.

5. In an eyelet-sewing machine, the combination of stitch-forming mechanism including a needle-bar, means for feeding the material, a lever pivoted to the arm of the machine, means for oscillating said lever, a segment-lever pivoted on said oscillatory lever, operative connections between said segment-lever and the needle-bar, means for locking said oscillatory lever and segment-lever together, instrumentalities whereby said segment-lever may be disconnected from said oscillatory lever, substantially as set forth.

6. In an eyelet-sewing machine, the combination of stitch-forming mechanism including a needle-bar, means for feeding the material, an oscillatory lever pivoted to the arm of the machine, means for actuating said lever, a segment-lever pivoted on said oscillatory lever, operative connections between said segment-lever and the needle-bar, means for locking said oscillatory lever and segment-lever together, instrumentalities whereby said segment-lever may be disconnected from said oscillatory lever and shifted to a predetermined stationary position, for the purpose set forth.

7. In an eyelet-sewing machine, the combination of stitch-forming mechanism including a needle-bar, means for feeding the material, an oscillatory lever pivoted to the arm of the machine, means for actuating said lever, the segment-lever pivoted on said oscillatory lever, operative connections between said segment-lever and the needle-bar, means for locking said oscillatory lever and segment-lever together, and instrumentalities whereby said segment-lever may be disconnected from said oscillatory lever and shifted to a predetermined stationary position intermediate of the two extreme limits of the oscillatory movement of said lever, for the purpose set forth.

8. In an eyelet-sewing machine, the combination of stitch-forming mechanism including a needle-bar, means for feeding the material, an oscillatory lever pivoted to the arm of the machine, means for actuating said lever, a segment-lever pivoted on said oscillatory lever, operative connections between said segment-lever and the needle-bar, means for locking said oscillatory lever and segment-lever together, instrumentalities whereby said segment-lever may be disconnected from said oscillatory lever, and a suitably-supported cam-plate against which said segment-lever is forced when disconnected from said oscillatory lever, for the purpose specified.

9. In an eyelet-sewing machine, the combination of stitch-forming mechanism including a needle-bar, means for feeding the material, an oscillatory lever pivoted to the arm of the machine, means for actuating said lever, a segment-lever pivoted on said oscillatory lever, operative connections between said segment-lever and the needle-bar, means for locking said oscillatory lever and segment-lever together, instrumentalities whereby said segment-lever may be disconnected from said oscillatory lever, a stationary stop-block against which said segment-lever may abut when disconnected from said oscillatory lever previous to assuming the desired position for placing the line of plain stitches, and an adjustable cam-plate, suitably supported, against which said lever is subsequently forced into complete position for placing the line of plain stitches.

10. In an eyelet-sewing machine, the combination of stitch-forming mechanism including a needle-bar, means for feeding the material, an oscillatory lever pivoted to the arm of the machine, means, as a cam-disk, for actuating said lever, a segment-lever pivoted concentrically with the pivotal center of said oscillatory lever, operative connections between said segment-lever and the needle-bar, a spring whereby said segment-lever is held against said oscillatory lever, means for locking said levers together against independent oscillatory movement, a plunger housed within the hollow pivot of said oscillatory lever and in operative contact with said segment-lever, means including a cam for governing the number of stitches to be made, and operative connections between said plunger and said cam, substantially as set forth.

11. In an eyelet-sewing machine, the combination of stitch-forming mechanism including a needle-bar, means for feeding the material, an oscillatory lever pivoted to the arm of the machine, means for actuating said lever, a segment-lever pivoted concentrically with the pivotal center of said oscillatory lever, means for locking said levers together, operative connections between said segment-lever and the needle-bar, a plunger housed within the hollow pivot of said oscillatory lever and in operative contact with said segment-lever, means for governing the number of stitches to be made, a cam carried by said stitch-governing mechanism, a rock-shaft, a lever on one end of said rock-shaft which bears against said plunger, and a lever on the opposite end of said rock-shaft adapted to be engaged by the said cam, for the purpose specified.

12. A machine for stitching eyelet-holes, comprising essentially a rotating cloth-carrier, stitch-forming mechanism including a reciprocating needle-bar and needle, means to vibrate said needle-bar to form a series of radial stitches around the hole, means to arrest automatically the vibratory movement of the needle-bar between the hole and the outer extremity of the radial stitches while the reciprocation of said needle-bar continues at the point where thus arrested and while the feeding motion progresses uninterruptedly, thereby to form a circle of plain stitches around the border of the hole and amid the radial stitches, the said plain stitches embracing the radial stitches and tying them down, and means to stop the machine at any point during the formation of either the radial stitches or the plain stitches, substantially as described.

13. The combination of feed mechanism having a rotary motion, stitch-forming mechanism including a reciprocating needle-bar and needle, means to vibrate said needle-bar to form a series of radial zigzag stitches, and automatic means to arrest the vibratory movement of the needle-bar at some point between the limits of its vibration and while its reciprocating motion continues, thereby to form a circle of plain lock-stitches which severally embrace the constituent threads of each over-seam-stitch.

14. A machine for stitching eyelet-holes, comprising essentially a feed mechanism having a rotary motion, stitch-forming mechanism including a reciprocating needle-bar and needle, means to vibrate said needle-bar to form a series of radial stitches around the hole, and means to arrest automatically the vibratory movement of the needle-bar between the hole and the outer extremity of the radial stitches and continue the reciprocation of said needle-bar at the point where thus arrested and while the feed motion progresses uninterruptedly, thereby to form a circle of plain stitches around the border of the hole and amid the radial stitches, the said plain stitches embracing the radial stitches and tying them down.

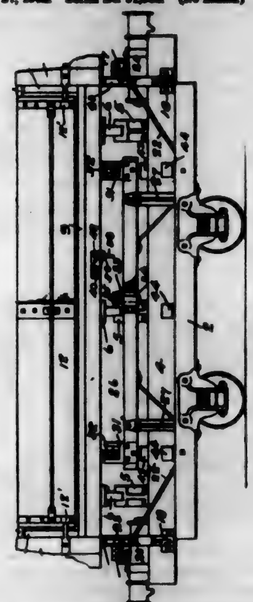
15. An eyelet-sewing machine, comprising a feed mechanism, means for overseaming the edges of the perforation with radial stitches, automatic means for arresting the radial stitching, and automatic means for inserting a circular line of plain stitches around the perforation and amid the radial stitches and thereby intersecting and stitching down the said radial stitches, substantially as described.

16. In a sewing-machine, the combination with stitch-forming mechanism comprising a needle-bar, of a work-support, means to produce a vibratory movement of the needle relatively to the work-support, and other independent automatic means to suspend such movement at a predetermined time to permit tying-stitches to be sewed.

17. In a sewing-machine, the combination with stitch-forming mechanism comprising a needle-bar frame, of a work-support, a main rock-lever, a pitman connecting said lever and the needle-bar frame, a supplementary rock-lever, means to actuate said last-named lever, and means to connect and disconnect said levers, whereby the movement of the first-named lever may be suspended.

18. In a sewing-machine, the combination with stitch-forming mechanism, of a work-support, a rock-shaft, a lever rigidly secured to said shaft and engaging a cam, a main rock-lever loosely mounted on said shaft, a pitman connecting said last-named lever to the needle-bar, a latch connection between said levers, and means to release the latch at a predetermined time to suspend the vibratory movement of the needle.

706,254. DUMPING-CAR. FRANCIS PUDLER, Minneapolis, Minn. Filed Jan. 27, 1902. Serial No. 91,202. (No model.)



Claim.—1. In a dumping-car, doors slidably supported upon swinging posts or standards.

2. In a dumping-car, swinging side doors, and reciprocating standards whereon said doors are removably and slidably supported.

3. In a dumping-car, standards pivoted near the center line of the car, and normally inclined toward the sides of the same, means for limiting the outward swinging movement of said standards and doors slidably supported at or near the upper ends of said standards.

4. In a car adapted to dump on both sides, doors closing only the sides of the car and slidably supported upon posts or standards, the connections of said doors with their supports permitting the doors to automatically adjust themselves to the tilted positions of the car-body.

5. In a dumping-car, swinging standards pivoted near the center line of the car, doors movably mounted upon said standards, each door being adapted to remain stationary when the car-body is tilted toward its side and to be raised above said standards when the car is tilted toward the opposite side, and suitable stops for limiting the inward movement of each door when so raised.

6. In a dumping-car, pivoted standards provided on each side of the center line, doors movably supported upon said standards, each door being adapted to remain stationary when the car is tilted toward its side and to be raised above said standards when the car is tilted toward the opposite side.

7. In a dumping-car, a door having pivots that are slidably supported upon posts or standards.

8. In a dumping-car, swinging standards pivoted near the center line of the car and provided near their upper ends with suitable sockets, and doors provided with pins that are adapted to enter said sockets and slide freely therein.

9. In a dumping-car, standards provided upon each side of the center line, timbers between which and the car-body said standards reciprocate, stops provided on said timbers for limiting the outward swinging movement of said standards, and doors pivotally supported upon the upper ends of said standards, and movable lengthwise thereof.

10. In a dumping-car, standards provided upon each side of the center line, doors slidably mounted on the upper ends of said standards and adapted to be raised one at a time above the same by the tilting of the car, and means provided on the ends of the car-body for limiting the inward movement of the door when so raised.

11. In a car adapted to dump on both sides, swinging standards or posts, doors slidably mounted at or near the upper ends of said standards, swinging bolsters provided beneath the car-body on each side thereof, and lever mechanisms for operating said bolsters.

12. In a car adapted to dump on both sides, swinging bolsters provided beneath the car-body, a lever mechanism connected with each bolster and operable on the opposite side of the car therefrom and means for locking said lever mechanism against premature movement.

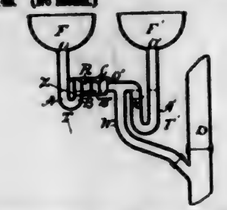
13. In a car adapted to dump on both sides, swinging bolsters provided beneath the car-body, levers pivoted on the car-body and adapted to oscillate lengthwise thereof, each lever being operable on the opposite side of the car from the bolster with which it is connected, and rods connecting said levers and bolsters.

14. In a car adapted to dump on both sides, inwardly-swinging bolsters provided under each side of the car and having idle rolls or wheels to engage the bottom of the same, a lever mechanism connected with each bolster and operable on that side of the car opposite from the bolster to which it is attached, and means for locking said lever mechanisms against premature movement.

15. In a car adapted to dump on both sides, standards pivoted near the center line of the car, castings provided at or near the upper ends of said standards and having pins slidably mounted to reciprocate on said standards, and doors having bearings in said castings.

16. In a dumping-car, doors supported independently of the car-body, each door being adapted to remain stationary when the car is tilted toward its side and to be raised above its supports when the car is tilted toward the opposite side.

706,255. APPARATUS FOR PROTECTING SEALS OF SEWER-GAS TRAPS. JOHN P. PUTNAM, Boston, Mass. Filed Apr. 8, 1902. Serial No. 102,149. (No model.)



Claim.—1. The combination of the plumbing-fixtures F F', traps T T' serving the fixtures, chamber R between the traps and the waste-pipe W, the trap T consisting of a shallow U-shaped return-bend, and the trap T' consisting of a deep U-shaped return-bend, and the chamber R consisting of a shallow reservoir between the two traps, the upcast limb of trap T connecting with the chamber at its bottom, and the trap T' connecting with the chamber at one of its sides at a point somewhat above its bottom, and the waste-pipe W, which serves both fixtures and their traps, connecting with them at a point between the chamber and the deep-seal trap, substantially as and for the purposes specified.

2. The combination of the plumbing-fixtures F F', traps T and T' serving the same, and waste-pipe W, the trap T having a shallow seal being provided with means for refilling it after siphonage, and the trap T' having a deep seal but without any such means of refilling, the two traps connecting with the same waste-pipe W, substantially as and for the purposes specified.

3. The combination with a U-shaped sewer-gas trap T, of a reservoir-chamber R and a waste-pipe opening O', the upcast limb B of the trap entering the chamber at its bottom, and the waste-pipe opening being on one side of the chamber a short distance above its bottom, the chamber being provided with a number of partition-walls a, b, extending from top to bottom of and dividing the chamber into a number of parts and forming a continuous waterway through the chamber, the entrance of the upcast limb of the trap being at one end of the waterway, and the waste-pipe opening O'' being at the other end, substantially as and for the purposes specified.

4. The combination of the trap T, chamber R, waste-outlet opening O', the chamber being provided with a movable cap C, the cap being bent upward at its outer edge, substantially as and for the purposes specified.

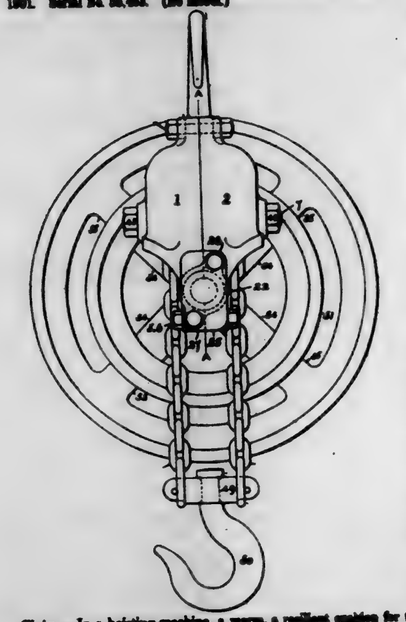
5. The combination of the trap T, reservoir-chamber R, waste-outlet opening O', the chamber consisting of a main body and a removable cap C, the cap having partitions a, b, rigidly secured thereto, the partitions descending to the bottom of the chamber, and dividing the cham-

ber into a continuous winding waterway, with means for making a water-tight connection between the body of the chamber and the cap, substantially as and for the purpose specified.

6. The combination of the trap T, reservoir-chamber R, waste-outlet opening O", the chamber consisting of a main body having a flat bottom B", provided with grooves K K and a removable cap C, the cap being provided with partitions *a b* secured thereto, and descending slightly below the bottom B" of the chamber, into said grooves K, K.

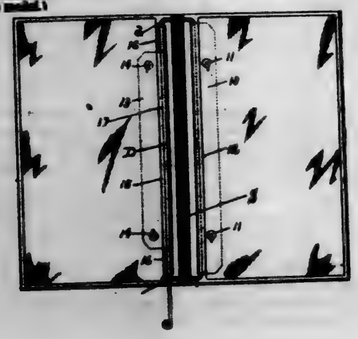
7. The combination of the trap T, reservoir-chamber R, waste-outlet opening O", standard S, circular partition *c' c'* concentric with the standard S, partition *b* extending from the standard to the outer wall of the chamber, and partition *a* extending from the outer wall of the chamber to the circular partition.

706,256. HOISTING-MACHINE. LOUIS T. PFOTZ, Philadelphia, Pa., assignor to John B. Reyburn, Philadelphia, Pa. Filed Apr. 15 1901. Serial No. 55,462. (No model.)



Claim.—In a hoisting-machine, a worm, a resilient cushion for the worm, disks interposed between the worm and its resilient cushion, a worm-wheel engaging the worm, chain-wheels thereto removably attached, a divided covering-case, and sheaves of different diameters attached to the worm for its turning.

706,257. TEMPORARY BINDER. CHARLES E. REED and CHESTER A. REED, Worcester, Mass. Filed Oct. 11, 1901. Serial No. 78,328. (No model.)



Claim.—1. In a temporary binder, the combination of front and back covers connected by a back, a rectangular wire frame permanently hinged along one of its longer sides to one of the covers, means for detachably hinging the other longer side of the rectangular frame to the other of said covers, and supporting rods or strips permanently strung at their ends onto the end sections of the wire frame.

2. In a temporary binder, the combination of front and back covers connected by a back, a rectangular wire frame, a piece of sheet metal bent around part of the wire frame to permanently hinge said frame along one of its longer sides to one of the covers, means for detachably hinging the other longer side of the rectangular frame to the other of said covers, and supporting rods or strips having their ends strung onto the shorter sides of the rectangular wire frame.

3. In a temporary binder, the combination of front and back covers connected by a back, an ear arranged on the inside edge of one cover, a wire bent to form a frame and having its ends contained in said ear, ears secured to said wire, an ear secured to the inside edge of the other cover, a pintle passing through said ears, and detachably hinging said wire to this other cover, and a number of supporting-strips arranged on said wire.

706,258. FLOWER SUPPORT OR HOLDER. BERTHA D. SANDERS, New York, N. Y. Filed Jan. 20, 1902. Serial No. 91,158. (No model.)

Claim.—1. The herein-described flower-holder, comprising a flexible strip bent into a series of convolutions, such convolutions combining to form intervening flower-receiving spaces.

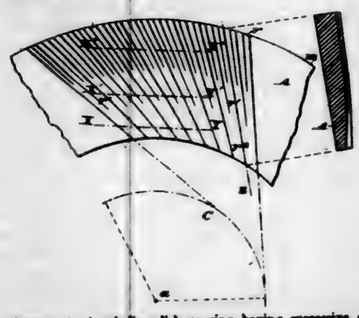
2. The herein-described flower-holder, having a convolute flower-receiving space.

3. The herein-described flower-holder, comprising a central section having a flower-receiving space, and a series of independent segmental sections, each provided with a series of flower-receiving spaces, and arranged in a design about said central section.

4. The herein-described flower-holder, comprising a central section having a flower-receiving space, a plurality of independent segmental sections, each having a flower-receiving space, said independent sections being arranged in a design about said central section and intermediate triangular sections arranged between said segmental sections.

5. The herein-described flower-holder, comprising a flexible strip bent to produce flower-receiving spaces.

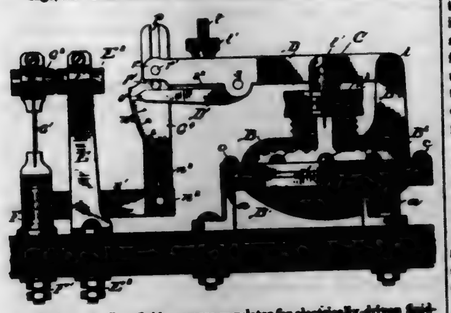
706,259. GROOVING MILLSTONES. JOSEPH SCHWEITZER, Paris, France, assignor to La Société Internationale de Meuneris et de Pantfaction Système Schweitzer, Brussels, Belgium. Filed Dec. 27, 1897. Serial No. 663,304. (No model.)



Claim.—1. A grinding disk or ring having successive groups of combined grooves cut therein all decreasing in size and depth from the inner edge of the ring toward the periphery and all tangential to the same interior circle the center whereof coincides with that of the ring, the principal groove extending the entire width of the ring and being sufficiently wide and deep near the inner edge thereof to receive, cut and crush the grain, and being divided into secondary grooves extending from the periphery about half the width of the ring, said principal grooves being divided into still shorter grooves extending only a short distance from the periphery, said secondary grooves forming the grist and the last-mentioned grooves forming the fine flour.

2. A grinding apparatus provided with identically-dressed grinding disks or rings constructed to receive on that the inclined faces of the grooves approach each other and the diagonal grooves of each disk cross each other, whereby the grain is sheared or clipped and propelled along the grooves toward the periphery of the disks decreasing the time the grain is acted upon and lessening the heating thereof, all of said grooves being tangential to the same interior circle the center whereof coincides with that of the disks and all being of the same form and decreasing in size and depth toward the periphery of the disk, the principal groove extending the entire width of the disk being sufficiently wide and deep near the inner edge thereof to receive cut and crush the grain, and being divided into secondary grooves of less length, said principal grooves being divided into still shorter grooves extending only a short distance from the periphery, the secondary grooves forming the grist and the last-mentioned grooves forming the fine flour.

706,260. PRESSURE-REGULATOR. JACOB L. SCHUERMAN, Chicago, Ill. Filed May 31, 1902. Serial No. 109,605. (No model.)



Claim.—1. In a fluid-pressure regulator for electrically-driven fluid-pressure generators, the combination of a chamber having a spring-pressed movable diaphragm, exposed on one side to the generated fluid-pressure, to be moved thereby, when excessive, against the resistance of the spring, an electric current making and breaking contact, contact-moving lever mechanism connected with the diaphragm, and adjusting mechanism interposed in said lever mechanism for regulating the effect of the diaphragm's movements upon the contact, substantially as and for the purpose set forth.

2. In a fluid-pressure regulator for electrically-driven fluid-pressure generators, the combination with a chamber having a movable diaphragm exposed at one side to the generated fluid-pressure, a spring bearing against the opposite side of said diaphragm, means for increasing and decreasing the resistance of said spring, an electric current making and breaking contact, a lever connected with said diaphragm, a contact-moving lever, and connecting means between said levers adjustable to vary the movement of the said contact-lever with relation to the said diaphragm-lever, substantially as and for the purpose set forth.

3. In a fluid-pressure regulator for electrically-driven fluid-pressure generators, the combination with a chamber having a movable diaphragm exposed at one side to the generated fluid-pressure, a spring bearing against the opposite side of said diaphragm, means for increasing and decreasing the resistance of said spring, an electric current making and breaking contact, a lever D connected with said diaphragm, a finger D' pivoted upon said lever, adjusting means for said finger, a strip in the path of said lever and finger, to be moved thereby alternately in opposite directions, and having a cam, and an electric current making and breaking contact operatively connected with said strip, substantially as and for the purpose set forth.

706,261. COMBINED STOP AND ALARM MECHANISM FOR CARDING-MACHINES. JAMES W. SCOTT, Weston, Me. Filed June 9, 1900. Serial No. 19,798. (No model.)

Claim.—1. The combination with a carding-machine, and stop mechanism, of a flat feed-table over which the sliver is led to the machine, a floating leaf hinged at one edge and supported directly opposite such surface by the sliver passing thereover, and means for effecting the operation of the stop mechanism upon the gravitation of the leaf permitted when the sliver passing over the feed-table is less than the predetermined thickness.

2. The combination with a carding-machine and stop mechanism, of a supporting-surface over which the sliver is led to the machine, a flat floating leaf supported directly opposite such surface by the sliver passing thereover, and means for effecting the operation of the stop mechanism through the movement of the leaf.

3. The combination with a carding-machine, and a feed-table, of electrical controlling mechanism for the carding-machine including a stop-motion circuit, and a circuit-closer having a flat floating leaf disposed directly over and in substantially parallel relation with the table to permit its support upon that portion of the sliver passing over and supported by the feed-table, said circuit-closer being organized to effect the closing of the circuit upon the gravitation of the leaf permitted when the sliver fed to the feed-table is less than a predetermined thickness.

4. The combination with a carding-machine, and a horizontal feed-table, of electrical controlling mechanism for the carding-machine including a stop-motion circuit, a circuit-closer having a hinged leaf formed with a flat smooth under surface imposed upon the flat sliver passing over the feed-table, said leaf serving to cover a considerable portion of the sliver upon the feed-table in order to prevent its extension by slight irregularities of the sliver, and to insure its depression when a considerable amount of the sliver passing over the feed-table is less than a predetermined thickness.

5. The combination with a carding-machine, and a feed-table, of electrical controlling mechanism for the carding-machine including a stop-motion circuit, a circuit-closer having a flat floating leaf disposed directly above the table to be sustained on top of the sliver passing over said table, and an alarm-circuit also controlled by said circuit-closer, whereby when the sliver passing over the table is less than a predetermined thickness, both the stop-motion circuit and the alarm-circuit will be automatically closed to stop the machines and to sound an alarm apprising the operator of the irregular feed of the sliver.

6. In a device of the character described, the combination with stop mechanism and electrical controlling means therefor including a stop-motion circuit, of a circuit-closer consisting of a base having fixed and movable sections hinged together, the movable section being horizontally disposed and connected to the lower end of the fixed section, and contact-plates carried by the fixed and movable sections of the base and designed to be brought into contact upon the downward swinging of the movable section.

7. In a device of the character described, the combination with stop mechanism and electrical controlling means therefor including a stop-motion circuit, of a circuit-closer consisting of a base having fixed and movable sections hinged together, the movable section being in the form of a flat smooth flooring leaf, a contact device mounted upon the upper side of said leaf adjacent to its hinge connection, and a cooperating contact device mounted upon the fixed base-section adjacent to the hinge.

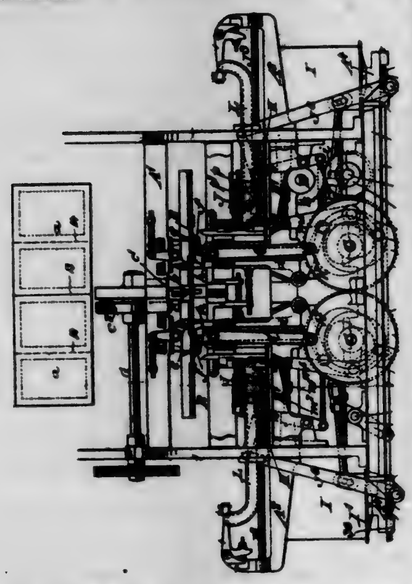
8. In a mechanism of the class described, the combination of a belt-shipper having an electrical releasing device, a stop-motion circuit including said releasing device, and a circuit-closing device consisting of a base having fixed and movable sections hinged together, the movable section being arranged in a substantially horizontal plane for support on top of the sliver, a fixed pendent contact-plate fitted to and offset from the fixed base-section, and a movable contact-plate fitted to the upper side of the movable base-section and having an upturned end overhung by and normally out of contact with the pendent end of the fixed plate, substantially as set forth.

706,262. MACHINERY FOR FOLDING, PACKING, AND STACKING SHEETS OF PAPER, &c. RALPH C. SEYMOUR, South Orange, N. J., assignor to C. B. Cottrell & Sons Company, New York, N. Y., a Corporation of New Jersey. Filed Mar. 20, 1902. Serial No. 100,562. (No model.)

Claim.—1. In a machine for packing and stacking sheets, the combination of a stationary open fence, a reciprocating pusher for pushing sheets against said fence, and a carriage having a to-and-fro movement in relation to said fence for taking packs of sheets from and through said fence and depositing the so-taken packs in a stack, substantially as herein described.

2. In a machine for packing and stacking sheets, the combination of

a stationary open fence, a reciprocating packer for packing sheets against said fence, and a carriage and attached grippers having a to-and-fro movement in relation to said fence for taking packs of sheets from and through said fence and depositing the so-taken packs in a stack, substantially as herein described.



3. The combination with a reciprocating sheet-packer, of a stationary fence having an opening the width of which is not less than that of sheets to be packed against said fence by said packer and the height of which is less than that of such sheets, substantially as herein described.

4. The combination of a stationary open fence, a reciprocating packer for packing sheets against said fence, retaining-fingers pivoted to the sides of said fence for temporarily retaining the so-packed sheets successively against said fence, and means for giving the said fingers a to-and-fro movement, substantially as herein described.

5. The combination with a reciprocating sheet-packer, of a stationary fence having an opening of not less width than that of the sheets to be packed against said fence and having at the sides of said opening in front thereof inwardly-projecting flanges the faces of which are beveled or rounded from their inner edges, substantially as and for the purpose herein described.

6. The combination of a stationary open fence, a reciprocating packer for packing sheets against said fence, retaining-fingers pivoted to the sides of said fence for retaining the so-packed sheets successively against said fence, means for giving said fingers a to-and-fro motion, and flanges on the sides of said fence projecting inwardly therefrom in front of the points of said fingers, substantially as herein described.

7. In a machine for packing and stacking sheets, the combination of a stationary open fence, a reciprocating packer for collecting sheets in packs against said fence, a stacking-receptacle for said packs, a pack-carriage with attached grippers having a to-and-fro motion between said fence and receptacle, means for turning said grippers vertically in said carriage for turning the packs therein from an upright to an approximately horizontal position, and means for opening and closing said grippers, substantially as herein described.

8. In a machine for packing and stacking sheets, the combination of a stationary open fence, a reciprocating packer for collecting sheets in packs against said fence, a stacking-receptacle for said packs, a pack-carriage with pivotally-attached grippers having a to-and-fro motion between said fence and receptacle, means for giving said grippers a lateral pivotal movement on said carriage, and means for opening and closing said grippers, substantially as herein described.

9. In a machine for packing and stacking sheets, the combination of a stationary open fence, a reciprocating packer for collecting sheets in packs against said fence, a stacking-receptacle for said packs, a pack-carriage, grippers having two independent pivotal attachments to said carriage whereby provision is made for both vertical and lateral movements therein, means for producing both said vertical and lateral movements, and means for opening and closing said grippers, substantially as herein described.

10. In a machine for folding, packing and stacking sheets, the combination of a stationary open fence, a reciprocating packer for collecting folded sheets in packs against said fence, a device for folding sheets and depositing them folded between said fence and packer, a receptacle for said packs, a pack-carriage having a to-and-fro motion between said fence and receptacle for taking said packs from said fence to said receptacle, and means for turning the said receptacle between the successive deposits of packs therein, substantially as and for the purpose herein described.

11. In a machine for folding, packing and stacking sheets, the combination of a stationary upright open fence, a reciprocating packer for collecting folded sheets in packs against said fence, a device for folding sheets and depositing them folded between said fence and packer, a receptacle for said packs, a pack-carriage and attached grippers having a to-and-fro motion between said fence and receptacle, means for turning said grippers in said carriage for turning the packs therein from an upright to an approximately horizontal position, means for opening and closing said grippers, and means for turning said receptacles for reversing the direction of the folded edges in successively-received packs, substantially as herein described.

12. In a machine for packing and stacking sheets, the combination of a stationary open fence, a reciprocating packer for collecting sheets in packs against said fence, a stacking-receptacle for said packs, a pack-carriage having grippers so pivoted thereto as to be capable of a lateral motion thereon, means for giving a to-and-fro motion to said carriage between said fence and receptacle, means for producing the lateral movements of the grippers on their pivots, and means for opening and closing the grippers, substantially as herein described.

13. In a machine for packing and stacking sheets, the combination of a stationary open fence, a reciprocating packer for collecting sheets in packs against said fence, a stacking-receptacle for said packs, a pack-carriage having a to-and-fro motion between said fence and receptacle, grippers which are together pivoted in said carriage to turn vertically therein and which are separately pivoted to said carriage to turn laterally thereon, means for turning the grippers vertically in said carriage, means for turning said grippers laterally on said carriage and means for opening and closing said grippers, substantially as herein described.

14. In a machine for packing and stacking sheets, the combination of carriers and stationary guides on which said carriers are capable of a to-and-fro movement, a rock-shaft and bearings therefor on said carriers, two gripper-levers pivoted to said rock-shaft to move laterally with respect to said to-and-fro movement, corresponding gripper-jaws one on each lever and one affixed to the rock-shaft, and gripper-jaws one on each of said levers movable to and from said corresponding gripper-jaws, substantially as herein described.

15. In a machine for packing sheets and depositing them in packs, the combination with a pack-carriage, of two sets of grippers attached to said carriage for taking opposite sides of a pack, springs on the carriage for opening said grippers, detents for holding the grippers closed, trip-levers for disengaging said detents, and tappets on the carriage for actuating said trip-levers to effect said disengagement, substantially as herein described.

16. In a machine for packing sheets and depositing them in packs, the combination with a pack-carriage, of two sets of grippers and pivots which attach said grippers to said carriage and on which said grippers move laterally to said carriage for taking opposite sides of a pack, springs on said carriage for moving the grippers outward on said pivots, detents between said grippers and the carriage for holding said grippers toward the sides of the pack, trip-levers for disengaging said detents, and tappets on the carriage for actuating said trip-levers to effect said disengagement, substantially as herein described.

17. In a machine for packing sheets and depositing them in packs, the combination with a pack-carriage, two sets of grippers and pivots which attach said grippers to said carriage and on which said grippers move laterally to said carriage for taking opposite sides of a pack, springs on said carriage for moving the grippers outward on said pivots, detents between said grippers and the carriage for holding said grippers toward the sides of the pack, springs on the carriage for opening said grippers, detents for holding said grippers closed, trip-levers for disengaging both of said detents, and tappets on the carriage for actuating said trip-levers to effect said disengagement, substantially as herein described.

18. In a machine for packing sheets and depositing them in packs, the combination with a pack-carriage, of two sets of grippers attached to said carriage for taking opposite sides of a pack, springs on the carriage for opening said grippers, a spring for closing said grippers and a cam for actuating and controlling said spring to overcome the action of the first-mentioned springs, substantially as herein described.

19. In a machine for packing sheets and depositing them in packs, the combination with a pack-carriage, of two sets of grippers and pivots which attach said grippers to said carriage and on which said grippers move laterally to said carriage for taking opposite sides of a pack, springs on said carriage for moving the grippers outward on said pivots, detents between said grippers and the carriage for holding said grippers toward the sides of the pack, springs on the carriage for opening said grippers, detents for holding said grippers closed, trip-levers for disengaging both of said detents, tappets on the carriage for actuating said trip-levers to effect said disengagement, and a cam for actuating said springs, substantially as herein described.

20. In a machine for packing sheets and depositing them in packs, the combination with a pack-carriage and attached grippers for taking opposite sides of a pack, a spring and connected mechanism outside of the carriage for opening said grippers, and a rotary cam outside of said carriage for first producing an expansive tension of said spring and afterward suddenly releasing it to produce the said opening, substantially as herein described.

21. In a machine for packing sheets and depositing them in packs, the combination with grippers for taking the sides of the packs and a spring for opening said grippers, of a spring *f* for closing said grippers, a fixed abutment f^4 for said spring, a trip-lever f^3, a sliding tappet-bar f^{11}, connections between said lever and bar and between said lever and spring, a rotary cam f^7 for operating on said trip-lever for producing first the tension of the spring and afterward the tripping of the lever to produce the closing of the grippers, and a detent for holding the grippers closed, all substantially as herein described.

22. In a machine for packing sheets and depositing them in packs, the combination of two reciprocating carriers and guides therefor on which they have a to-and-fro movement, a rock-shaft and bearings therefor on said carriers, two sets of pack-grippers pivoted to said rock-shaft to move laterally to said to-and-fro movement, means for producing said lateral movement, means for opening and closing the grippers and means for turning the said rock-shaft in said bearings, substantially as and for the purpose herein described.

23. In a machine for packing sheets and depositing them in packs, the combination with a pack-carriage, of gripper-levers pivoted to said carriage, one on each side thereof, to be capable of moving laterally to and fro thereon, gripper-jaws formed on each of said levers, a gripper-rod sliding longitudinally within said lever and furnished with a gripper-jaw opposite that on the corresponding lever, springs applied between said rods and their respective levers for opening the gripper-jaws, and a detent on said lever for engaging with said rod for keeping the grippers closed, substantially as herein described.

24. In a machine for packing sheets and depositing them in packs, the combination with a reciprocating pack-carriage, of gripper-levers one at each side of the carriage and each furnished with a pair of gripper-jaws, pivots one for each lever on which it is capable of moving laterally to the carriage, arms one on each pivot, fixed stops one for each of said arms for the purpose of producing the movement of the gripper-levers in an inward direction by the movement of the carriage for taking the packs, and detents between said levers and carriage for locking the levers in said direction, substantially as herein described.

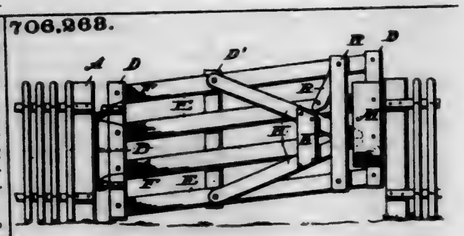
25. In a machine for packing and stacking sheets, the combination of carriers and stationary guides on which they are capable of a to-and-fro movement, a rock-shaft and bearings therefor in said carriers, grippers on said rock-shaft for taking opposite sides of packs of sheets, and means for turning said rock-shaft and grippers to change the position of the pack in the grippers from an upright to a substantially horizontal, substantially as herein described.

26. In a machine for packing and stacking sheets, the combination of carriers and stationary guides on which they are capable of a to-and-fro movement, a rock-shaft and bearings therefor in said carriers, grippers on said rock-shaft for taking opposite sides of a pack of sheets, a stationary cam, and an arm on the rock-shaft engaging with said cam for producing the turning of said rock-shaft and grippers to change the position of the pack in the grippers from upright to substantially horizontal and vice versa by the to-and-fro movement of the carriage, substantially as herein described.

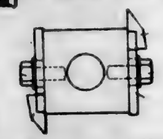
706,268. GATE. George W. Green, Thornton, N. Y. Filed Apr. 24, 1902. Serial No. 104,468. (No model.)

Claim.—A folding panel-gate comprising the longitudinal strips with end and intermediate pivotal, cross-bars, the plate M fastened to the cross-bar at the free end of the gate, the bars H pivoted to the top and bottom strips of the gate, and fastened together at their forward ends, suitably bowed, and guided behind said plate M and one of the said cross-bars, and a pivoted brace E adapted to contact with one of said bars H, as shown and for the purpose set forth.

706,268.



706,264. CUTTING-TOOL FOR PLANING-MACHINES. Ransome H. Slater, Auckland, New Zealand. Filed Mar. 18, 1902. Serial No. 98,389. (No model.)



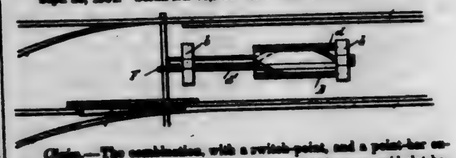
Claim.—The combination of a cutter-holder having means by which it may be secured to the cutter-block of a planing-machine and a cutter dovetailed into said holder substantially as and for the purpose specified.

706,265. MEANS FOR SECURING WHEELS ON SHAFTS. Clarence C. Shalley, Manitowoc, Wis. Filed June 2, 1902. Serial No. 109,851. (No model.)

Claim.—1. The combination with a wheel, of a rotatable shaft having a tapering bearing, a cylindrical bearing of equal diameter throughout its length and terminating in a screw-threaded extension, a collar engaging the tapering bearing and a screw-nut engaging the screw-threaded extension, said collar and nut providing means for holding the wheel upon the shaft, substantially as and for the purpose described.

2. A rotatable driving-shaft having a tapering bearing, an outwardly-extending cylindrical bearing terminating in a screw-threaded extension having a projection thereon, a key engaging therewith, a wheel supported upon the cylindrical bearing, a collar upon the tapering bearing, and a nut engaging the screw-threaded extension, substantially as and for the purposes set forth.

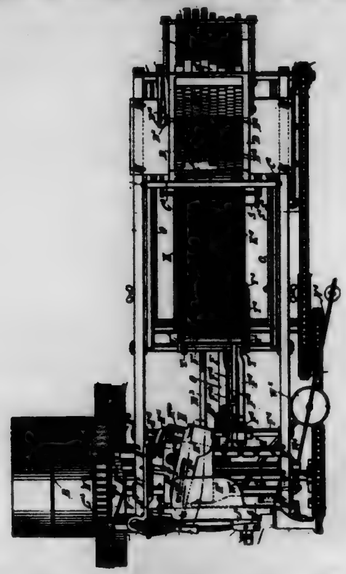
706,266. SWITCH. Gustave H. Sitzer, Boston, Mass. Filed Sept. 26, 1901. Serial No. 76,542. (No model.)



Claim.—The combination, with a switch-point, and a point-bar engaging with it and provided with a slot at its middle part; said slot being arranged vertically and open at the lower edge of the said bar of a ling arranged vertically and open at the lower edge of the said bar of a spirally-grooved cylinder provided with a shaft and journaled longitudinally between the rails, a crank-pin projecting from one end of the said shaft and engaging with the said slot of the point-bar, and a switch-bar

carried by the car and engaging with the said cylinder, substantially as set forth.

706,267. AUTOMATIC CIGAR-MAKING MACHINE. BENJAMIN H. SEAVEY, Bridgewater, and THOMAS H. KELLER, Lima, Pa. Filed Aug. 30, 1900. Renewed May 3, 1901. Serial No. 59,260. (No model.)



Claim.—1. An automatic cigar-making machine, comprising a compacting device for forming the loose tobacco in measured quantities into a compacted filler, a rolling device receiving the compacted filler of tobacco from the said compacting device, to roll the filler and secure the binder around it to form the bunch, and a wrapping mechanism receiving the bunch from the said rolling device and wrapping the wrapper around the bunch and securing it in place, as set forth.

2. An automatic cigar-making machine, comprising a compacting device for forming the loose tobacco in measured quantities into a compacted filler, a rolling device receiving the compacted filler of tobacco from the said compacting device, to roll the filler and secure the binder around it to form the bunch, and a wrapping mechanism into which the bunch is discharged by the said rolling device, and a wrapping mechanism into which the bunch is discharged by the said transferring device, the said wrapping mechanism wrapping the wrapper around the bunch and securing it in place, as set forth.

3. An automatic cigar-making machine, comprising a compacting device for forming the loose tobacco in measured quantities into a compacted filler, a rolling device receiving the compacted filler of tobacco from the said compacting device, to roll the filler and secure the binder around it to form the bunch, a transferring device into which the bunch is discharged by the said rolling device, a cutting device on the said transferring device to cut off the ends of the bunch, and a wrapping mechanism into which the bunch is discharged by the said transferring device, the said wrapping mechanism wrapping the wrapper around the bunch and securing it in place, as set forth.

4. An automatic cigar-making machine, comprising a compacting device for forming the loose tobacco in measured quantities into a compacted filler, a rolling device receiving the compacted filler of tobacco from the said compacting device, to roll the filler and secure the binder around it to form the bunch, a wrapping mechanism receiving the bunch from the said rolling device and wrapping the wrapper around the bunch and securing it in place, and means for cleaning the head portion of the said wrapping mechanism after a cigar is discharged therefrom, as set forth.

5. An automatic cigar-making machine, comprising a compacting device for forming the loose tobacco in measured quantities into a compacted filler, a rolling device receiving the compacted filler of tobacco from the said compacting device, to roll the filler and secure the binder around it to form the bunch, and a wrapping mechanism receiving the bunch from the said rolling device and wrapping the wrapper around the bunch and securing it in place, the said wrapping mechanism having a wrapper-smoothing device for smoothing the wrapper on the bunch during the wrapping process, as set forth.

6. An automatic cigar-making machine, comprising a compacting device for forming the loose tobacco in measured quantities into a compacted filler, a rolling device receiving the compacted filler of tobacco from the said compacting device, to roll the filler and secure the binder around it to form the bunch, and a wrapping mechanism receiving the bunch from the said rolling device and wrapping the wrapper around the bunch and securing it in place, the said wrapping mechanism having a cut-off device for cutting off the butt end of the wrapper during the wrapping process, as set forth.

7. An automatic cigar-making machine, comprising a compacting device for forming the loose tobacco in measured quantities into a compacted filler, a rolling device receiving the compacted filler of tobacco from the said compacting device, to roll the filler and secure the binder around it to form the bunch, and a wrapping mechanism receiving the bunch from the said rolling device and wrapping the wrapper around the bunch and securing it in place, the said wrapping device having means for cutting the head end of the wrapper previously to wrapping the head end onto the bunch, as set forth.

8. An automatic cigar-making machine, comprising a compacting device for forming the loose tobacco in measured quantities into a compacted filler, a rolling device receiving the compacted filler of tobacco from the said compacting device, to roll the filler and secure the binder around it to form the bunch, and a wrapping mechanism receiving the bunch from the said rolling device and wrapping the wrapper around the bunch and securing it in place, the said wrapping device having a cutting device for forming a point on the head end of the wrapper, and a pasting device for delivering paste to the head end of the wrapper after the said end is cut to a point, as set forth.

9. An automatic cigar-making machine, controlled by a definite revolving agent, consisting of a compacting device for forming the loose or scrap tobacco in measured quantities into a compacted filler, a rolling device for which the said compacting device forms the feed, said rolling device rolling the filler and securing the binder around it, to form the bunch, a wrapping mechanism receiving the bunch from said rolling device and placing the wrapper around it, means for actuating said devices and mechanism in unison, and a main or power shaft for said means, as set forth.

10. An automatic cigar-making machine controlled by a definite revolving agent, consisting of a compacting device for forming the loose or scrap tobacco in measured quantities into a compacted filler, a rolling device for which the said compacting device forms the feed, said rolling device rolling the filler and securing the binder around it to form the bunch, a transferring device, a wrapping mechanism receiving the bunch by the said transferring device from the said rolling device, means for actuating the said devices, and a main or power shaft for the said means, as set forth.

11. An automatic cigar-making machine having a hopper for containing loose or scrap tobacco, a compacting-pocket at the discharge-opening of said hopper, pushers mounted to slide independently one of the other on the bottom of the said hopper for pushing the tobacco into said pocket and packing it therein, and means for imparting movement to the said pushers, as set forth.

12. An automatic cigar-making machine having a hopper for containing loose or scrap tobacco, a compacting-pocket extending across the discharge-opening of said hopper, and pushers mounted to slide on the bottom of the hopper toward and from said pocket, said pushers having ratchet-teeth on their upper faces, as set forth.

13. An automatic cigar-making machine having a hopper with an inclined bottom and arranged to contain loose or scrap tobacco, a compacting-pocket extending across the discharge-opening of said hopper, and spring-pressed pushers arranged on said hopper-bottom and mounted to slide successively toward or from said pocket, said pushers being formed at their upper surfaces with ratchet-teeth, for straightening out the tobacco in the hopper prior to pushing the same into said pocket, as set forth.

14. An automatic cigar-making machine having a hopper for containing loose or scrap tobacco, a compacting-pocket extending across the discharge-opening of said hopper, pushers mounted to slide on the bottom of the hopper, and springs for forcing the pushers toward said opening, to push the tobacco into said pocket and pack it therein, as set forth.

15. An automatic cigar-making machine having a hopper for containing loose or scrap tobacco, a compacting-pocket extending across the discharge-opening of said hopper, pushers mounted to slide on the bottom of the hopper, springs for forcing the pushers toward said opening, to push the tobacco into said pocket and pack it therein, and cam-arms or wipers for engaging said pushers and moving the same outward against the tension of said springs, as set forth.

16. An automatic cigar-making machine having a hopper for containing loose or scrap tobacco, a compacting-pocket extending across the discharge-opening of said hopper, pushers mounted to slide on the bottom of the hopper, springs for forcing the pushers toward said opening, to push the tobacco into said pocket and pack it therein, a revolvable cam-shaft, and cam-arms or wipers thereon, and adapted to engage depending arms on said pushers to move the latter against the springs and from said hopper discharge-opening, as set forth.

17. An automatic cigar-making machine having a hopper for containing loose or scrap tobacco, a compacting-pocket extending across the discharge-opening of said hopper, pushers mounted to slide on the bottom of the hopper, springs for forcing the pushers toward said opening, to push the tobacco into said pocket and pack it therein, a revolvable cam-shaft, and cam-arms or wipers thereon, and adapted to engage depending arms on said pushers, to move the latter against the springs and from said hopper discharge-opening, said cam-arms being set at an angle to one another, to impart a successive sliding motion to the pushers, as set forth.

18. An automatic cigar-making machine having a hopper for containing loose or scrap tobacco, a compacting-pocket at the discharge-opening of the hopper, pushers mounted to slide independently one of the other on the bottom of the hopper for pushing the tobacco into said pocket and packing it therein, means for imparting movement to said pushers, and an agitator in the hopper above the said pushers for keeping the tobacco therein loose and for insuring proper feed of the tobacco into the pocket by the pushers, as set forth.

19. An automatic cigar-making machine having a hopper for containing loose or scrap tobacco, a compacting-pocket extending across the discharge-opening of said hopper, pushers mounted to slide on the bottom of the hopper, an agitator in said hopper, and means for intermittently actuating said pushers and said agitator in unison, as set forth.

20. An automatic cigar-making machine having a hopper for containing loose or scrap tobacco, a compacting-pocket extending across the discharge-opening of said hopper, pushers mounted to slide on the bottom of the hopper, springs for forcing the pushers toward said opening and pushing the tobacco into said pocket and packing it therein, a revolvable cam-shaft, cam-arms or wipers thereon for engaging arms on said pushers and moving the latter against the springs and from said hopper discharge-opening, agitator-arms in said hopper, a rock-shaft carrying said arms, and a connection between said cam-shaft and said rock-shaft, for actuating the latter from the cam-shaft, as set forth.

21. An automatic cigar-making machine having a hopper for containing loose or scrap tobacco, a compacting-pocket extending across the discharge-opening of said hopper, pushers mounted to slide on the bottom of the hopper, springs for forcing the pushers toward said opening and pushing the tobacco into said pocket and packing it therein, a revolvable cam-shaft, cam-arms or wipers thereon for engaging arms on said pushers and moving the latter against the springs and from said hopper discharge-opening, agitator-arms in said hopper, a rock-shaft carrying said arms, and a connection between said cam-shaft and said rock-shaft, for actuating the latter from the cam-shaft, said connection comprising an eccentric on the cam-shaft, and an arm on the rock-shaft and pivotally connected with the eccentric-rod of said eccentric, as set forth.

22. An automatic cigar-making machine having a hopper for containing loose or scrap tobacco, compacting-pocket movable to and from the discharge-opening of said hopper, and a knife movable on said hopper over the discharge-opening thereof, to cut off the tobacco in the hopper and to close the said discharge-opening, the said knife also forming a side for the said pocket when the latter is moving from and to said discharge-opening, as set forth.

23. An automatic cigar-making machine having a compacting-pocket into which tobacco is mechanically packed, said pocket having a hinged bottom and an adjustable top, for giving the desired shape to said top, as set forth.

24. An automatic cigar-making machine having a compacting-pocket into which tobacco is mechanically packed, said pocket having a flexible top, and means for giving the desired curvature to the top, as set forth.

25. An automatic cigar-making machine having a compacting-pocket into which tobacco is mechanically packed, said pocket comprising a hinged bottom, a knife movable over the inlet to said pocket and arranged to form one side thereof when closed, and an adjustable top for the pocket, as set forth.

26. An automatic cigar-making machine having a compacting-pocket into which tobacco is mechanically packed, said pocket comprising a hinged bottom, a knife movable over the inlet to the pocket and arranged to form one side thereof when closed, a flexible top, and means for supporting said top and changing the curvature thereof, as set forth.

27. An automatic cigar-making machine having a compacting-pocket into which tobacco is mechanically packed, said pocket comprising a hinged bottom, a knife movable over the inlet to the pocket and arranged to form one side thereof when closed, an adjustable top, and means for imparting a swinging motion to said hinged bottom, to open and close the same, as set forth.

28. An automatic cigar-making machine having a hopper provided with a discharge-opening, a slide arranged to reciprocate on the side of the hopper, a pocket-carrier movable on said slide, and a pocket carried partly by said pocket-carrier and partly by said slide, as set forth.

29. An automatic cigar-making machine having a hopper provided with a discharge-opening, a slide mounted to reciprocate on the side of the hopper, a pocket-carrier movable on said slide, a pocket carried partly by said pocket-carrier and partly by said slide, means for imparting a reciprocating motion to said slide, and means controlled by the slide, for imparting a reciprocating motion to the pocket-carrier, as set forth.

30. An automatic cigar-making machine having a hopper provided with a discharge-opening, a slide mounted to reciprocate on the side of the hopper, a pocket-carrier movable on said slide, a pocket carried partly by said pocket-carrier and partly by said slide, said pocket comprising a knife fixed on said slide, a bottom hinged to said carrier, and a top adjustably carried by said pocket-carrier, as set forth.

31. An automatic cigar-making machine having a hopper provided with a discharge-opening, a slide mounted to reciprocate on the side of the hopper, a pocket-carrier movable on said slide, a pocket carried partly by said pocket-carrier and partly by said slide, said pocket comprising a knife fixed on said slide, a bottom hinged to said carrier, a top adjustably carried by said pocket-carrier, and means for imparting a swinging motion to said hinged bottom, to open and close the same, as set forth.

32. An automatic cigar-making machine having a hopper provided with a discharge-opening, a slide mounted to reciprocate on the side of the hopper, a pocket-carrier movable on said slide, a pocket carried partly by said pocket-carrier and partly by said slide, said pocket comprising a knife fixed on said slide, a bottom hinged to said carrier, a top adjustably carried by said pocket-carrier, and means for imparting a swinging motion to said hinged bottom, to open and close the same, said means comprising arms having lugs, and fixed pins for engagement by the lugs, as set forth.

33. An automatic cigar-making machine having a hopper, a slide reciprocating on the side of the said hopper, a pocket-carrier movable on said slide, a pocket comprising a knife fixed on said slide, a bottom hinged to said pocket-carrier, a flexible top adjustably carried by said pocket-carrier, and means for imparting sliding movement to said pocket-carrier, as set forth.

34. An automatic cigar-making machine having a hopper, a slide reciprocating on the side of the said hopper, a pocket-carrier movable on said slide, a pocket comprising a knife fixed on said slide, a bottom hinged to said pocket-carrier, a flexible top adjustably carried by said pocket-carrier, and means for imparting a sliding movement to said pocket-carrier, said means being controlled by said slide, as set forth.

35. An automatic cigar-making machine having a hopper, a slide reciprocating on the side of the said hopper, a pocket-carrier movable on said slide, a pocket comprising a knife fixed on said slide, a bottom hinged to said pocket-carrier, and means for imparting sliding movement to said pocket-carrier, and comprising bell-crank levers fulcrumed on the slide and engaging said carrier, and cam-grooves on said hopper, as set forth.

36. An automatic cigar-making machine having a hopper, a slide reciprocating on the side of the said hopper, a pocket-carrier movable on said slide, a pocket comprising a knife fixed on said slide, a bottom hinged to said pocket, bell-crank levers fulcrumed on the slide and engaging said carrier and shoes in cam-grooves on the said hopper for controlling the movement of the bell-crank levers, as set forth.

37. An automatic cigar-making machine having a hopper, a cut-off knife for the discharge end of said hopper, pushers in the hopper for feeding tobacco to said discharge end, and means for imparting movement to said cut-off knife and to said pushers, to actuate the latter while the cut-off knife is in an open position, and to move and hold the knife in a closed position when the pushers are at rest, as set forth.

38. An automatic cigar-making machine having a hopper with a discharge-opening, a compacting-pocket movable on the side of said hopper and having a cut-off knife and a movable bottom, the cut-off knife being arranged to close the said discharge-opening and to form a side of the pocket, an apron, and means for moving said pocket from said opening into engagement with said apron, to form a pocket therein for the reception of the compacted filler contained in said compacting-pocket, the said knife closing the discharge-opening during the movement of the pocket from and to said opening, as set forth.

39. An automatic cigar-making machine having a hopper with a discharge-opening, a compacting-pocket movable on the side of said hopper and having a cut-off knife and a movable bottom, the cut-off knife being arranged to close the said discharge-opening and to form a side of the pocket, an apron, means for moving said pocket from said opening into engagement with said apron, to form a pocket therein for the reception of the compacted filler contained in said compacting-pocket, the said

knife closing the discharge-opening during the movement of the pocket from end to said opening, and means for moving said bottom after the apron-pocket is formed to open the compacting-pocket, to drop the compacted filler into the apron-pocket, as set forth.

40. An automatic cigar-making machine having a hopper with a discharge-opening, a compacting-pocket movable on the side of said hopper and having a cut-off knife and a movable bottom, the cut-off knife being arranged to close the said discharge-opening and to form a side of the pocket, an apron, means for moving said pocket from said opening into engagement with said apron, to form a pocket therein for the reception of the compacted filler contained in said compacting-pocket, the said knife closing the discharge-opening during the movement of the pocket from end to said opening, and means for imparting supplementary movement to the knife independent of the pocket, as set forth.

41. An automatic cigar-making machine having a table with a recess, an apron extending over the said table, a compacting-pocket having a hinged bottom, means for moving said compacting-pocket into engagement with said apron by said table-recess, to force the apron into the recess and thereby produce a pocket in the apron, and means for swinging the bottom open while in contact with the apron, to allow the compacted filler to pass into the apron-pocket, without the compacted filler opening up, as set forth.

42. An automatic cigar-making machine having a perforated table, an apron, and a suction device for holding the apron by suction to said table, the suction taking place through the perforations in the said table as set forth.

43. An automatic cigar-making machine having a table, an apron having an aperture, and a suction device for holding the apron by suction to the table and for holding a binder by suction to the apron at said aperture, as set forth.

44. An automatic cigar-making machine having a perforated table, an apron extending over the table, and a suction-chamber in communication with the perforations in the table, to hold the apron by suction to the table, said apron having an aperture in register with one of the perforations in the table, to hold one end of a binder by suction to the apron, as set forth.

45. An automatic cigar-making machine having a perforated table, an apron over said table and held thereon by suction through the perforations of the table, the apron having a pocket for containing a filler of tobacco, a reciprocating carriage, a roller journaled on said carriage and over which passes the apron, as set forth.

46. An automatic cigar-making machine having a perforated table, an apron over said table and held thereon by suction through the perforations of the table, the apron having a pocket for containing a filler of tobacco, a reciprocating carriage, a roller journaled on said carriage and over which passes the apron, and a cut-off plate on said carriage, for covering up the perforations of the table as the apron leaves the same during the forward movement of the carriage, as set forth.

47. An automatic cigar-making machine having a table, an apron over said table, and having a pocket for containing a filler, a reciprocating carriage, a roller supported by the carriage and engaged by the apron, and a finger supported from the carriage, and adapted to engage a binder and hold the latter to the apron and start it onto the filler, said finger being mounted to swing on one end thereof as the fulcrum, as set forth.

48. An automatic cigar-making machine having a finger for engagement with a binder and mounted to swing, one end of the finger being the fulcrum, as set forth.

49. An automatic cigar-making machine having an arm mounted to swing, means for moving the arm endwise and a finger fulcrumed at one end on said arm, to allow the finger to swing, said finger being adapted to engage one end of the binder and hold the latter to the rolling-apron, as set forth.

50. An automatic cigar-making machine having an arm mounted to swing, means for moving the arm endwise, a finger having a head loosely mounted on said arm, and a spring carried by the arm, and engaging said head, as set forth.

51. An automatic cigar-making machine having a table, an apron over the table and provided with a pocket for containing a filler, a reciprocating carriage, a roller carried thereby and engaged by said apron, an arm moving with said carriage and arranged to swing toward or from said apron, and a finger carried by said arm and adapted to engage the binder on said apron, as set forth.

52. An automatic cigar-making machine having a table, an apron over the table and provided with a pocket for containing a filler, a reciprocating carriage, a roller carried thereby and engaged by said apron, an arm moving with said carriage and arranged to swing toward or from said apron, a finger carried by said arm and adapted to engage the binder on said apron, and means for imparting a swinging motion to said arm from said carriage, as set forth.

53. An automatic cigar-making machine having a reciprocating carriage, a slide mounted thereon, an arm fulcrumed on said slide and carrying a finger for engaging the binder, means for imparting motion to said slide independently of the movement of the carriage, and means for imparting a swinging motion to said arm, as set forth.

54. An automatic cigar-making machine having a reciprocating carriage, a slide mounted thereon, an arm fulcrumed on said slide and carrying a finger for engaging a pointer, a pin extending from the fulcrum end of said arm, a link pivotally connected with said slide and having a connect engaged by said pin, a segmental gear-wheel connected with said link and means for imparting an intermittent rotary motion to said segmental gear-wheel, as set forth.

55. An automatic cigar-making machine having a reciprocating carriage, a slide mounted thereon, an arm fulcrumed on said slide and carrying a finger for engaging a pointer, a pin extending from the fulcrum end of said arm, a link pivotally connected with said slide and having a connect engaged by said pin, a segmental gear-wheel connected with said link and having an intermittent rotary motion, and cam of pins for engaging said segmental gear-wheel, as set forth.

56. An automatic cigar-making machine having a reciprocating carriage with a guideway having a curved end, a slide in said guideway, an arm fulcrumed on said slide and carrying a finger for engaging a binder, a pin extending from the fulcrum end of said arm, a link pivotally connected with said slide and having a cam-slot engaged by said pin, a segmental gear-wheel connected with the link and means for imparting an intermittent rotary motion to the said segmental gear-wheel, as set forth.

57. An automatic cigar-making machine having a slide mounted to move in a guideway with a curved end, an arm fulcrumed on said slide and carrying a finger for engaging a binder, and means, substantially as described, for imparting a reciprocating movement to said slide, and at the same time a swinging motion to said arm, as set forth.

58. An automatic cigar-making machine having a reciprocating carriage, a roller moving with said carriage, and fixed guideways of different shape and engaged by the ends of said roller, so that upon reciprocating the carriage the roller moves with it and rocks in a plane at an angle to the plane of movement of the carriage, as set forth.

59. An automatic cigar-making machine having a carriage, and a roller moving with the carriage and having a rocking motion in a plane at an angle to the plane in which the carriage moves, as set forth.

60. An automatic cigar-making machine having a carriage, and a roller moving with the carriage and having a rocking motion in a plane at an angle to the plane in which the carriage moves, said roller having a concave face, as set forth.

61. An automatic cigar-making machine having an apron, a roller over which the apron passes, to roll a filler, and to roll a binder around said filler, said roller having a curved shaft, collars of different diameters and mounted to turn loosely on said shaft, a carriage having a reciprocating movement, arms pivoted on said carriage and engaging said shaft, and fixed guideways of different shape and engaged by the ends of said roller-shaft, to impart a rocking motion to the roller in a plane at an angle to the plane of movement of the carriage, as set forth.

62. An automatic cigar-making machine having a reciprocating carriage, a fixed table, an apron over said table, a roller having a curved shaft, collars mounted to turn thereon, arms pivoted to said carriage and supporting said shaft, and fixed guideways of different shape and engaged by the ends of said shaft, as set forth.

63. An automatic cigar-making machine having a bunch-forming device, a transferring device into which discharges said bunch-forming device, a wrapping mechanism into which discharges said transferring device, a driven shaft, and means for actuating in unison said bunch-forming device, the transferring device and the wrapping mechanism, as set forth.

64. An automatic cigar-making machine having a lever with a fixed plate, means for imparting a swinging motion to said lever, and a plurality of levers fulcrumed on said first-named lever and moving with the same, and having plates forming in conjunction with the first-named plate a pocket, as set forth.

65. An automatic cigar-making machine having a lever with a fixed plate, means for imparting a swinging motion to said lever, a plurality of levers fulcrumed on said first-named lever and moving with the same, and having plates forming in conjunction with the first-named plate a pocket, for receiving and holding the filler, one of the plates having an ejecting-plate for forcing the filler out of the pocket, and means for operating the said ejecting-plate, as set forth.

66. An automatic cigar-making machine having a lever with a fixed plate, means for imparting a swinging motion to said lever, a plurality of levers fulcrumed on said first-named lever and moving with the same, and having plates forming in conjunction with the first-named plate a pocket, and means for actuating the last-named levers independently of the first-named lever, as set forth.

67. An automatic cigar-making machine having a transferring-pocket

with a plurality of plates, two of which form opposite sides and one the bottom of the pocket, one of said side plates having movement toward the other plates, and means for operating the said movable side plate to close or open the pocket, as set forth.

68. An automatic cigar-making machine having a transferring-pocket, comprising a plurality of plates, two of which form opposite sides and one the bottom of the pocket, the bottom plate having movement between said side plates to eject the filler from the pocket, as set forth.

69. An automatic cigar-making machine having a transferring-pocket, comprising a plurality of plates, two of which form opposite sides and one the bottom of the pocket, the bottom plate having movement between said side plates to eject the filler from the pocket, and means, substantially as described, for imparting movement to the said plates, as set forth.

70. An automatic cigar-making machine having a wrapping mechanism, a transferring device for holding a bunch, a shaft, and means actuated from said shaft and connected with and actuating said wrapping mechanism and said transferring device in unison, to discharge the bunch from said transferring device to the wrapping mechanism, as set forth.

71. An automatic cigar-making machine having a wrapping mechanism, a transferring device for holding a bunch, a shaft, and means actuated from said shaft and connected with and actuating said wrapping mechanism and said transferring device in unison, to discharge the bunch from said transferring device to the wrapping mechanism, and to cause said wrapping mechanism and transferring device to automatically open for the transferring device to discharge the bunch into the open wrapping mechanism, as set forth.

72. An automatic cigar-making machine having a fixed wrapper-platform, means for rolling a wrapper around a bunch, a slide having an intermittent sliding movement lengthwise of said means, a platform pivoted to a fixed part and extending partly under said fixed platform, a connection between said slide and said pivoted platform, to impart a swinging motion to the latter, a brush hinged to the swinging platform for holding the head of the wrapper in place on the swinging platform, revolving brushes operating in conjunction with said wrapping means, an arm pivoted on said slide carrying said revolving brushes, and controlling the movement of said platform-brush, and means for imparting movement to said arm, as set forth.

73. An automatic cigar-making machine having a fixed wrapper-platform, means for rolling a wrapper around a bunch, a slide having an intermittent sliding movement lengthwise of said means, a platform pivoted to a fixed part and extending partly under said fixed platform, a connection between said slide and said pivoted platform, to impart a swinging motion to the latter, a brush hinged to the swinging platform for holding the head of the wrapper in place on the swinging platform, revolving brushes operating in conjunction with said wrapping means, an arm pivoted on said slide carrying said revolving brushes, and controlling the movement of said platform-brush, a driven cam-wheel, an operative connection between said cam-wheel and said slide, to impart an intermittent sliding motion to the slide, and an operative connection between said cam-wheel and said brush-carrying arm, as set forth.

74. An automatic cigar-making machine having a plurality of wrapping-rollers forming a pocket for receiving a bunch and wrapping a wrapper around said bunch, a slide arranged to move lengthwise of said wrapping-rollers, a wrapper-platform for feeding the wrapper to said rollers and pivoted to a fixed part, a connection between the slide and platform for imparting a swinging motion to the latter, a shoe carried by said slide, a shaft having a double spiral groove engaged by said shoe, and a driven cam gear-wheel for intermittently rotating said shaft, as set forth.

75. An automatic cigar-making machine having a plurality of wrapping-rollers forming a pocket for receiving a bunch and wrapping a wrapper around said bunch, a slide arranged to move lengthwise of said wrapping-rollers, a wrapper-platform for feeding the wrapper to said rollers and pivoted to a fixed part, a connection between the slide and platform for imparting a swinging motion to the latter, a shoe carried by said slide, a shaft having a double spiral groove engaged by said shoe, a driven cam gear-wheel for intermittently rotating said shaft, brushes for brushing the wrapper tight around the bunch, and an arm pivoted on said slide and carrying said brushes, said arm receiving an intermittent swinging motion from said cam gear-wheel, as set forth.

76. An automatic cigar-making machine having a plurality of wrapping-rollers forming a pocket for receiving a bunch and wrapping a wrapper around said bunch, a slide arranged to move lengthwise of said wrapping-rollers, a wrapper-platform for feeding the wrapper to said rollers and pivoted to a fixed part, a connection between the slide and platform for imparting a swinging motion to the latter, a shoe carried by said slide, a shaft having a double spiral groove engaged by said shoe, a driven cam gear-wheel for intermittently rotating said shaft, brushes for brushing the wrapper tight around the bunch, an arm pivoted on said slide and carrying said brushes, said arm receiving an intermittent swinging motion from said cam gear-wheel, and operative connections between said cam gear-wheel and said shaft, and between the cam gear-wheel and said arm, as set forth.

77. An automatic cigar-making machine having a plurality of wrapping-rollers forming a pocket for receiving a bunch and wrapping a wrapper around said bunch, a slide arranged to move lengthwise of said wrapping-rollers, a wrapper-platform for feeding the wrapper to said rollers and pivoted to a fixed part, a connection between the slide and platform for imparting a swinging motion to the latter, a shoe carried by said slide, a shaft having a double spiral groove engaged by said shoe, a driven cam gear-wheel for intermittently rotating said shaft, brushes for brushing the wrapper tight around the bunch, an arm pivoted on said slide and carrying said brushes, said arm receiving an intermittent swinging motion from said cam gear-wheel, and means for intermittently rotating said brushes from said shaft, as set forth.

78. An automatic cigar-making machine having a plurality of wrapping-rollers forming a pocket for receiving a bunch and wrapping a wrapper around said bunch, a slide arranged to move lengthwise of said wrapping-rollers, a wrapper-platform for feeding the wrapper to said rollers and pivoted to a fixed part, a connection between the slide and platform for imparting a swinging motion to the latter, a shoe carried by said slide, a shaft having a double spiral groove engaged by said shoe, a driven cam gear-wheel for intermittently rotating said shaft, brushes for brushing the wrapper tight around the bunch, an arm pivoted on said slide and carrying said brushes, said arm receiving an intermittent swinging motion from said cam gear-wheel, and a flat brush pivoted on said platform and controlled by means on said revolving brush-carrying arm, as set forth.

79. An automatic cigar-making machine having rollers for wrapping a wrapper around a bunch, a slide moving lengthwise of the rollers, an arm pivoted on said slide, revolving brushes journaled in said arm, a segmental gear-wheel on said arm, and racks having movement in the direction of the movement of the slide, and adapted to mesh with said segmental gear-wheel, as set forth.

80. An automatic cigar-making machine having rollers for wrapping a wrapper around a bunch, a slide moving lengthwise of the rollers, an arm pivoted on said slide, revolving brushes journaled in said arm, a segmental gear-wheel on said arm, racks having movement in the direction of the movement of the slide, and adapted to mesh with the said segmental gear-wheel, a shaft carrying said racks, and a cam-wheel for imparting a sliding motion to said shaft, as set forth.

81. An automatic cigar-making machine having rollers for wrapping a wrapper around a bunch, a slide moving lengthwise of the rollers, an arm pivoted on said slide, revolving brushes journaled in said arm, a segmental gear-wheel on said arm, racks having movement in the direction of the movement of the slide, and adapted to mesh with the said segmental gear-wheel, a shaft on which said racks are pivoted, springs pressing on the free ends of said racks, and a cam-wheel for imparting a sliding movement to said shaft, as set forth.

82. An automatic cigar-making machine having a plurality of wrapping-rollers forming a pocket for a bunch, and arranged to wrap a wrapper around said bunch, a fixed platform on one side of the rollers, a support on the other side of the rollers at or near one end thereof, to support the wrapper on both sides of the opening leading to the pocket, and a lug on said support to form an abutment for one edge of the wrapper, as set forth.

83. An automatic cigar-making machine having a plurality of wrapping-rollers forming a pocket for a bunch, and arranged to wrap a wrapper around said bunch, a fixed platform on one side of the rollers, a support on the other side of the rollers at or near one end thereof, to support the wrapper on both sides of the opening leading to the pocket, a lug on said support to form an abutment for one edge of the wrapper, and a finger adapted to engage the top of the wrapper between said support and said platform, directly over the pocket-opening, as set forth.

84. An automatic cigar-making machine having a plurality of retaining rollers forming a pocket, arms mounted to swing at one end of the pocket and transversely of the same, head-forming devices adjacent to the end of the pocket, and a yieldingly-mounted shield between the arms arms at the end of the pocket, as set forth.

85. An automatic cigar-making machine having a plurality of retaining rollers forming a pocket, arms mounted to swing at one end of the pocket and transversely of the same, head-forming devices adjacent to the end of the pocket, a yieldingly-mounted shield between the arms at the end of the pocket, and V-shaped knives secured on said arms, to cut the head end of the wrapper, said head-forming devices being inclosed by the knives, as set forth.

86. An automatic cigar-making machine having a plurality of retaining rollers forming a pocket, arms mounted to swing at one end of the pocket and transversely of the same, head-forming devices adjacent to the end of the pocket, a yieldingly-mounted shield between the arms at the end of the pocket, V-shaped knives secured on said arms, to cut the head end of the wrapper, said head-forming devices being inclosed by

the knives, concentric shafts carrying said knife-arms, and a driven cam-wheel having connection with said concentric shafts for rocking the shafts in opposite directions, as set forth.

87. An automatic cigar-making machine having a brush, and means for moving the brush into and out of the cigar-head-forming device for cleaning the same, as set forth.

88. An automatic cigar-making machine having a cigar-head-forming device, a brush for cleaning the cigar-head-forming device, and means for imparting an up-and-down and a transverse motion to said brush, as set forth.

89. An automatic cigar-making machine having a brush, a lever on which the handle of the brush is pivoted, means for imparting a swinging motion to said lever in a transverse direction, and means for imparting an up-and-down swinging motion to said brush, as set forth.

90. An automatic cigar-making machine having a brush, a lever on which the handle of the brush is pivoted, arms fulcrumed on said lever on opposite sides of its fulcrum, a link connecting the arms with each other, a second link connecting one of the arms with the handle of the brush, and a cam device for said arms, for imparting motion thereto and to said lever, as set forth.

91. An automatic cigar-making machine having a brush, a lever on which the handle of the brush is pivoted, arms fulcrumed on said lever on opposite sides of its fulcrum, a link connecting the arms with each other, a second link connecting one of the arms with the handle of the brush, and a cam device for said arms, for imparting motion thereto and to said lever, said cam device comprising a driven wheel, and cam-lugs on said wheel, and arranged to engage said arms, as set forth.

92. An automatic cigar-making machine having a plurality of rollers forming a pocket for receiving a bunch and for wrapping a wrapper around said bunch, a finger for carrying the butt-end of the wrapper to the butt-end of the bunch in said pocket, a ring on which said finger is secured, a sleeve on which the ring is pivoted, a revolvable shaft on which the sleeve is mounted to slide loosely, said shaft having means for engagement by the finger to turn the same around with the shaft, a shifter for the sleeve, a slide-shaft having a bearing for said shifter, a slide-rod for rocking the shifter in its bearing, and a cam gear-wheel for actuating the slide-shaft and said slide-rod, as set forth.

93. An automatic cigar-making machine having a plurality of rollers forming a pocket for receiving a bunch and for wrapping a wrapper around said bunch, a finger for carrying the butt-end of the wrapper to the butt-end of the bunch in said pocket, a ring on which said finger is secured, a sleeve on which the ring is pivoted, a revolvable shaft having means for engagement by the finger to turn the same around with the shaft, a shifter for the sleeve, a slide-shaft having a bearing for said shifter, a slide-rod for rocking the shifter in its bearing, a cam gear-wheel for actuating the slide-shaft and said slide-rod, and means for driving said revolvable shaft from said cam gear-wheel, as set forth.

94. In a cigar-machine, the combination of mechanism for forming a bunch, mechanism for wrapping a bunch, mechanism for transferring the bunch from the bunch-forming mechanism to the wrapping mechanism, and mechanism for causing the several operations to occur in proper sequence.

706,268. FORM FOR TACK-MACHINES. FRED A. SIBLE, Providence, R. I. Filed Nov. 6, 1901. Serial No. 81,269. (No model.)

Claim.—1. In a device of the character described, the combination with a stand, of a support arranged to hold a nipper, means for adjusting the support transversely to the nipper, and a guide arranged to support a strip carried by the nipper.

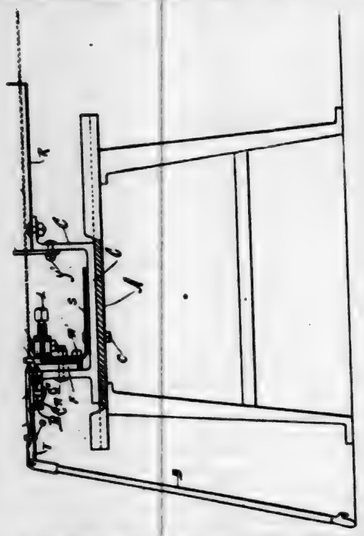
2. In a device of the character described, the combination with a stand, of a support arranged to hold a nipper, a guide arranged to support a strip carried by the nipper, and means for vertically adjusting the guide.

3. In a device of the character described, the combination with a stand, of a support arranged to hold a nipper, and a guide having a V-shaped slot arranged to support a strip carried by the nipper, by the walls of its V-shaped portion, and means for vertically adjusting the guide.

4. In a device of the character described, the combination with a stand, of a support arranged to hold a nipper, three guides arranged to support a strip carried by the nipper, and means for vertically adjusting the intermediate guide.

5. In a device of the character described, the combination with a stand, of a support arranged to hold a nipper, a plurality of guides arranged to support a strip carried by the nipper, one of said guides being located in proximity to the nipper, and having members adjustable transversely to the strip.

6. In a device of the character described, the combination with a stand, of a support arranged to hold a nipper, and a guide arranged to support a strip carried by the nipper, said guide comprising a pair of jaws pivotally supported from the stand, a spring arranged to move the jaws together, and a set-screw arranged to separate said jaws.



7. In a device of the character described, the combination of a stand, a support mounted on the stand and arranged to hold a nipper with the nipper-rod in a nearly vertical position with one end resting on the floor, means for adjusting the support to hold the nipper in a higher or lower position, and a plurality of guides arranged to support a strip carried by the nipper.

8. In a device of the character described, the combination of a stand, and a support mounted on the stand and arranged to hold the nipper with the nipper-rod in a nearly vertical position with one end resting on the floor, and three guides arranged to support a strip carried by the nipper, one of said guides being located in proximity to the nipper and having members adjustable transversely to the strip, and means for adjusting the intermediate guide vertically.

706,269. WEB-PRINTING PRESS. WILLIAM SPALCKHAVER, Brooklyn, N. Y., assignor, by direct and mesne assignments, to Robert Hoe and Charles W. Carpenter, New York, N. Y., under the firm-name of R. Hoe and Company. Filed Oct. 30, 1897. Serial No. 656,908. (No model.)

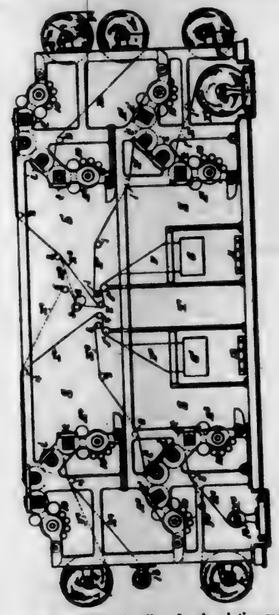
Claim.—1. The combination with a plurality of web-printing mechanisms arranged in the same vertical planes with their cylinders parallel, of two folding and delivery mechanisms having longitudinal folders arranged in line with said between said web-printing mechanisms with the folders facing in opposite directions and away from each other toward the opposite ends of the press, substantially as described.

2. The combination with a plurality of web-printing mechanisms arranged in the same vertical planes with their cylinders parallel, of two folding and delivery mechanisms arranged in line with and between said web-printing mechanisms with the front side of the folding and delivery mechanisms facing in opposite directions and away from each other toward the respective ends of the press, substantially as described.

3. The combination with a plurality of web-printing mechanisms arranged in the same vertical planes with their cylinders parallel, of folding and delivery mechanisms arranged in line with and between said web-printing mechanisms, and pairs of web-roll supports, as 13, 14, for each printing mechanism arranged at the opposite ends of the press and positioned for the lead to the respective printing mechanisms of a web from a roll mounted in either of the corresponding pair of supports and to permit the substitution of a full web-roll for an exhausted roll in either support of a pair while the printing mechanism is running on a web from a web-roll mounted in the other support of said pair, substantially as described.

4. The combination with a plurality of web-printing mechanisms arranged in the same vertical planes with their cylinders parallel, of two longitudinal folders arranged in line with said web-printing mechanisms with the folders facing in opposite directions and away from each other toward the opposite ends of the press, substantially as described.

5. The combination with a plurality of web-printing mechanisms arranged in the same vertical planes with their cylinders parallel, of two longitudinal folders arranged in line with said web-printing mechanisms with the folders facing in opposite directions and away from each other toward the opposite ends of the press, and means for directing the webs from the printing mechanisms to either of the longitudinal folders or partly to one longitudinal folder and partly to the other, substantially as described.



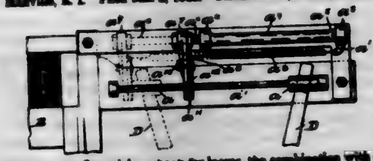
6. The combination with a plurality of web-printing mechanisms arranged in line with each other, with their cylinders parallel, of two folding and delivery mechanisms having longitudinal folders arranged in line with and between said web-printing mechanisms, with the folders arranged back to back and facing toward the opposite ends of the press.

7. The combination with a plurality of web-printing mechanisms arranged in line with each other, with their cylinders parallel, of two folding and delivery mechanisms arranged in line with and between said web-printing mechanisms, with the front side of the folding and delivery mechanisms facing in opposite directions and away from each other toward the respective ends of the press.

8. The combination with a plurality of web-printing mechanisms arranged in line with each other with their cylinders parallel, of two longitudinal folders arranged in line with said printing mechanisms, with the folders arranged back to back and facing toward the opposite ends of the press.

9. The combination with a plurality of web-printing mechanisms arranged in line with each other, with their cylinders parallel, of two longitudinal folders arranged in line with said web-printing mechanisms, with the folders arranged back to back and facing toward the opposite ends of the press, and means for directing the webs from the printing mechanisms to either of the longitudinal folders or partly to one longitudinal folder and partly to the other.

706,270. PICKER-CHECK FOR LOOMS. ADOLPH ST. ARNAUD, Manville, R. I. Filed Jan. 2, 1902. Serial No. 88,173. (No model.)



Claim.—1. In a picker-check for looms, the combination with a tube and a picker-rod sliding in the tube, of a bracket secured to the picker-rod and having its face provided with a cushion, a metal plate covering the face of the cushion, and the tensile spring secured to the bracket and a fixed part of the loom near the end of the shuttle-box, as described.

2. In a picker-check for looms, the combination with the shuttle-box, the picker, and the picker-rod, of the tube a^4 closed at one end, the opening a^5 near the closed end of the tube, and the brackets a^6 and a^7, of the picker-rod a^3, the bracket a^7 secured to the piston-rod, the cushion a^{11}, the plate a^{12} secured to the bracket by the bolt a^{13}, and the tensile spring a^8 secured to the bracket and a fixed part of the loom, as described.

706,271. MAIL-BAG FASTENER AND LOCK. ELMER STEVENS, Redfield, S. D. Filed June 12, 1901. Serial No. 64,366. (Model.)

Claim.—1. The combination with a bag, of a strap encircling the bag and having its ends extended, and a locking device comprising a sleeve slidably arranged on the ends of the strap, said strap being provided with registering holes j' to be engaged by the locking device when the strap is tightened on the bag to close the same, substantially as described.

2. The combination with a bag, of a strap encircling the bag and fastened thereto at or about its middle, said strap being provided with registering holes j' and having its ends extended and connected together, a locking device comprising a sleeve through which the ends of the strap slide and means for engaging the holes in the strap when the latter is drawn taut on the bag to close the same, substantially as described.

3. The combination with a bag of a strap encircling the bag and having its ends extended, a locking device slidably arranged on the ends of the strap, and a hook fastened to the bag and engaging and holding the locking device.

4. The combination with a strap, of a sleeve slidably arranged on said strap, a lock on one side of the sleeve, and a hasp pivoted to the sleeve on the other side thereof and provided with a post arranged to pass through holes in the sleeve and strap and enter the lock.

5. The combination with a strap, of a sleeve slidably arranged on said strap, a lock on one side of the sleeve, lugs on the other side of the sleeve, a hasp pivoted in said lugs and provided on its outer side with a card-holder, and a post on its other side to pass through openings in the sleeve and strap and enter the lock.

6. The combination with a bag, of a strap loosely encircling the bag and having its ends extended, said strap being fastened at or about its middle to the bag and having a stop at its ends, a locking device arranged on said strap between said stop and the bag and comprising an elongated sleeve through which the strap operates freely, and means for locking the strap and sleeve together, substantially as described.

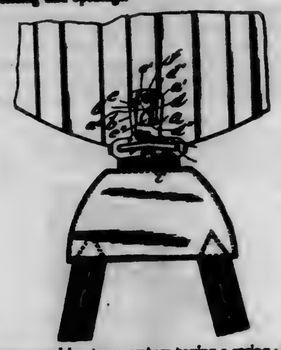
7. The combination with a bag, of a strap encircling the bag and attached thereto on one side and having its ends extended said strap being provided with registering holes in its sides, a sleeve slidably arranged on the ends of the strap and having a flared end adjacent to the bag, a lock carried by the sleeve on one side thereof, a hasp pivotally supported on the other side of the sleeve, and a post carried by the hasp and arranged to pass through openings in the sleeve and said openings in the strap when the strap has been drawn through the sleeve to close the bag.

8. The combination with a bag, of a strap encircling the bag, a locking device arranged on said strap and comprising a hasp, a post on the hasp arranged to enter openings in the strap and a lock for securing the hasp in engagement with the strap, substantially as described.

706,272. CLASP. CHARLES W. STURGIS, New York, N. Y. Filed Dec. 6, 1901. Serial No. 84,788. (No model.)

Claim.—1. A clasp comprising two members having a spring-hinge connection with each other, and having overlapping portions, in which are overlapping openings, adapted each to permit the passage of the head of a stud through it, and in conjunction with the other opening, to pro-

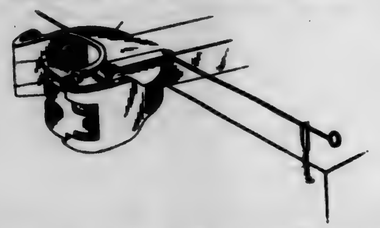
vent escape of said stud, when the parts are in normal position, the portions of said members which bound said openings being continuous and completely inclosing said openings.



2. A clasp comprising two members having a spring-hinge connection with each other, and having overlapping portions in which are overlapping openings, each such opening being bounded continuously and comprising a larger portion adapted to permit the passage of the head of a stud through it, and a narrower or contracted portion arranged at an angle to said larger portion.

3. A clasp comprising two members having a spring-hinged connection with each other, and having overlapping portions in which are overlapping openings, each such opening being bounded continuously and comprising a larger portion adapted to permit the passage of the head of a stud through it, and a narrower or contracted portion, the contracted portion of the opening of one member being narrower than that of the other.

706,273. CAR-COUPLING. WENDELL H. STILLWELL, Davenport, Iowa. Filed June 12, 1902. Serial No. 111,315. (No model.)



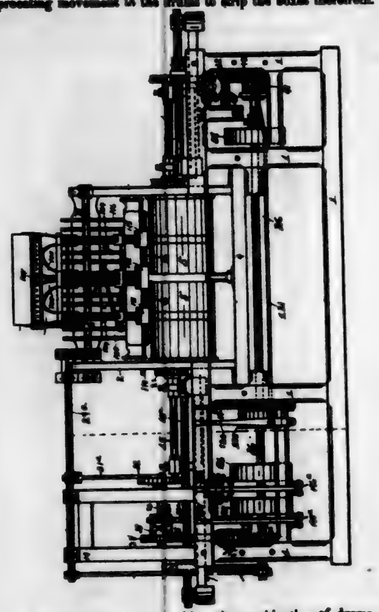
Claim.—1. The combination with a coupling of the Janney type comprising the head, the knuckle and the knuckle-pin for pivotally connecting the knuckle to the head, of an angular lever pivotally connected to the knuckle-pin and having one end connected to the knuckle, and means for operating the said lever, substantially as set forth.

2. The combination with a coupling of the Janney type comprising the head, the knuckle and the knuckle-pin for pivotally connecting the knuckle to the head, of an angular lever pivotally connected to the knuckle-pin and provided with an aperture alined with the coupling-pin aperture of the knuckle, and a coupling-pin inserted through said apertures of the knuckle and the aperture of the angular lever, and means for operating the angular lever, substantially as set forth.

706,274. MACHINE FOR MAKING VENEER BOXES. WILLIAM H. SHARP, Dayton, Ohio. Filed Feb. 7, 1902. Serial No. 93,041. (No model.)

Claim.—1. In a cylindrical-box machine, the combination of drums, means for imparting rotary movement to said drums during which the boxes are formed, mechanism for uniting the ends of the boxes and the hoops on the outer surface thereof, means for severing the cylinder from which the boxes are made, into suitable portions, and means for imparting longitudinally-reciprocating movements to said drums to strip the boxes therefrom.

2. In a cylindrical-box machine, the combination of drums, means for imparting rotary movement to said drums during which the material from which the boxes are constructed is carried around said drums, means for supporting the bottoms of the boxes in position to be received by the drums, uniting mechanism for uniting the material from which the boxes are formed, means for severing or cutting the cylinder into suitable parts to form the boxes, and means for subsequently imparting longitudinally-reciprocating movement to the drums to strip the boxes therefrom.



3. In a cylindrical-box machine, the combination of drums, means for imparting rotary movement to said drums during which the material from which the boxes are formed is carried around said drums, uniting mechanism for uniting the material from which the boxes are formed, further mechanism for applying metallic strips to the ends of the bands or hoops of said boxes, means for cutting the cylinder from which the boxes are formed into suitable portions, and means for imparting longitudinally-reciprocating movement to said drums at the completion of the formation of the boxes and during which said boxes are stripped from the drums.

4. In a cylindrical-box machine, the combination of drums, means for imparting intermittent rotary movement to said drums, during which the material from which the boxes are formed is carried around said drums, means for uniting said material during such intermittent rotary movement, means for imparting a subsequent continuous rotary movement to said drums during which the cylinder is formed from the material, cutting mechanism adapted to cut the cylinder in suitable portions to form boxes, means for uniting the metallic strips to the ends of the bands around said cylinder, and means for imparting horizontally-reciprocating movement to said drums at the completion of the formation of the boxes during which said boxes are stripped from the drums.

5. In a cylindrical-box machine, the combination of drums, means for imparting intermittent rotary movement to said drums, during which the material from which the boxes are formed is made into a cylinder, means for uniting said cylinder, and bands thereto, means for imparting a subsequent continuous rotary movement to said drums, means for cutting the cylinder in suitable portions during the last-named movement, means for supporting the bottoms of the boxes in position to be held by the drums during the formation of the cylinder, and mechanism for imparting horizontally-reciprocating movement to said drums after the boxes have been made and during which the boxes are stripped from the drums.

6. In a cylindrical-box machine, the combination of drums, means for imparting intermittent rotary movement to said drums, during which the cylinder from which the boxes are formed is completed, mechanism for uniting said cylinder during each movement, mechanism for uniting the ends of the bands or hoops around said cylinder by means of metallic strips, means for feeding such metallic strips into proper positions to be united to said bands, and cylinder, means for cutting the cylinder into suitable portions for boxes, means for supporting the bottoms of said boxes in positions to be received by the drums at the initial operation of said drums, and means for spreading or separating said drums at the completion of the boxes whereby said boxes are removed from said drums.

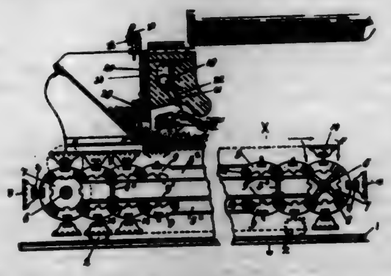
7. In a cylindrical-box machine, the combination of drums, means for imparting a rotary intermittent movement to said drums and a continuous rotary movement after the completion of said intermittent movement during which movements the material from which the boxes are made is formed in cylindrical shape around said drums, uniting mechanism for uniting the material in cylindrical form during the intermittent movement of the drums, and uniting mechanism for attaching metallic strips to the adjacent ends of the hoops or bands inclosing said cylinder, means for feeding said metallic strips into proper position to be united to said hoops or bands, and means for cutting the cylinder into suitable portions for boxes.

8. In a cylindrical-box machine, the combination of drums, means for imparting a rotary intermittent movement to said drums and a continuous rotary movement after the completion of said intermittent movement during which movements the material from which the boxes are made is formed in cylindrical shape around said drums, uniting mechanism for uniting the material in cylindrical form during the intermittent movement of the drums, uniting mechanism for attaching metallic strips to the adjacent ends of the hoops or bands inclosing said cylinder, means for feeding said metallic strips into proper position to be united to said hoops or bands, means for cutting the cylinder into suitable portions for boxes, and means for holding the bottoms of the boxes in position to be clamped by the drums in their initial movement.

9. In a cylindrical-box machine, the combination of drums, means for imparting an intermittent rotary movement and a continuous rotary movement after the completion of said intermittent movement during which movements the material from which the boxes are constructed is formed into cylindrical shape, uniting mechanism mounted on opposite sides of the machine, one set of such mechanism being adapted to unite the cylinder during the intermittent rotary movement of the drums, and the other set of said uniting mechanism being adapted to unite metallic strips to the ends of the bands or hoops inclosing said cylinder at the completion of said intermittent rotary movement, means for feeding said metallic strips into proper positions to be united to the bands, and means for severing the cylinder into suitable portions for boxes.

10. In a cylindrical-box machine, the combination of drums adapted to rotary and longitudinally-reciprocating movements, the former of such movements being adapted to form the material from which the boxes are made into cylindrical shape, and the latter of such movements being adapted to strip the boxes from said drums after their completion, means for holding the bottoms of the boxes in position to be held by the drums in their rotary movement, uniting mechanism adapted to unite the cylinder during the rotary movement thereof with the drums, means for feeding metallic strips into proper positions to unite the ends of the bands, uniting mechanism adapted to unite said metallic strips as they are fed in proper positions, and means for cutting said cylinders into proper parts for boxes after the operations of uniting said cylinder and the bottoms.

706,275. GRATE FOR BOILERS. HENRY SYLVESTER and FRED NOX SHEPHERD, Chicago, Ill. Filed Mar. 3, 1902. Serial No. 96,734. (No model.)



Claim.—1. In a combustion-chamber, the combination in a chain-grate stoker, of the grate-bars having locking-recesses 15' on their under sides the I-beam grate-carriers having upper flanges to engage said locking-recesses, the two-piece pivoted link-sections 9 hinged together at one side of the middle of said link, the longer section thereof having an inverted-T slot 13 to interlockingly engage the lower flanges of said I-beam grate-carrier and suitable upper and lower tracks and guideways for said links and rollers to support same in both their forward and rearward travel, substantially as described.

2. In a traveling grate, the combination of the individual grate-bars, each having the webbed upper surface and a base, said base having interlocking apertures or openings adapted to engage the flanges of the I-beam grate-carrier and hold said carrier against vertical movement, the I-beam grate-carrier having flanges engaging said interlocking apertures or openings 15', the pivoted two-section flexing links, each having in the upper side of one section thereof the inverted-T slots for engaging the opposite flanges of said I-beam grate-carriers to hold said carriers against movement in a vertical direction, and having on their under sides the lugs or teeth directly opposite to said T-shaped apertures, the chain-cams 7 for engaging said lugs, and the antifriction-rollers in the ends of said two-section links, substantially as described.

3. In a traveling grate, the combination with the coking-furnace and the grate-carriage of the flanged and apertured removable grate-sections, the grate-bar carriers 14 adapted to interlock with said grate-sections, the curved two-section links provided with the short forked ends adapted to receive the cheek of the adjoining link and containing the antifriction-rollers, said links being provided with the long cheek-section 9 and the short section provided with the inverted-T-shaped aperture 13 interlocking with the lower flanges of the grate-carrier 14, and also provided with the teeth or lug 9' engaging cams 7, and the I-beam rails and angle-plates upon which said rollers travel, substantially as described.

4. In a traveling grate, the combination of the grate-bars 15 having T-shaped openings 15' interlocking with the upper flanges of the grate-bar carriers, the grate-bar carriers having flanges on their upper sides engaging said openings and also having engaging flanges on their under sides, the antifriction-roller links having two sections hinged together, one thereof being larger than the other, said larger section having the T-shaped opening interlocking with the grate-carrier flanges, the cams 7 engaging the teeth 9' on the under side of said links, and the I-beam rails and angle-plates supporting said grate, substantially as described.

5. In a traveling grate the combination of the grate-bars having openings 15', the I-beam grate-carriers, having upper and lower flanges, the upper thereof being adapted for interlocking engagement with said openings 15', the arched, two-part hinged links having openings 13 on their upper sides adapted to engage said lower flanges, said links being provided with the lugs or teeth on their under sides, the rollers pivoted on the ends of said hinged links, and the I-beam rails between and on the upper and lower flanges of which said rollers travel, substantially as described.

6. The combination of the series of grates, movable over and around the movable framework, the individual roller-links 9 attached to said grates and moving therewith to support all of said grate-sections on an equal level, the I-beam and angle-plate guides 5', 5' for said rollers governing their movement in a vertical direction, the interlocking means 13, 14 and 15' provided in and between said grate-sections and links, and the means for moving said series of grates over and around said framework, substantially as described.

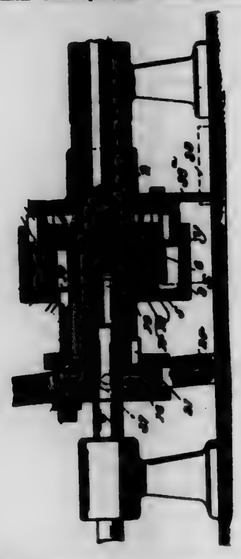
7. The combination of the series of grates, movable over and around the movable framework, the individual supporting-links 9 for each of said grate-sections and movable therewith to support the entire upper and lower surfaces of said grate on a level, the guiding-rails 5', 5' in said framework coacting with said supporting means, the interlocking apertures and flanges 13, 14 and 15' in said grate-sections, links and grate-carriers, the spider provided at the rear end of said chain-grate stoker to prevent the products of combustion from falling inside of same, and means for moving said grate and spider, substantially as described.

706,276. COMPRESSOR. JOHN STUMPF, Berlin, Germany. Filed May 8, 1901. Serial No. 59,514. (No model.)

Claim.—In a steam-actuated earbon-fluid compressor, the combination of a single cylinder forming both the steam-chamber and the compression-chamber, a piston working in the cylinder exposed on one side to the steam and performing on its other side the work of compression, a steam inlet and outlet slide-valve, means for positively moving the valve consisting of a stem connected at one end to the valve and provided at its other end with a shoulder, said stem being movable in a chamber in

the piston, a shoulder at the lower end of the chamber adapted in the upward movement of the piston to engage the shoulder on the stem to close the valve, a shoulder at the upper end of the chamber adapted in the downward movement of the piston to engage the end of the stem to open the valve, and piston-returning means opposing the force of the piston-moving means.

706,277. REVERSING FRICTION-CLUTCH. ARNOLD M. DYRENG, Marquette, Mich. Filed Sept. 4, 1901. Serial No. 74,373. (No model.)



Claim.—1. A reversing-gearing comprising, in combination, a driving-shaft, a driven shaft, a coupling-head on each shaft, one head having a true concentric surface and a tapered surface, the other head having an inner tapered surface opposite the tapered surface of the former head, an expansion-ring carried by one head for engaging the true concentric surface of the other head, means for acting on each ring to effect its engagement with the said concentric surface, a series of friction-rolls designed to be thrown into frictional engagement with the tapered surface of the two heads when the expansion-ring is out of engagement, and means for actuating said rolls, substantially as set forth.

2. A reversing-gearing comprising, in combination, a driving-shaft, a driven shaft, a coupling-head on each shaft, one head having an inner true concentric surface and an outer tapered surface, the other head having an inner tapered surface opposite the tapered surface of the former head, an expansion-ring carried by one head for engaging the true concentric surface of the other head, means for expanding said ring, a series of friction-rolls designed to be thrown into frictional engagement with the tapered surfaces of the two heads when the expansion-ring is out of engagement, and means for actuating said rolls, substantially as set forth.

3. A reversing-gearing comprising, in combination, a driving-shaft, a driven shaft, a coupling-head on each shaft, one head having an inner true concentric surface and an outer tapered surface, the other head having an inner tapered surface opposite the tapered surface of the former head, an expansion-ring carried by one of the heads for engaging the inner true concentric surface of the other head, means for expanding said ring, auxiliary means for positively coupling said heads supplemental or in addition to the coupling effected by the expansion-ring, a series of friction-rolls designed to be thrown into frictional engagement with the tapered surfaces of said heads when the friction-ring and auxiliary means are out of engagement, and means for actuating said rolls, substantially as set forth.

4. The combination with the driving-shaft, its coupling-head having an inner true concentric surface and an outer tapered surface, of the driven shaft, the coupling-head thereon having a central bore and an inner tapered surface opposite the before-mentioned tapered surface, a friction-ring fixed on said bore within the concentric surface of the coupling-head of the driving-shaft, a sliding collar carried by the coupling-head of the driven shaft, means actuated by said collar for expanding said ring, a lever for shifting said collar, a series of rolls between said tapered surfaces, a disk supporting said rolls, and connections between said disk and said lever, substantially as set forth.

5. The combination with the driving-shaft having a coupling-head with an inner true concentric surface and an outer tapered surface, of the driven shaft, the coupling-head thereon having a central bore and an inner tapered surface opposite the before-mentioned tapered surface, a friction-ring fixed on said bore within the concentric surface of the coupling-head of the driving-shaft, a sliding collar carried by the coupling-head of the driven shaft, a wedging-bar carried by said collar and designed to be forced between the ends of said ring, a lever for shifting said collar, a series of rolls between said tapered surfaces, a disk supporting said rolls, and connections between said disk and said lever, substantially as set forth.

6. The combination with the driving-shaft having a coupling-head with an inner true concentric surface, and an outer tapered surface, of the driven shaft, the coupling-head thereon having a central bore and an inner tapered surface opposite the before-mentioned tapered surface, a friction-ring fixed on said bore within the concentric surface of the coupling-head, of the driving-shaft, a sliding collar carried by the coupling-head of the driven shaft, a wedging-bar carried by said collar and designed to be forced between the ends of said ring, said bar being split longitudinally and having a central bore, a regulating-pin extended through said bore and having a tapered head for engaging the bar at its end, means for adjusting said pin, a lever for shifting said collar, a series of rolls between said tapered surfaces, a disk supporting said rolls, and connections between said disk and said lever, substantially as set forth.

7. The combination with the driving-shaft and its coupling-head having an inner true concentric surface and formed with openings in its wall, of the driven shaft, the coupling-head thereon having a central bore, reversing-gearing between said heads, an expansion-ring on said bore, a sliding collar, spring-pressed pins carried by said collar and extended through openings in the coupling-head of the driven shaft for entering said openings of the other coupling-head, and means for actuating said collar, substantially as set forth.

8. The combination with the driving-shaft and its coupling-head having an inner true concentric surface, of the driven shaft, the coupling-head thereon having a central bore formed with a groove, reversing-gearing between said heads, a split ring on said bore having a lug fitted in said groove, a wedging-bar for expanding said ring, a sliding collar carrying said wedging-bar, a lever for actuating the collar, two spring-pressed pins mounted on the collar and extended through the head of the driven shaft and designed to extend into the openings in the coupling-head of the driving-shaft.

9. The combination with the driving-shaft and its coupling-head having a central bore, of the driven shaft, the coupling-head thereon having a central bore, reversing-gearing between said heads, a coupling-pin fitted in said bore and extended into the bore of the driving-shaft coupling-head, a locking-pin engaging said coupling-pin, a split ring on said bore, a cap-plate holding said ring and coupling-pin, a wedging-bar for expanding the ring, a sliding collar, and means for actuating the same, substantially as set forth.

10. The combination with the driving-shaft, and its coupling-head, of the driven shaft, the coupling-head thereon, means for effecting a positive engagement between said heads for causing both shafts to rotate in the same direction, a lever for controlling such means, a series of friction-rolls between said heads for reversing the rotation of the driven shaft, a disk on which such rolls are mounted, connections between such disk and lever, a plate extending from such disk, and a stop with which such plate is designed to engage when the rolls are in action, substantially as set forth.

11. The combination with a coupling-head and a shaft, said head having an inner true concentric surface and an outer tapered surface, of a second coupling-head having a tapered surface and an expansible friction-ring for engaging said inner concentric surface, a wedge for expanding said ring, shiftable means for moving said wedge into and out of engagement with said ring, a series of tapered rolls for engaging both concentric surfaces, a disk supporting such rolls, a connection between such disk and shiftable means, and a plate having a bore through which the shaft is passed, both coupling-heads being concentric with the shaft, which latter is limited in its longitudinal movement in coupling and uncoupling, substantially as set forth.

706,278. FOLDER FOR SEWING-MACHINES. WILBUR L. SWIFT and EDWARD BURR, New York, N. Y., assignors to The Union Special Sewing Machine Company, Chicago, Ill., a Corporation of Illinois. Filed Mar. 6, 1901. Serial No. 49,725. (No model.)

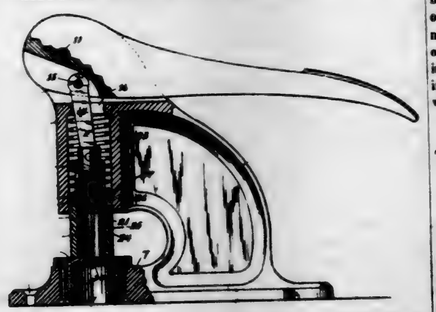
Claim.—1. The herein-described folding-guide for ruffling and sewing machines, comprising a folding and guiding-recess, a guiding-lip and a guiding-recess opposed to the first folding and guiding recess, whereby the raw edge of a plaited fabric may be folded and guided, the plait guided by the lip, and the edge of the fabric to be ruffled guided in the recess substantially as described.

2. The herein-described folding-guide for sewing-machines, comprising a lower folding and guiding recess, a vertically-extending guiding-lip, and a guiding-recess above said folding and guiding recess and opposed thereto, whereby the raw edge of a plaited fabric may be folded and guided, the plait guided by the lip and the edge of the other fabric guided in the recess; substantially as described.

3. The herein-described folding-guide for ruffling and sewing machines, comprising a folding and guiding recess, a guiding-lip and a guiding-recess opposed to the first folding and guiding recess, and a forwardly-projecting spring-tongue whereby the raw edge of a plaited fabric may be folded and guided, the plait guided by the lip, and the edge of the fabric to be ruffled guided in the recess; substantially as described.

4. The herein-described folding-guide for ruffling and sewing machines, comprising a folding and guiding recess, a guiding-lip and a guiding-recess opposed to the first folding and guiding recess, whereby the raw edge of a plaited fabric may be folded and guided, the plait guided by the lip, and the edge of the fabric to be ruffled guided in the recess, and a trough-shaped recess arranged in advance of the folding-guide; substantially as described.

706,279. PUNCH. HENRY S. TEMPLE, Milwaukee, Wis. Filed Dec. 20, 1901. Serial No. 86,662. (No model.)



Claim.—1. The combination of a base having a standard projecting therefrom, and a chambered arm extending from the standard, a lever pivoted to the standard, a tubular spring-pressed plunger movable in the chamber of the arm, the spring-pressure being exerted in a direction to force the plunger outwardly from the chamber, a punch-carrier fitting movably in the bore of the plunger, a connection between the carrier and the lever, whereby when the lever is operated the carrier is moved either toward or from the material to be punched, in accordance with the direction of the turning of the lever, a supporting medium for the material to be punched, said supporting medium located beyond, and in line with, the chambered arm, and provided with an opening therethrough for the passage of the punch, means for causing the plunger and carrier to move outwardly together for a certain distance, and for causing the carrier and its punch to move outwardly after the plunger comes in contact with the material to be punched, to thereby force the punch through said material, means for holding the plunger in contact with the punched material during the withdrawal of the punch, and means, after the withdrawal of the punch, for causing the carrier and plunger to move together away from said punched material.

2. The combination of a base having a standard projecting therefrom, and a chambered arm extending from the standard, a lever pivoted to the standard, a spring-pressed tubular plunger movable in the chamber of the arm, the spring-pressure being exerted in a direction to force the plunger outwardly from the chamber, and said plunger provided longitudinally with a key-seat, one end of said key-seat leading to a slot extending through the plunger into the bore thereof, a key fitting said seat and bearing against the wall of the chambered arm, said key having one end provided with a lug projecting through the slot and into the bore of the plunger, a punch-carrier fitting movably in the bore of the plunger and provided with a shoulder adapted, at certain periods of the movement, to make contact with the lug of the key, a connection between the carrier and the lever, whereby when the lever is operated the carrier is moved toward or from the material to be punched, in accordance with the direction of turning of the lever, and a supporting medium for the material to be punched, said medium provided with an opening through which the punch is adapted to pass.

3. The combination of a base having a standard projecting therefrom, and a chambered arm extending from the standard, a lever pivoted to the standard, a spring-pressed tubular plunger movable in the chamber of the arm, the spring-pressure being exerted in a direction to force the plunger outwardly from the chamber, and said plunger provided within its bore with a shoulder, and also provided longitudinally with a key-seat, one end of said key-seat leading to a slot extending through the plunger into the bore thereof, a key fitting said seat and bearing against the wall of the chambered arm, said key having one end provided with a lug projecting through the slot and into the bore of the plunger, a punch-carrier fitting movably in the bore of the plunger and provided with a shoulder adapted, at certain periods of the movement, to make contact with the lug of the key and also with the interior shoulder of the plunger, a connection between the carrier and the lever, whereby when the lever is operated the carrier is moved toward or from the material to be punched, in accordance with the direction of turning of the lever, and a supporting medium for the material to be punched, said supporting medium provided with an opening through which the punch is adapted to pass.

4. The combination of a base having a standard projecting therefrom, and a chambered arm extending from the standard, a lever pivoted to the standard, a spring-pressed tubular plunger movable in the chamber of the arm, the spring-pressure being exerted in a direction to force the plunger outwardly from the chamber, a wedge-key adapted to be wedged in between the plunger and the inner wall of the chambered arm, when the plunger engages the material to be punched, a punch-carrier fitting movably in the bore of the plunger and adapted, at certain periods of the movement, to release said key from wedging engagement, a connection between the carrier and the lever, whereby when the lever is operated the carrier is moved toward or from the material to be punched, in accordance with the direction of turning of the lever, and a supporting medium for the material to be punched, said supporting medium provided with an opening through which the punch is adapted to pass.

706,280. PREPARING SURFACES FOR ETCHING AND IN ETCHING SUCH SURFACES. FRANCIS H. TRIBODO and SEBASTIAN S. PECKHAM, Greenbay, Wis.; said Peckhamagh assignor to Rutherford B. H. Macrorie, Greenbay, Wis. Filed June 13, 1899. Serial No. 720,345. (No specimens.)

Claim.—1. In the art of etching glass, or similar substances, the process which consists in covering one surface of a sheet of glass with a coating composed of albumen, water, ammonia, chrome-alum and bichromate of ammonia in the proportions specified; in then drying this coating in subdued light; in passing actinic rays through the glass into the coating; in then developing sensitized and exposed carbon tissue on this coating; in then subjecting the sheet of glass to the action of hydrofluoric gas, eroding the surface of the glass; and in then removing the remaining portion of the coating.

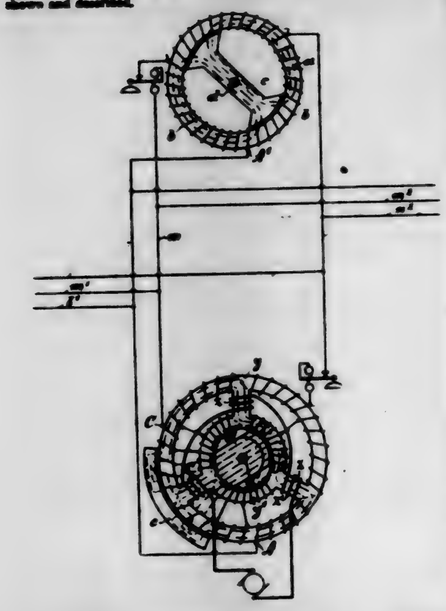
2. In the art of etching glass, or similar substances, the process which consists in covering one surface of a sheet of glass with a coating composed of albumen, water, ammonia, chrome-alum and bichromate of ammonia in the proportions specified; in then drying this coating in subdued light; in then exposing this coating to the light; in then developing sensitized and exposed carbon tissue on this coating; in then eroding the surface of the plate on which the coating is placed to a depth varying with the protection afforded by the coating; and in then removing the remaining portion of the coating.

706,281. MEANS FOR TRANSMITTING MOVEMENTS AND INDICATING POSITIONS ELECTRICALLY. WILHELM A. THIERBACH, Hanover, Germany. Original application filed Nov. 12, 1901, Serial No. 82,022. Divided and this application filed Apr. 4, 1902. Serial No. 101,288. (No model.)

Claim.—1. In a system for the transmission of movements and positions of indicators by means of electric currents, the combination of one apparatus, consisting of a bipolar rotor without windings and a stator having a primary winding, which is connected to a source of electricity, and also a secondary winding, with one or more apparatuses, consisting of a bipolar rotor without windings and a stator having only one winding, whose sections are respectively connected to the sections of said secondary winding at the corresponding points, substantially as shown and described.

2. In a system for the transmission of movements and positions of indicators by means of electric currents, the combination of one apparatus, consisting of a bipolar rotor without windings and a stator having a primary winding, which is connected to a source of electricity, and also a

secondary winding, with one or more apparatuses, consisting of a bipolar rotor without windings and a stator having only one winding, whose extremities are respectively connected to the ecstions of said secondary winding at the corresponding points, by lines, one of which near to each apparatus is provided with a bell, which sounds only when compensating currents enter and which stops ringing, when the rotor is adjusted, substantially as shown and described.



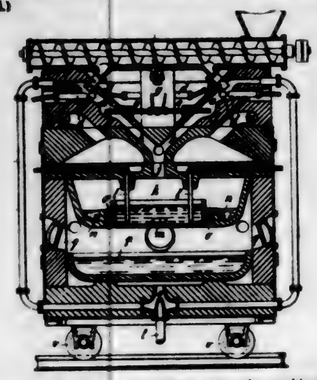
706,282. PAPER-FEEDING MACHINE FOR TYPE-WRITERS. HARRY C. TOBEY, Salina, Kans. Filed July 12, 1901. Serial No. 67,266. (No model.)

Claim.—1. In a device of the character described, the combination of a supporting-frame having triangular side pieces, the crown-bars of which are vertically disposed at the front of the frame, paper-rolls journaled in said crown-bars, a carbon-roll journaled in the rear central angles of the side pieces, means for winding up the carbon-paper on the carbon-roll, and braking devices for said paper-rolls consisting of tension-springs bearing on the rolls and mounted upon the arms of one of the said triangular side pieces, substantially as described.

2. In a device of the character described, the combination of a supporting-frame having triangular side pieces formed with open bearings in their crown-bars and at their central angles, said crown-bars being disposed vertically at the front of the frame, paper-rolls journaled in the open bearings in the crown-bars, a carbon-roll journaled in the open bearings at the said central angles, means for rotating the carbon-roll to wind up the carbon-paper thereon, and braking devices for said paper-rolls consisting of tension-springs bearing on the rolls and mounted upon the arms of one of the said triangular side pieces, substantially as and for the purpose specified.

3. In a device of the character described, the combination of a supporting-frame having triangular side pieces formed with open bearings in their crown-bars and at their central angles, said crown-bars being disposed vertically at the front of the frame, paper-rolls journaled in the open bearings in the crown-bars, a carbon-roll journaled in the open bearings at the said central angles, tension-springs adjustably secured to the arms of one of the triangular side pieces and serving as braking devices bearing on the paper-rolls, a pinion mounted upon the axis of the carbon-roll, and a crank-operated gear-wheel meshing with said pinion to adapt the carbon-roll to be rotated to wind up the carbon-paper thereon, substantially as set forth.

706,283. ELECTRIC GLASS-FURNACE. ADOLF VOELKER, Cologne, Germany, assignor to Company l'Industrie Verrière et ses Dérivés, Brussels, Belgium. Filed Apr. 26, 1901. Serial No. 57,489. (No model.)



Claim.—1. In a furnace for melting glass, the combination with a plurality of inclined passages converging to form a common outlet, an inlet for each of said passages, electrodes to form an arc immediately at the inlet to each of said passages, electrodes positioned in the respective passages below the first-named electrodes, a refining-pot located immediately below the common outlet of the said passages and electrodes positioned in said pot.

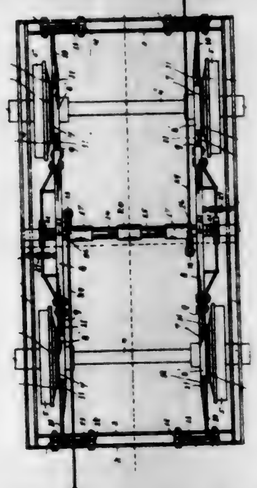
2. In a furnace for melting glass, the combination with a plurality of inclined passages converging to form a common outlet, electrodes in said passages, an inlet for each of said passages, a refining-pot below said outlet and a basin below the refining-pot, of outlets forming a continuation of the respective passages above the said inlets for the escape of combustible gases produced in said passages and pipes leading from said outlets to a suitable burner below the basin whereby said basin is heated by said gases.

706,284. CAR-BRAKE MECHANISM. AUGUST W. VOLLSTORF, Toledo, Ohio. Filed Nov. 26, 1901. Serial No. 84,070. (No model.)

Claim.—1. In a car-brake, the combination with a truck-frame mounted on wheels having friction-disks on their inner webs concentric to their axles, of a pair of bars movably supported in parallel position between the wheels by the truck-frame, and having shoes secured thereto opposite each wheel-disk, concentrically to their axle; an extension-rod coupling the parallel bars, comprising a central and end sections, the center section being like threaded at both ends; and the inner ends of the end sections being reversely threaded to the adjacent ends of the middle section, and having their outer ends adapted to be coupled to the parallel bars; sleeves internally threaded for coupling the sections, each sleeve having a radial arm; means to couple the radial arms each to an operating-lever at opposite ends of the car; and means to prevent rotation of the middle and end sections of the extension-rod.

2. In a car-brake, the combination with a truck-frame mounted on wheels having friction-disks on their inner webs, concentric to their axles, of a pair of bars movably supported in parallel position between the wheels by the ends of the truck-frame, and having shoes secured thereto opposite each wheel-disk, concentrically to their axle; an extension-rod coupling the parallel bars, comprising a central and end sections, the center section being like threaded at both ends, and the inner ends of the end sections being reversely threaded to the adjacent ends of the middle section, and having their outer ends reduced in diameter and threaded; sleeves internally threaded for coupling the sections, each sleeve having a radial arm; orifices central to the bars adapted to receive the reduced ends of the middle sections; nuts for the threaded ends of the end sections adapted to secure the extension-rod thus formed to the bars; means to prevent rotation of the middle and end sections; a lever pivoted to each platform of the car and a link-rod connecting each lever with the arm of one of the sleeves.

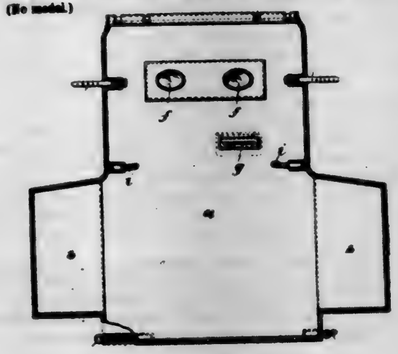
3. In a car-brake, the combination with a truck-frame mounted on wheels having friction-disks on their inner webs, concentric to their axles, of a pair of transed bars movably supported in parallel position between the wheels by stirrups pivoted to the ends of the truck-frame, and having shoes secured thereto opposite each wheel-disk, concentrically to their axle; an extension-rod coupling the parallel bars, comprising a central and end sections, the center section being like threaded at both ends, and the inner ends of the end sections being reversely threaded to the adjacent ends of the middle section, and having their outer ends adapted to be coupled to the parallel bars; sleeves internally threaded for coupling the sections, each sleeve having a radial arm; means to couple the radial arms each to an operating-lever at opposite ends of the car respectively; and stay-chains connecting the parallel bars to the sides of the truck-frame adapted to adjustably limit the retraction of the bars.



4. In a car-brake mechanism, the combination with a shoe-supporting bar, having an arch for spanning the axle of a car-truck and provided with pendantly-pivoted arms curved to complete the circle of the arch when their free ends are abutted, of an annular brake-shoe disk inset to admit the axle central thereto, and having hooks at the back adapted to engage the arms and arch and be held thereby when the arms are abutted and locked together.

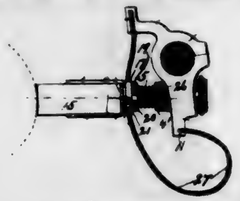
5. In a car-brake, the combination with a truck-frame mounted on wheels having friction-disks on their inner webs, concentric to their axles, of a pair of bars movably supported in parallel position between the wheels by stirrups pivoted to the ends of the truck-frame, and having shoes secured thereto opposite each wheel-disk, concentrically to their axle; and means to laterally advance and retract the bars.

706,285. COMBINED STORM-APRON AND DUST-HOOD. GUSTAVE WALTER, Sandwich, Ill. Filed Feb. 5, 1902. Serial No. 92,841. (No model.)



Claim.—A combined storm-apron and dust-hood consisting of a waterproof flexible fabric provided at its lower end with means for attaching it to the dashboard and at its side edges with means for detachably fastening it to the top-props and at its upper end with means for attaching it to a buggy-top, this latter means consisting of a flexible strip attached to the upper edge of the apron and adapted to flex transversely to fit buggy-tops of various shapes and sizes, means being provided on the buggy-top for detachably clamping said strip under the front edge of the buggy-top.

706,286. BRUSH-HOLDER. FRANK T. WELDAW, Syracuse, N. Y. Filed Feb. 10, 1902. Serial No. 93,441. (No model.)



Claim.—1. A brush-holder comprising a support, a laminated bow-spring having opposite ends secured to the support and its central portion movable toward and away from said support, and a brush-clamp secured to the central portion of the spring.

2. A brush-holder comprising a support, a spring having its opposite ends secured to the support and its intermediate portion movable toward and away from the support, and a brush-clamp secured to the intermediate portion of the spring.

3. A brush-holder comprising a support having a guideway, a reciprocally-movable brush-clamp guided in said way, and a spring fixed to the support at opposite sides of the guideway and its intermediate portion movable and provided with a clamp to hold the brush to the commutator.

4. A brush-holder comprising a support, a reciprocally-movable brush-clamp guided on the support, a spring having its opposite ends secured to the support at opposite sides of the clamp and its intermediate portion fixed to the clamp to hold the brush to the commutator.

5. In a brush-holder, a support, a movable brush-clamp provided with a stem guided on the support and a spring secured to the support at opposite sides of the stem and its intermediate portion movable and provided with a clamp to hold the spring to the commutator.

6. In a brush-holder, a support having an adjustable member provided with a guideway, a reciprocally-movable brush-clamp guided in said way and a spring operating between the adjustable member and clamp and insulated therefrom for moving the brush-clamp away from the support toward the commutator.

7. A brush-holder comprising a support having an adjustable member provided with a guideway, a brush-clamp guided in said way and insulated from said member, and a spring interposed between the member and brush-clamp for forcing the brush to the commutator.

8. A brush-holder comprising a support, a brush-clamp having a projecting rod, a sleeve formed of insulating material guided in the support and encircling a rod, and a spring operating upon the clamp to force the brush to the commutator.

9. A brush-holder comprising a support having a threaded aperture, a threaded sleeve movable in the aperture, a plunger-rod movable in the sleeve and insulated therefrom, a brush-clamp secured to the rod and a spring interposed between the sleeve and clamp and operating to force the brush to the commutator.

10. A brush-holder comprising a support, a reciprocally-movable brush-clamp guided in the support, a bow-spring having its ends fixed to the support and its central portion movable toward and away from said support and provided with a clamp to hold the brush to the commutator, and yielding means for holding the central portion of the spring away from the support.

11. A brush-holder comprising a support, a threaded member adjustable on the support and provided with a guideway, a sleeve of insulating material guided in said way and having one end provided with an annular shoulder, a spring interposed between the adjustable member and said annular shoulder, a brush-clamp actuated by the sleeve to force the brush to the commutator and having a stem extending into the sleeve.

12. A brush-holder comprising an arm, a support adjustable on said arm and provided with a threaded aperture, an adjustable threaded sleeve in the aperture, a brush-clamp having one of its jaws adjustable toward and away from the other, a rod or stem secured to the clamp and projecting into the threaded sleeve, an insulating-sleeve surrounding said rod

or stem, a spring interposed between the adjustable sleeve and clamp for holding the brush to the commutator and an additional spring having its opposite ends secured to the support and its intermediate portion secured to the clamp.

13. In a brush-holder, a support, a laminated spring having its opposite ends secured to the support, a reciprocally-movable brush-clamp guided on the support and secured to the intermediate portion of the spring, said clamp having oppositely-arranged jaws, one of which is adjustable toward and away from the other.

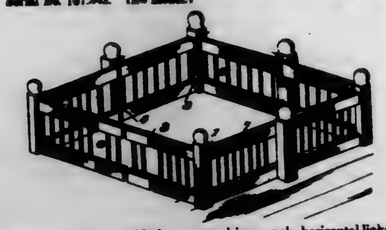
706,287. **SHADE-BRACKET.** FREDERICK YARR, Paterson, N. J. Filed Feb. 3, 1902. Serial No. 92,573. (No model.)

Claim.—1. The combination of a shade-roller bracket consisting of a plate having one end portion thereof formed as spaced parallel guides and with a tongue between said guides, and having its other end portion turned off at right angles to said guides and constituting the roller-carrying portion of said bracket, said tongue having a rebend or hump serving as a knob, and a guiding-support for said bracket, said support having teeth adapted to be engaged by the tongue and grooves adapted to receive said guides, substantially as described.

2. The combination of a shade-roller bracket consisting of a plate having one end portion thereof formed as spaced parallel guides and with a tongue between said guides, and having its other end portion turned off at right angles to said guides and constituting the roller-carrying portion of said bracket, said tongue having a rebend or hump serving as a knob, and a guiding-support for said bracket, said support having teeth adapted to be engaged by the tongue and grooves adapted to receive said guides and the tongue, substantially as described.

3. The combination of a shade-roller bracket consisting of a plate having one end portion thereof formed as spaced parallel guides and with a tongue between said guides, and having its other end portion turned off at right angles to said guides and constituting the roller-carrying portion of the bracket, and a guiding-support for said bracket, said support having grooves adapted to receive said guides, and another groove intermediate said first-named grooves and adapted to receive said tongue, and said support also having teeth in the intermediate groove adapted to be engaged by said tongue, substantially as described.

706,288. **PORTABLE TOY FENCE.** CHRISTIAN J. YOUSE, Jr., JOHN R. YOUSE, and LOUIS A. YOUSE, Baltimore, Md. Filed May 14, 1902. Serial No. 107,342. (No model.)



Claim.—1. A portable fence comprising panels, horizontal links pivotally connecting the panels, a post, and hooks projecting from the post, said hooks engaging the links, the ends of the panels being seated against the post and held against lateral displacement by the hooks engaging the links, substantially as described.

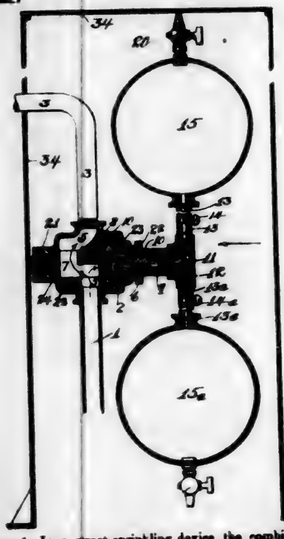
2. A portable fence comprising panels, horizontal links pivotally connecting the panels, an opening being formed in the links, a post, and hooks projecting from the post, said hooks engaging the openings in the links, the ends of the panels being seated against the post and held against lateral displacement by the hooks engaging the openings in the links, substantially as described.

3. A portable fence, comprising two panels disposed at an angle to each other, links pivotally connected to the panels, a post having faces corresponding to the ends of the panels, the ends of said panels fitting said faces of the post, and hooks projecting from the post, said hooks engaging the links to bind the panels to the post to prevent lateral displacement of the panels, substantially as described.

4. A portable fence comprising a plurality of panels, horizontal links pivotally connecting the panels together, an intermediate post or posts, square faces being provided on the posts, hooks projecting from said post to engage the links of two panels disposed in line with each other, end posts interposed between and at the angle formed between the two end panels, said post being squared off to form faces, hooks projecting from the end posts to engage the links connecting the end panels, the ends of the panels fitting squarely the faces of the posts to prevent lateral displacement of the said panels, substantially as described.

5. In a portable fence, the combination with two or more panels normally resting on a base or support, of horizontal links pivotally connecting the panels together, posts interposed between each two adjacent panels, said posts normally resting on the same base or support as the panels, and fastening devices permanently fixed to the posts for engaging the links to bind the panels and posts together, substantially as described.

706,289. **AUTOMATIC STREET-SPRINKLING DEVICE.** TERRY D. YOUNG, Memphis, Tenn. Filed Sept. 9, 1901. Serial No. 74,849. (No model.)



Claim.—1. In a street-sprinkling device, the combination with a supply-pipe and an automatic regulating-valve for same consisting each of a vertical pipe, a sleeve on said pipe having its upper surface beveled in the form of a flat inverted cone, a flat inverted cone fitting the bevel top of said sleeve, and adjustable to and from it to regulate the flow of water, and a flat band surrounding the head below the opening thus formed and having a part extended above and closing the said opening, substantially as and for the purposes described.

2. In a street-sprinkling device, the combination with a supply-pipe and an automatic regulating-valve for same, of sprinkling-heads consisting each of a vertical pipe, a sleeve on said pipe having its upper surface beveled in the form of a flat inverted cone, a hub in said sleeve, a screw extending upward from said hub and an inverted flat cone fitting the bevel top of said sleeve and adjustable toward and from it along said screw, and a flat band surrounding the head below the opening thus formed and having a portion extended above and closing part of the said opening, substantially as and for the purposes set forth.

3. In an automatic street-sprinkling device, the combination with a sprinkling-head and a water-supply pipe of means of regulating the flow of water to said sprinkling-head, consisting of a valve, a valve-stem extending beyond the said valve suitable stuffing-boxes for said valve-stem, water-channels through said valve-stem, which are alternately open to the water in said valve, a T on the end of said valve-stem, pipes leading oppositely from said T, water-reservoirs on said pipes substantially as and for the purposes set forth.

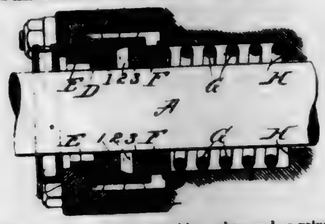
4. In an automatic street-sprinkling device, the combination with a sprinkling-head and a water-supply pipe of means of regulating the flow of water to said sprinkling-head consisting of a valve, a valve-stem extending beyond the said valve, suitable stuffing-boxes for said valve-stem, water-channels through said water-stem, which are alternately open to the water in said valve, a T on the end of said valve-stem, pipes leading oppositely from said T, a ball-valve in said T adapted to rest on the lower pipe and close the passage through same and water-reservoirs on said pipes, substantially as and for the purposes set forth.

5. In an automatic street-sprinkling device, the combination with a sprinkling-head and a water-supply pipe of means of regulating the flow of water to said sprinkling-head, consisting of a valve, a valve-stem extending beyond the said valve suitable stuffing-boxes for said valve-stem, water-channels through said valve-stem, which are alternately open to the water in said valve, a T on the end of said valve-stem, pipes leading oppositely from said T, a ball-valve in said T adapted to rest on the lower pipe and close the passage through same, means of regulating the flow of water through said pipes, and water-reservoirs on said pipes, substantially as and for the purposes set forth.

6. In an automatic street-sprinkling device, the combination with a sprinkling-head and a water-supply pipe of means of regulating the flow of water to said sprinkling-head, consisting of a valve, a valve-stem extending beyond the said valve suitable stuffing-boxes for said valve-stem, water-channels through said valve-stem, which are alternately open to the water in said valve, a T on the end of said valve-stem, pipes leading oppositely from said T, a ball-valve in said T adapted to rest on the lower pipe and close the passage through same, means of regulating the flow of water through said pipes, an overbalance-chamber on the sides of each of said water-reservoirs and means of filling said overbalance-chamber after the water-reservoir has filled, substantially as and for the purposes described.

7. In an automatic street-sprinkling device, the combination with a sprinkling-head and a water-supply pipe of means of regulating the flow of water to said sprinkling-head, consisting of a valve, a valve-stem extending beyond the said valve suitable stuffing-boxes for said valve-stem, water-channels through said valve-stem, which are alternately open to the water in said valve, a T on the end of said valve-stem, pipes leading oppositely from said T, a ball-valve in said T adapted to rest on the lower pipe and close the passage through same, means of regulating the flow of water through said pipes, an overbalance-chamber on sides of each of said water-reservoirs, a pipe leading from the bottom of same to near the top of the overbalance-chamber, and suitable drains for each, substantially as and for the purposes set forth.

706,290. **METALLIC PACKING.** ALBERT J. SWART, Chicago, Ill. Filed Mar. 5, 1901. Serial No. 49,873. (No model.)



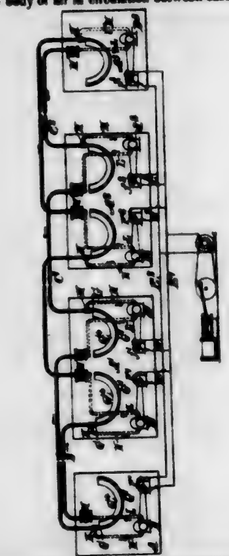
Claim.—1. The combination with a piston-rod or valve-stem and packing-case therefor, of a single vibrating cup containing a plurality of conical bores and one final cylindrical bore, wearing-rings within said bores, the combined length of said rings being less than the combined length of said bores, and a follower snugly fitting between said rod and the interior circumference of said cylindrical bore and longitudinally movable therein; substantially as described.

2. The combination with a piston-rod or valve-stem and packing-case therefor, a vibrating cup, and a wearing-ring in said cup, of a follower fitting about said rod and in said cup and bearing snugly and directly between said rod and the interior circumference of said cup, whereby said follower connects said rod and cup and causes them to move together during the vibration of said rod; substantially as described.

3. The combination with a rod having an enlarged diameter at its extremity and a packing-case therefor, of a vibrating cup having a split bushing, said vibrating cup being bored to provide two or more centrally-bounded, and one cylindrically-bounded conical cavities around the rod, metallic wearing-rings, a combination sliding face and ball-seated ring, a follower, a spring, and a stuffing-box bushing against which said follower bears; substantially as described.

706,291. **SYSTEM AND APPARATUS FOR TRANSMITTING CARRIERS IN PNEUMATIC-DISPATCH TUBES.** BERNEY C. BATCHELLER, Philadelphia, Pa. Filed Nov. 3, 1900. Serial No. 736,092. (No model.)

Claim.—1. A pneumatic transmission system comprising three or more stations, each connected to the adjacent station by an outgoing and incoming transmission-tube, said tubes having their receiving ends in each station connected to the delivery-conduit of an air-compressor situated at or near each station and their delivery ends in each station open to the atmosphere, an air-conduit in each station leading from a point in the transmission-tubes near their open delivery ends to the suction-conduits to the air-compressors aforesaid, all substantially as described, and so as to maintain one body of air in circulation between each two adjacent stations.



2. A pneumatic transmission system comprising a series of stations, outgoing and incoming transmission-tubes connecting said stations in pairs, air-compressors situated in separate stations of the series connected to force air into the receiving ends of the tubes and draw air from them at points adjacent to their delivery ends, electric motors in the separate stations connected to drive the compressors, an electric generator common to the system and circuit connections leading therefrom to the motors aforesaid.

3. In a pneumatic transmission system comprising three or more stations connected in pairs by outgoing and incoming transmission-tubes, said tubes being connected at their receiving ends to sources of air under pressure and open to the atmosphere at their delivery ends, and air-pumps having their suction-conduits connected to the delivery ends of the transmission-tubes a short distance from their open ends, the combination with a transmitter situated in the receiving end of a transmission-tube at one station of a curved delivery-table, as G^7 G^8, connected with the delivery end of a transmission-tube leading to the station and a chute as G^9, leading from said table to the transmitter.

706,292. **PIPE-HANGER.** ALLAN J. BEATON, Southington, Conn. Filed Oct. 16, 1900. Serial No. 33,290. (No model.)

Claim.—1. In a pipe-hanger, the combination of the buckle-frame having a rectangular opening, with the locking-bar formed of plate metal bent into the form of an inverted V with notches at each end in the junction of the two legs to receive the side bars of the frame, and the flexible metal strap fastened by one end to the said bar and with its other end free to pass between the said locking-bar and the lower end of the frame, substantially as described.

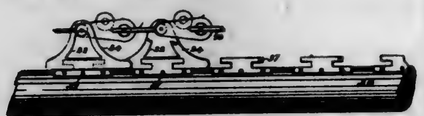
2. In a pipe-hanger, the combination of the rectangular buckle-frame with the locking-bar in the form of an inverted V fitted to slide vertically within the said frame, and the long flexible metal strap having one end rolled over the top of the said V-shaped bar and around the lower end of one leg thereof and secured thereto by having the extreme end forced up in between the two legs of the bar near their junction, substantially as described.

3. In a pipe-hanger, the combination of a buckle-frame with the roll 12, on the lower end bar of the frame and a V-shaped locking-bar mounted to slide within the said frame, and having the lower ends of its legs spread apart for exerting a pressure upon the roll at the laterally opposite sides of the lower end bar of the said frame, substantially as described.

4. In a pipe-hanger, the combination of the buckle-frame with a locking-bar having two depending legs, the said bar being loosely mounted within the said frame at the apex of the said bar, whereby the said bar may rock laterally on its fulcrum according to the varying pressure on the lower end of the legs, substantially as described.

5. The combination of a buckle-frame having side bars and a lower end bar, with a two-legged locking-bar mounted within the said frame for sliding longitudinally to the said bar, and a sheet-metal hanger-strap doubled upon itself over one of the said legs and depending from the other one of the said legs, substantially as described.

706,293. PNEUMATIC TREAD OR TIRE. FRANK L. BRADSHAW, Sutton-Coldfield, England. Filed Oct. 11, 1901. Renewed July 9, 1902. Serial No. 114,981. (No model.)



Claim.—1. In a device of the class described, the combination with a plurality of metallic securing members consisting of flat base or bottom plates having upwardly-extending securing portions secured together at the top forming a link chain, of a hollow tubular endless tread provided with means for removably securing such tread to the face or bottom plates of pieces, substantially as shown and described.

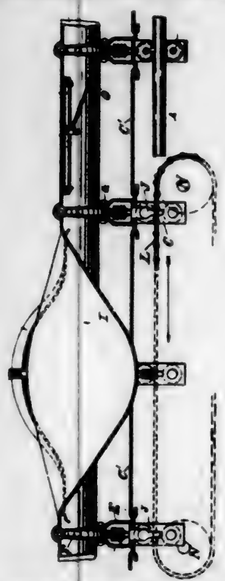
2. In a device of the class described, the combination with a plurality of securing members each consisting of a base or bottom plate provided with central orifices having end shoulders located at the side of the center of the end portions of said orifice, of a tubular tread or tire provided with metallic securing-lugs secured thereto in pairs the top members of which lugs are adapted to pass through the central portion of the hollow base or bottom plates and to be forced over upon the shoulders thereof upon the inflation of the tubular tread or tire so as to lock such tire to the base or bottom plates of the securing members so long as the same remains inflated, substantially as shown and described.

3. In a device of the class described, the combination with a plurality of securing members each consisting of a base or bottom plate provided with a rectangular central orifice provided at the end with a central entrance-slot, of link members securing such securing members together at the top in such manner that there will be a pivot-joint at the top of each of such securing members, a pivot-joint member secured between each pair of such members, an antifriction-roller carried by one of each pair of the link members so connecting the securing members, and a pair of T-shaped metallic securing-lugs for each pair of securing members secured to a tubular endless tread or tire, the construction being such that the securing-lugs may be passed through the central slotted portion of the abutting securing members one by one end upon inflation of the tire will be forced over the end shoulders thereof so as to lock such securing members to the tubular endless tread or tire so long as the same is inflated.

706,294. CONVEYER. FRITZ BENZ, New York, N. Y. Filed Apr. 13, 1901. Serial No. 55,626. (No model.)

Claim.—1. In a conveyer the combination of a rail, yokes traveling on same, connections between said yokes, means supported by said yokes for receiving the material to be carried, and means for operating the conveyer, substantially as described.

2. In a conveyer the combination of a rail, yokes traveling on same, connections between said yokes, means supported by said yokes for receiving the material to be carried, means for operating the conveyer and automatic means for discharging the load at any predetermined points.



3. In a conveyer the combination of a rail, yokes traveling on said rail, connections between said yokes, curved brackets supported by said yokes and a belt or apron supported by said brackets, substantially as described.

4. In a conveyer the combination of a rail, yokes traveling on said rail, connections between said yokes, curved tilting brackets supported by said yokes, a belt or apron supported by said yokes and means for tilting said brackets at any predetermined points, substantially as described.

5. In a conveyer the combination of a rail, yokes traveling on said rail, connections between said yokes, curved brackets supported by said yokes, a belt or apron supported by said brackets, and means for supporting the edge of the belt or apron when passing around curves, substantially as described.

6. In a conveyer the combination of a rail, yokes traveling on same, wheels on said yokes bearing one at the top and the other at the bottom of the rail, connections between said yokes, means supported by said yokes for receiving the material to be carried, and means for operating the conveyer, substantially as described.

706,295. STARTING MECHANISM FOR TRAINS. JOHN B. RLOOD, Newburyport, Mass. Filed Aug. 28, 1901. Serial No. 73,547. (No model.)

Claim.—1. A starting system for a train of cars, comprising pressure-controlling devices situated throughout the train, and means whereby the starting impulse is consequent upon the coincident condition of all of said pressure devices, as and for the purpose set forth.

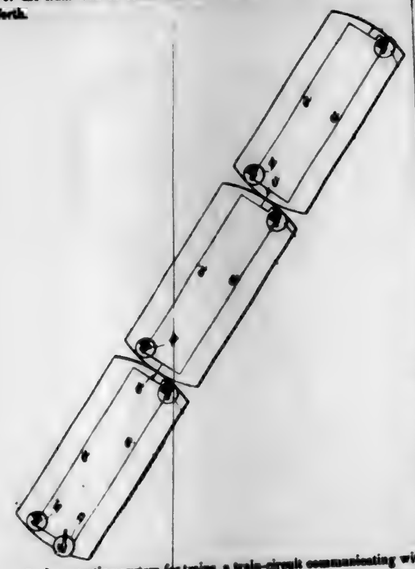
2. A starting system for trains including pressure-controlling devices mounted upon each car, a motor or other propelling device, said motor being controlled in its starting movements by coincident conditions of the pressure-controlling devices on all the cars, as and for the purpose set forth.

3. A starting system for trains, comprising a controller, a train-circuit, means for supplying pressure thereto, said means provided with devices throughout the train for controlling such pressure, as and for the purpose set forth.

4. In a starting system for trains, a controller arranged to control the supply of pressure to the motors, and pressure-control devices arranged on each car of the train in series with each other, as and for the purpose set forth.

5. In a starting system for trains, a train-circuit, switches arranged upon each car and in series with said train-circuit, a controller, said circuit supplying pressure to said controller, as and for the purpose set forth.

6. In a starting system for trains, a circuit arranged to extend throughout the train and communicating with a source of pressure, a controller to which such pressure is connected, and switches arranged on the various cars of the train and in series with said circuit, as and for the purpose set forth.



7. In a starting system for trains, a train-circuit communicating with a source of pressure, a controller arranged in said train-circuit, and normally open switches arranged in series with each other in said circuit and placed upon the various cars of the train, as and for the purpose set forth.

8. In a starting system for trains, a motor, a controller for controlling the supply of pressure thereto, a train-circuit for said controller for initially controlling the supply of pressure to said translating devices, and a normally open switch arranged at each end of each car of the train, said switches being included in series with each other in said open circuit, as and for the purpose set forth.

706,296. METAL CAN. JAMES H. BRADLEY, Washington, D. C. Filed Dec. 14, 1901. Serial No. 86,068. (No model.)

Claim.—1. A can having a partition immovably secured therein adjacent to its upper end, said partition being dished or concave-convex and provided with an opening the concaved side being arranged uppermost.

2. A can having a partition arranged therein adjacent to the upper end, said partition having a central opening and formed with means for securing it immovably in the can.

3. A can having a partition immovably secured therein adjacent to its upper end, said partition being dished or concave-convex and having an opening at its center the concaved face being arranged uppermost, and provided with means at its outer edge for connection to a can.

4. A can having a partition immovably arranged therein adjacent to its upper end, said partition having a central circular opening, said partition also having an annular flange by means of which it is connected to the can, substantially as described.

5. A can having a partition arranged therein adjacent to its upper end, said partition having a central circular opening, the partition also having an annular flange, the flange and can being corrugated or crimped for the purpose of securing the partition within the can.

706,297. APPARATUS FOR COMPARING HANDWRITINGS OR OTHER OBJECTS. JACQUES DE BRUN. (MARTHOD GERARDS BOSE.) Lausanne, Switzerland. Filed Feb. 12, 1902. Serial No. 93,731. (No model.)

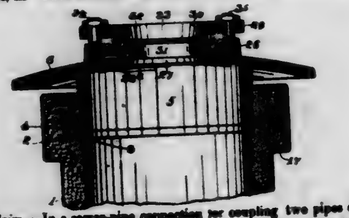
Claim.—1. In an instrument for comparing handwritings and other objects, the combination with a base and a frame, of a mirror secured in said frame, a mirror, in part reflecting and in part transparent, also secured in said frame, means in connection with said base for holding one of the objects to be compared, means for adjusting the position of the aforesaid means in the base, and means for reflecting the compared objects upon a screen, substantially as set forth.

2. In an instrument for comparing handwritings and other objects, the combination with the base *b* and frame *d*, of a mirror *c* secured in said frame, a mirror c' in part reflecting and in part transparent, also secured in said frame and parallel to the aforesaid mirror and at a slightly-higher elevation, the platform *f* for holding one of the objects to be compared, and wedges g^3 placed between the said base and platform *f* for adjusting the height of the platform *f* and object thereon in relation to the bottom of the base under which the second object is placed, substantially as specified.

3. In an instrument for comparing handwritings and other objects, the combination with the base *b* and frame *d*, of a mirror *c* secured in said frame, a mirror c', in part reflecting and in part transparent, also secured in said frame and parallel to the aforesaid mirror and at a slightly-higher elevation, a platform *f* for holding one of the objects to be compared, wedges g^3 between the said base and platform *f* for adjusting the height of the platform *f* and object thereon in relation to the bottom of the base under which the second object is placed, and a detachable mirror *i* to be placed in the upper part of said frame for reflecting the comparison of the objects upon a screen, substantially as specified.

4. In an instrument for comparing handwritings and other objects, the combination with a suitable framework-support, of an adjustable platform in a plane parallel to the surface carrying the support, a mirror carried by the support above the platform and a device in part reflecting and in part transparent set in a plane parallel to the mirror and carried by the support at a slightly-higher elevation than the mirror, substantially as and for the purposes set forth.

706,298. SEWER-PIPE CONNECTION. FRANK W. CARLSON, Chicago, Ill. Filed Mar. 21, 1902. Serial No. 99,333. (No model.)



Claim.—In a sewer-pipe connection for coupling two pipes of different diameters, the combination of the main connection adapted to enter the end of the larger pipe, the said main connection having a flange at its lower part, a ring of packing arranged between the said flange and the interior of the larger pipe, and L-bolts engaging the outside of the larger pipe and the main connection whereby the said packing may be pressed against the interior of the larger pipe, the said main connection having a downwardly-inclined overhanging portion projecting circularly over the open end of the larger pipe and adapted to protect the end from falling dirt or moisture, the said main connection having a central opening and an upwardly-extended central portion constituting the base of a stuffing-box, the complemental element 29 of the stuffing-box, a ring of

packing within the box and bolts connecting the said element 29 and the upwardly-extended central portion of the main connection whereby the packing within the stuffing-box may be forced against a pipe of relatively smaller diameter passing through it, substantially as described.

706,299. HAY-STACKER. THOMAS CASCADEN, Jr., Waterloo, Iowa, assignor to Cascaden Manufacturing Company, Waterloo, Iowa, a Corporation. Filed May 29, 1902. Serial No. 109,420. (No model.)

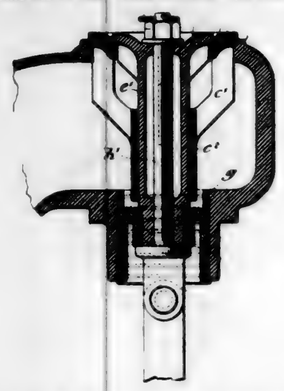
Claim.—1. A hay-stacker comprising the combination with the base-bars or runners, of a vertical frame at the rear of said base-bars or runners, swinging arms pivoted to the top of said vertical frame and provided at their forward ends with a fork or carrier, a mast pivoted between said arms, connections uniting the upper end of said mast to said fork or carrier, a pulley at the base of said vertical frame, pulleys at the top of said vertical frame and said mast and a lifting rope or cable passing around said pulleys.

2. A hay-stacker comprising the combination with the base-bars or runners, of a vertical frame at the rear of said base-bars or runners, said frame consisting of posts extending upwardly from each of said base-bars or runners and connected together at their tops, swinging arms pivoted at their rear ends to the top of said vertical frame and provided at their forward ends with a fork or carrier, a mast pivoted between said swinging arms and in front of said vertical frame, said mast being arranged to swing rearwardly between the forward posts of said vertical frame, connections between the top of said mast and said fork or carrier, pulleys located at the top of said mast and of said vertical frame and a lifting-rope extending between said pulleys and leading to the base of said vertical frame.

3. A hay-stacker comprising the combination with a base, of a vertical frame at the rear of said base, said vertical frame being provided with forwardly and downwardly extending brace-bars connecting the vertical frame with the base, swinging arms pivoted at their rear ends to the top of said vertical frame and provided at their forward ends with a fork or carrier, a mast pivoted between said swinging arms, connections between the top of said mast and said fork or carrier and a lifting rope or cable and pulleys located upon the top of said mast and said vertical frame.

4. A hay-stacker comprising the combination with the base-bars or runners, of a vertical frame at the rear of said base-bars or runners, said frame consisting of posts extending upwardly from each of said base-bars or runners and connected together at their tops, forwardly and downwardly extending brace-bars connecting the rear upper portion of said vertical frame with the central portion of said base-bars or runners, a mast having its lower end pivoted adjacent the central portion of said base-bars or runners, swinging arms having their rear ends pivotally connected to the top of said vertical frame and having their forward ends provided with a fork or carrier, connections between the top of said mast and said fork or carrier, pulleys at the top of said mast and said vertical frame, a pulley at the base of said vertical frame and a lifting rope or cable extending around said pulleys.

706,300. THROTTLE-VALVE. JOHN S. CHAMBERS, Wilmington, N. C. Filed Jan. 20, 1902. Serial No. 90,547. (No model.)



Claim.—1. A throttle-valve comprising a casing extending into a steam-space, valve-sections, means for balancing the valve-sections and a valve-operating rod arranged to operate the valve-sections, the passage-way for steam between both the valve-sections and their seats being over the top of the casing.

2. A throttle-valve comprising a valve-casing extending into a steam-space and provided with a valve-seat at its top, a valve-section fitted to said seat, a second valve-section seated within the aforesaid valve-section, means for balancing the valve-sections and a valve-operating rod for operating the sections, substantially as set forth.

3. A throttle-valve comprising a valve-casing extending into a steam-space and provided with a valve-seat at its top, a valve-section fitted to said seat, a second valve-section seated on said first-named valve-section and having a limited movement relative to the first-named valve-section, means for balancing said second valve-section and a valve-operating rod for operating the sections, substantially as set forth.

4. A throttle-valve comprising a casing having a valve-seat at its top, a valve-section fitted to said seat, a piston having a sliding movement in an opening at the bottom of said casing, a second valve-section connected with said piston and seated within the first-named valve-section and a valve-operating rod for operating the sections, substantially as set forth.

5. A throttle-valve comprising a suitable casing having a valve-seat at its top, a valve-section fitted to said seat, a piston having a sliding movement in an opening at the bottom of the casing, a valve-section seated within the aforesaid valve-section and connected with the piston and means for operating the piston, the said piston and the valve carried thereby having a movement relative to the other valve-section whereby the interior valve-section may be opened before the exterior valve-section is opened, substantially as set forth.

6. A throttle-valve comprising a casing extending into a steam-space and having a valve-seat, an annular valve-section fitted to the seat and provided with a depending sleeve connected with the annular valve-section by arms, an interior valve-section seated within the annular valve-section and having a limited movement with respect to the annular valve-section, means for balancing the interior valve-section and a rod for operating the two sections, substantially as set forth.

7. A valve box or casing provided with one valve-seat only, the said valve-seat being located at its top, and with a piston-receiving cylinder located at its bottom, in combination with a valve and piston fitted to said seat and cylinder, respectively.

8. The combination with a valve box or casing, of two valves located at the top of the box or casing, a rod for operating the valves at intervals with respect to each other and means connected with the valve-operating rod for balancing one of the valves, the opening of said balanced valve serving to admit fluid-pressure to balance the other valve.

706,301. BOTTLE-STOPPER. JOHN B. CROSBY, Buffalo, N. Y. Filed Nov. 27, 1901. Serial No. 83,873. (No model.)

Claim.—1. The combination with a bottle having a neck and oppositely-disposed depressions in its neck, of an angular bail having inwardly-bent ends adapted to be sprung into the depressions in the bottle-neck, a bottle-stopper having a semispherical top portion provided with a transverse opening, a washer on said stopper, a bifurcated locking-block pivotally connected to the bail and having the inner surface of its bifurcations curved to conform to the rounded form of the semispherical top portion of the bottle-stopper and a pivoting-pintle passing through the bottle-stopper and the bifurcations of the locking-block, substantially as set forth.

2. The combination with a bottle having a neck, of a stopper movably secured to said neck and provided with a flange and a semispherical top portion, a bail pivoted to the bottle-neck, a substantially U-shaped bifurcated block pivoted to the top portion of the stopper and the bail and having the lower ends of its bifurcations provided with fairly-wide bottom surfaces which seat on the flange, substantially as set forth.

3. The combination with a bottle having a neck, of a bail movably secured to said neck, a stopper having a flange and a semispherical top portion and a bifurcated locking-block having pivotal support from the bail with its bifurcations straddling and pivotally attached to the semispherical top portion of the stopper, the inner surface of the bifurcation being curved to conform to the semispherical form of the top portion, substantially as set forth.

4. The combination with a bottle having a neck, of an angular bail movably secured to said neck, a stopper having a flange and a semispherical top portion and a locking-block pivoted to the bail above the stopper and having downward extensions passing on opposite sides of and pivoted to the stopper and provided with an inner surface conforming to the semispherical top portion and a flat broad bottom surface adapted to seat upon the flange to retain the block in its vertical locking position, substantially as set forth.

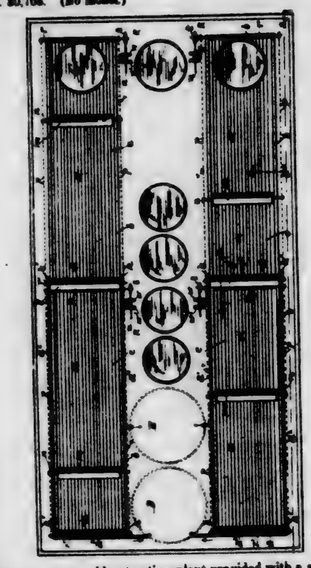
5. In combination, a bottle having a neck, a bail pivoted to the neck, a stopper having a semispherical top portion provided with a transverse opening, a bifurcated locking-block having an upper opening through which the bail passes and lower openings in the bifurcations, said bifurcations being adapted to extend on opposite sides of the top portion of the stopper and having curved inner surfaces conforming to the rounded form of the stopper, and a pivoting-pintle passed through the lower openings in the bifurcations and the opening in the top portion of the stopper, substantially as set forth.

6. In combination, a bottle having a neck, a bail pivoted to the neck, a stopper having a top portion provided with an opening below the top portion, a bifurcated locking-block having an upper opening through which the bail passes and lower openings in the bifurcations, said bifurcations being adapted to extend on opposite sides of the top portion of the stopper; and a pivoting-pintle passed through the lower openings in the bifurcations and the opening in the top portion of the stopper, substantially as set forth.

7. In combination, a bottle having a neck, a bail having pivotal connection with said neck, a stopper having a lower portion adapted to fit in the opening in the bottle-neck, a semispherical upper portion adapted to project above the bottle and an annular projecting flange intermediate the lower and upper portion and adapted to rest upon the top edge of the neck, and a U-shaped bifurcated locking-block having pivotal connection with the bail and stopper; said locking-block being adapted to have its bifurcations straddle and curve around the upper portion of the stopper and rest upon the flange when in locking position, substantially as set forth.

8. In combination, a bottle having a neck provided with oppositely-disposed depressions, an angular bail having inwardly-bent ends adapted to be sprung into the depressions, a stopper having a top portion provided with a rounded head, a lower portion having a tapering upper part merging in an enlarged button and a flange intermediate the top and lower portion, a washer adapted to be sprung over the button and onto the tapering portion, a locking block substantially in the form of an inverted U having an upper opening through which the bail passes and lower openings, and a pivoting-pintle passed through the lower openings in the block and the top portion of the stopper, substantially as set forth.

706,302. MEANS FOR EXTRACTING PRECIOUS METALS FROM ORES. LEVI B. DARLING, Providence, R. I. Filed Nov. 1, 1901. Serial No. 80,768. (No model.)



Claim.—1. In a gold-extracting plant provided with a substantially flat treating-floor *a*, of non-absorbent material, a series of longitudinally-extending channels *c* formed therein, a transverse groove or end launder *d* in direct communication with said channels, fixed screens or strainers covering the top of said channels and launder, side launders or ducts, and valved connections interposed between and uniting the said end and side launders, substantially as described.

2. In a gold-extracting plant, the combination with the treating-floor *a* having screen-covered grooves *c* and end launder *d*, of a mechanically-actuated rolling device adapted to be continuously propelled forth and back longitudinally of the floor, substantially as hereinbefore described and for the purpose set forth.

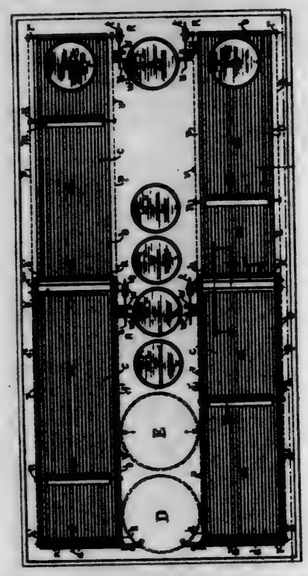
3. In a gold-extracting plant, the combination of the grooved treating-floor *a*, adapted to receive thereon a comparatively thin layer of finely-divided ore and treating solution constituting the pulp, a mechanically-actuated rolling device arranged to be continuously propelled forth and back to agitate the said pulp or material lying on the floor, suitable launders or ducts communicating with the grooved portion of the floor, and scamp-tanks into which the metal-charged solution is discharged from the launders, substantially as described.

4. In a gold-extracting plant, two laterally-separated double floors *a*, *a*, provided with suitable grooves and launders, rolling or agitating mechanism adapted to be propelled forth and back longitudinally of the floors scamp-tanks into which the metal-carrying solution is discharged, and suitably-arranged water, leach and solution tanks, substantially as described.

706,303. PROCESS OF EXTRACTING PRECIOUS METALS FROM ORES. LEVI B. DARLING, Providence, R. I. Filed Feb. 12, 1902. Serial No. 93,705. (No specimens.)

Claim.—1. The process or method hereinbefore described of extracting precious metals from finely-divided materials or ores, which consists in spreading a comparatively thin layer of the material over a substantially flat and large working surface provided with drainage ducts or channels; then covering said material with suitable metal-dissolving or cyanid

solution; then passing a heavy roll back and forth over the charge of material, &c., thereby at the same time thoroughly agitating or stirring the charge and forcing some of the solution into the drainage-ducts; then discharging said solution into the sump, and finally precipitating the precious metal from the solution.



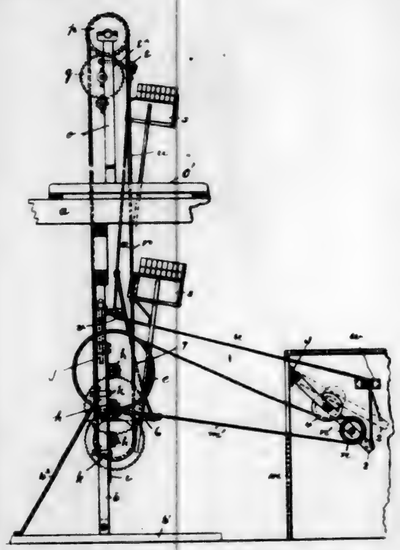
2. The improvement in processes of extracting precious metals from finely-divided ores, which consists in spreading a comparatively thin layer of the suitably-prepared ore treated with metal-dissolving solution over a substantially flat and broad floor; then rolling a weight back and forth over the material lying upon said floor, thereby at the same time thoroughly agitating and aerating the material and forcing out some of the metal-carrying solution, and finally treating the latter to extract or precipitate the precious metal therefrom.

706,804. HOOK AND EYE. CHARLES R. DEVINE, Toledo, Ohio, assignor of one-fourth to P. H. Goodall, Indianapolis, Ind. Filed Oct. 14, 1901. Renewed June 27, 1902. Serial No. 113,366. (No model.)

Claim.—As a new article of manufacture, a hook and eye consisting of a hook made of a single piece of wire, eyelets formed in each end of the wire, a head formed by the loop of the wire, said head being raised above the side wires, the connection between the head and the side wires forming shoulders, an eye composed of a single piece of wire, an eyelet D formed in one end of the wire, an eye B formed by the loop of the wire, a throat C formed by bending the wire inward behind the eye, a loop E formed opposite the eyelet B by bending the other end of the wire back upon itself so as to form a tongue K, said tongue extending through the throat C part way into the eye B, substantially as and for the purpose specified.

706,805. BED ELEVATOR OR HOIST. FRANK C. DEY, Newark, N. J. Filed Sept. 14, 1901. Serial No. 75,420. (No model.)

Claim.—1. In a bed hoist or elevator, the combination of a rigid rectangular support or framework *b*, adapted to be stationed in upright position at the bottom of the hoist, means for holding said support in fixed position, a shorter rigid rectangular frame *i*, comprising a single integral casting arranged flatwise against one side of said support and adapted to slide vertically thereon, means connecting said frame to said support and preventing lateral shifting thereon or outward movement therefrom while permitting endwise adjustment, a single adjusting-screw passing loosely through the middle of the top piece of said support and working in a threaded socket in the corresponding end piece of the frame, transverse shafts journaled near their opposite ends upon the opposite upright lateral portions of said frame and lying approximately in the plane of the frame, and a conveyer-belt pulley, driving-pulley and connecting-gears mounted on said shafts.



2. In a bed hoist or elevator having upper and lower bearings, an endless conveyer-belt passing around said bearings, a continuously-operating source of power, means normally transmitting power from said source of power to the conveyer-belt, and controlling means adapted to be engaged by a load on the conveyer and disengage said transmitting means to stop the conveyer or belt without stopping the source of power.

3. In a bed-hoist, a conveyer-belt, a sprocket-wheel and driving-pulley at one end of said belt, a suitable source of power and a belt adapted to transmit motion to the driving-pulley, means normally tightening said belt, and a lever *l*, adapted to be engaged by a load on the conveyer-belt and being connected to said power-belt-tightening means.

4. In a bed hoist having a conveyer-belt and sprocket-pulleys therefor, a loose power-belt connected to the bottom sprocket, a lever *l*, adapted to be engaged by a load on the conveyer-belt, a lever having a friction-pulley for tightening the power-belt and a connecting-rope extending from said lever *l*, to the belt-tightening lever.

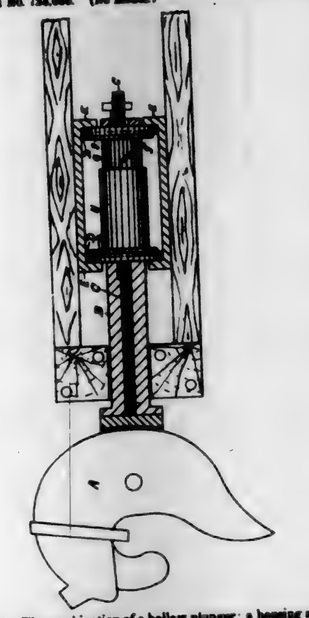
5. In a bed-hoist having a lower sprocket-wheel and driving-pulley, an upper sprocket, and a conveyer-chain, a loose power-belt passing around said driving-pulley, tightening means therefor, a brake for said pulley, a lever *l*, adapted to be engaged by a load on the conveyer, and means connecting said lever to the said brake and power-belt-tightening means.

6. In a bed hoist or elevator, a conveyer-belt, a pulley geared to said belt, a continuously-rotating driving-pulley, a loose belt passed over said pulleys, a pressure-roller normally tightening said belt to transmit power, a lever adapted to be engaged by a load on the conveyer, and connecting means extending from said lever to the said pressure-roll and adapted to release the latter from the belt when the lever is operated.

7. In a bed hoist or elevator, a conveyer-belt, a pulley geared to said conveyer-belt and having a braking-surface, a brake, a continuously-rotating driving-pulley, means for connecting and disconnecting said pulley and driving-pulley, a lever adapted to be engaged by a load on the conveyer-belt, and means connecting said lever to said brake and to said connecting and disconnecting means whereby the latter are operated conjointly to stop or start the conveyer-belt irrespective of the driving-pulley.

8. In a bed-hoist the combination with the conveyer-belt, supporting means therefor, and driving means, of a lever *l*, connected to the driving means and adapted to be operated by a load on the conveyer to disengage the driving means, said lever being fulcrumed on the outer end of a crank-shaped pin l^2, adapted to be turned in its seat to adjust the position of the lever.

706,806. MEANS FOR AUTOMATICALLY REGULATING THE RESISTANCE OF RESILIENT DEVICES. PHILO C. HUART, Cincinnati, Ohio, assignor of one-half to Charles A. Barnard, Cincinnati, Ohio; Myra V. Huart, executrix of said Philo C. Huart, deceased. Filed Aug. 23, 1899. Serial No. 728,086. (No model.)



Claim.—1. The combination of a hollow plunger; a housing adapted to receive the plunger; a coiled spring within the plunger having one end adapted to engage the plunger and the other adapted to engage the housing, and screw-threads on the plunger and housing whereby the spring may be wound as it is compressed, substantially as and for the purpose set forth.

2. The combination of a hollow plunger; a housing adapted to receive the plunger; friction-heads upon the plunger and housing; a coiled spring within the plunger having one end adapted to engage with and be rotated by the friction-head on the plunger and the other end adapted to engage with and be rotated by the friction-head on the housing; and screw-threads on the plunger and housing whereby the spring may be wound as it is compressed, substantially as and for the purpose set forth.

3. The combination of a coiled spring mounted in bearings, one or both of which are rotatable, with screw-threaded parts connecting the bearings, the male member of the thread being narrower at the end first engaging, than the female member, thereby permitting longitudinal play before the threads actively engage, substantially as and for the purpose set forth.

4. The combination of a coiled spring mounted in bearings, one or both of which are rotatable, with screw-threaded parts connecting the bearings, the pitch of the threads being in a reverse direction to the coil of the spring and the male member of the thread being narrower at the end first engaging than the female member, thereby permitting longitudinal play before the threads actively engage, substantially as and for the purpose set forth.

5. The combination of a hollow plunger; a housing adapted to receive the plunger; a coiled spring within the plunger having one end adapted to engage the plunger and the other adapted to engage the housing; screw-threads on the plunger and housing whereby the spring may be wound as it is compressed, and stops adapted to prevent complete compression of the spring, substantially as and for the purpose set forth.

6. The combination of a hollow plunger; a housing adapted to receive the plunger; a coiled spring within the plunger having one end adapted to engage the plunger and the other adapted to engage the housing; screw-threads on the plunger and housing whereby the spring may be wound as it is compressed; the pitch of the threads being in a direction reverse to that of the coil of the spring, and the male member being narrower, for a portion of its length, than the female member, and stops adapted to limit the compression of the spring, substantially as and for the purpose set forth.

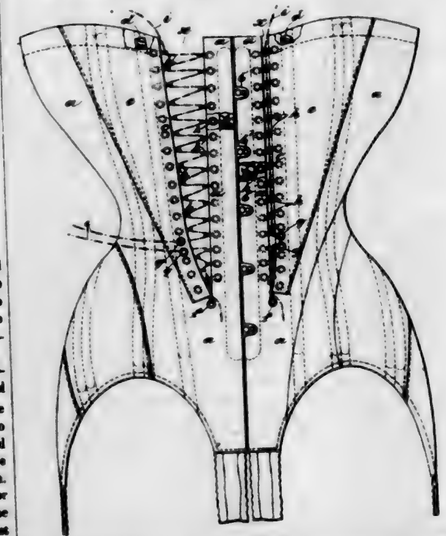
7. The combination of a hollow plunger; a housing adapted to receive the plunger; friction-heads on the plunger and housing; a coiled spring within the plunger having one end adapted to engage with and be rotated by the friction-head on the plunger and the other end adapted to engage with and be rotated in the reverse direction by the friction-head on the housing; and screw-threads on the plunger and housing whereby the spring may be wound as it is compressed, substantially as and for the purpose set forth.

8. The combination of a hollow plunger; a housing adapted to receive the plunger; friction-heads on the plunger and housing; a coiled spring within the plunger having one end adapted to engage with and be rotated by the friction-head on the plunger and the other end adapted to engage with and be rotated in the reverse direction by the friction-head on the housing; screw-threads on the plunger and housing whereby the spring may be wound as it is compressed, and stops limiting the compression of the spring, substantially as and for the purpose set forth.

9. The combination of the plunger B; the housing C; the heads *g* and *h*; the screw-threads *g'* and *h'*; the sockets g^2 and h^2; and the coiled spring F having back-turned ends *f*, substantially as and for the purpose set forth

---

706,807. CORSET. EUGÈNE FAREY, Paris, France, assignor to Ste. des Etablissements Farey et Oppenheim, Paris, France. Filed Jan. 9, 1902. Serial No. 88,958. (No model.)



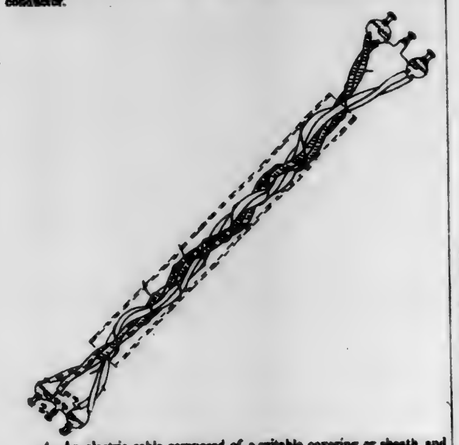
Claim.—A corset, open at the median line in front and provided thereat with busks or steels and clasps, and having at the respective opposite sides of said busks slits *a a* which extend only part way down from the top of the corset to the bottom thereof, lacing devices along the margins of said slits, lacing-cords engaging said lacing devices, eyelets *f* at the lower ends of the slits for securing the lacing-cords, and pairs of eyelets *g* at the waist through which the cords extend, as and for the purpose set forth.

706,808. TELEPHONE-CIRCUIT. MARIA J. FARRAR, Wellesley, Mass., administratrix of Josiah H. Farrahar, deceased, assignor to New England Telephone & Telegraph Company, a Corporation of New York. Filed July 2, 1901. Serial No. 66,982. (No model.)

Claim.—1. A plurality of pairs of paper-insulated conductors, the conductors of each pair evenly and equally twisted together throughout their length, and each twisted pair evenly and equally twisted with another twisted pair, the said two pairs that are twisted together being insulated from any other conductor.

2. A plurality of pairs of paper-insulated conductors, the conductors of each pair evenly and equally twisted together throughout their length, and each twisted pair evenly and equally twisted with another twisted pair, but in a direction reverse to that of the individual pairs, the said two pairs that are twisted together being insulated from any other conductor.

3. An electric cable composed of a suitable covering or sheath, and a plurality of inclosed pairs of insulated conductors, the conductors of each pair evenly and equally twisted together throughout the length thereof, and each twisted pair equally twisted with another twisted pair, the two said pairs that are twisted together being insulated from any other conductor.



4. An electric cable composed of a suitable covering or sheath, and a plurality of inclosed pairs of insulated conductors, the conductors of each pair evenly and equally twisted together throughout the length thereof, and each twisted pair equally twisted with another twisted pair, but in a direction reverse to that of the said pairs, the said two pairs that are twisted together being insulated from any other conductor.

5. A plurality of pairs of electric circuits, the conductors of each pair evenly and equally twisted together throughout their length, and each twisted pair evenly and equally twisted with another twisted pair; with an impedance-coil at the terminals of each twisted pair and in a bridge between the conductors thereof dividing the circuit into sections, one section provided with signaling instruments, with a connecting branch between the centers of the impedance-coil windings of two circuits adapted to contain signaling instruments.

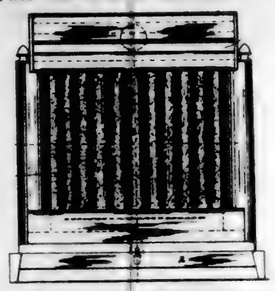
6. A plurality of pairs of electric circuits, the conductors of each pair evenly and equally twisted throughout their length, and each twisted pair evenly and equally twisted with another twisted pair; with an impedance-coil at the terminals of each twisted pair and in a bridge between the conductors thereof dividing the circuit into sections, one section provided with signaling instruments, with a connecting branch between the centers of the impedance-coil windings of two circuits to constitute a third circuit, the said branch adapted to contain signaling instruments.

7. A plurality of pairs of electric circuits, the conductors of each pair evenly and equally twisted throughout their length, and each twisted pair evenly and equally twisted with another pair; with an impedance-coil at the terminals of each twisted pair and in a bridge between the conductors thereof dividing the circuit into sections, one section provided with signaling instruments, current from which is adapted to circulate in the helices of the said coil-winding in series, with a connecting branch between the centers of the impedance-coil windings of two circuits to constitute a third circuit, the said branch containing signaling instruments, current from which is adapted to circulate in the helices of the coil-windings of the two circuits differentially.

8. A plurality of pairs of electric circuits, the conductors of which are evenly and equally twisted together throughout their length; with an impedance-coil at the terminals of the conductors and in a bridge between the conductors of each pair dividing the circuit into sections, one section provided with signaling instruments, with a connecting branch between the centers of the impedance-coil windings of two circuits adapted to contain signaling instruments.

9. A plurality of pairs of electric circuits, the conductors of which are evenly and equally twisted together throughout their length; with an impedance-coil at the terminals of the conductors and in a bridge between the conductors of each pair, dividing the circuit into sections, one section provided with signaling instruments as telephones, with a connecting branch between the centers of the impedance-coil windings of two circuits to constitute a third circuit the respective conductors of each pair of circuits forming the limbs thereof, the said branch adapted to contain signaling instruments as telephones.

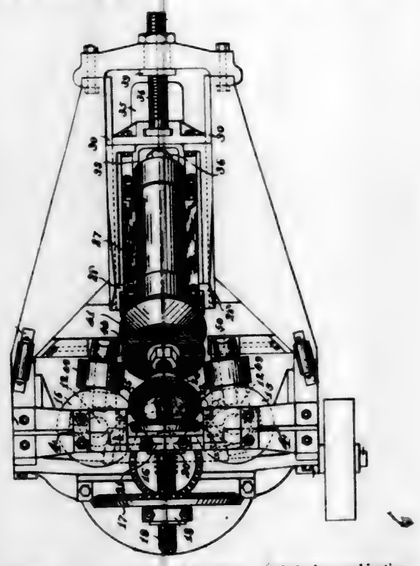
706,809. GAS-STOVE. JOHN C. FORSTER, Pittsburg, Pa. Filed Jan. 25, 1902. Serial No. 91,194. (No model.)



Claim.—1. In a gas-stove, a fire-board having a vertically-corrugated fire-surface, and a gas connection having gas-emitting openings arranged complementary to the said corrugated fire-surface.

2. In a gas-stove, a fire-board having a vertically-corrugated fire-surface, and a horizontal burner positioned transversely of the fire-board at the base thereof, said burner being formed with gas-emitting openings arranged in a winding or serpentine course complementary to the said corrugated fire-surface.

706,810. MACHINE FOR BENDING ANGLE-IRONS, CHANNEL-IRONS, &c. CHARLES GABRIEL, Chicago, Ill. Filed July 12, 1901. Serial No. 66,039. (No model.)



Claim.—1. In a machine of the kind specified, the combination with a driven shaft mounted in a bearing movable in two directions and carrying a roller, of two driven rollers mounted on shafts journaled in bearings movable relatively to each other and to said first-named shaft, said rollers on said shafts being adapted to bear on the bar to be bent at three different points to bend the same.

2. In a machine of the kind specified, the combination with a shaft standing at an angle of forty-five degrees to a vertical line and carrying bevel-faced rollers, of two pairs of rollers turning on vertical and horizontal axes respectively and journaled in movable bearings, said rollers being adjusted relatively to each other and to said bevel-faced roller to coact with the latter to bear upon and bend a bar to any desired single or compound curvature.

3. In a machine of the kind specified, the combination with two pairs of rollers revoluble on horizontal and vertical axes respectively, of a shaft standing at an angle of forty-five degrees to the axes of rotation of each of said pairs of rollers, a sleeve-bearing carrying said shaft, a frame

in which said sleeve-bearing is longitudinally movable, guides in the frame of the machine in which said frame carrying said bearing is movable in a direction at an angle to the direction of movement of said sleeve-bearing, and bevel-faced rollers carried by said shaft and coacting with said pairs of rollers respectively to bear upon the bar to be bent to bend the latter.

4. In a machine of the kind specified, the combination with a frame, a drive-shaft journaled therein, a curved guide on said frame concentric with said shaft, bearings movably mounted on said guide, shafts journaled in said bearings and carrying spur-gears, a pinion on said drive-shaft intermeshing with each of said spur-gears, and rollers carried by said shafts, of a shaft journaled in a bearing on said frame and carrying a roller coacting with said first-named rollers to bear upon and bend a bar.

5. In a machine of the kind specified, the combination with a frame, a drive-shaft journaled therein, a curved guide on said frame concentric with said shaft, bearings movably mounted on said guide, shafts journaled in said bearings and carrying spur-gears, a pinion on said drive-shaft intermeshing with each of said spur-gears, and rollers carried by said shafts, of a shaft journaled in a bearing on said frame and carrying a roller coacting with said first-named rollers to bear upon and bend a bar, and gearing between said last-named shaft and said drive-shaft.

6. In a machine of the kind specified, the combination with a frame, a drive-shaft journaled therein, a curved guide on said frame concentric with said drive-shaft, bearings movably mounted on said guide, counter-shafts journaled in said bearings, gearing between said drive-shaft and said counter-shafts, rollers carried by said counter-shafts, bearings pivotally secured to said counter-shafts, shafts journaled in said pivoted bearings extending transversely to said counter-shafts, and rollers on said transverse shafts, of a shaft carrying rollers coacting with the rollers on said counter-shafts and said transverse shafts to bear upon and bend a bar.

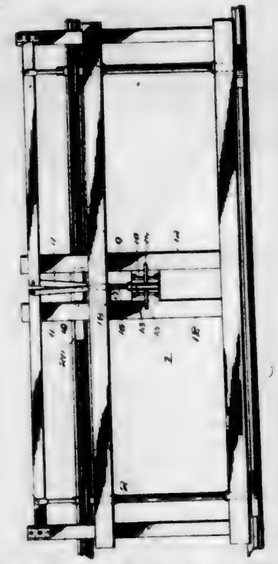
7. In a machine of the kind specified, the combination with a frame, a drive-shaft journaled therein, a curved guide on said frame concentric with said drive-shaft, bearings movably mounted on said guide, counter-shafts journaled in said bearings, gearing between said drive-shaft and said counter-shafts, rollers carried by said counter-shafts, bearings pivotally secured to said counter-shafts, shafts journaled in said pivoted bearings extending transversely to said counter-shafts, and rollers on said transverse shafts, of a shaft carrying rollers coacting with the rollers on said counter-shafts and said transverse shafts to bear upon and bend a bar, and means for adjusting said last-named shaft relatively to said counter-shafts and transverse shafts to bring said rollers thereon into the desired position relatively to said rollers on said counter and transverse shafts.

8. In a machine of the kind specified, the combination with a frame, a drive-shaft journaled therein, a curved guide on said frame concentric with said drive-shaft, bearings movably mounted on said guide, counter-shafts journaled in said bearings, gearing between said drive-shaft and said counter-shafts, rollers carried by said counter-shafts, bearings pivotally secured to said counter-shafts, shafts journaled in said pivoted bearings extending transversely to said counter-shafts, and rollers on said transverse shafts, of a frame movable in guides in the frame of the machine transversely to said drive-shaft, a sleeve-bearing mounted in guides in said movable frame movable longitudinally in said guides and extending at an angle of forty-five degrees to said drive-shaft, a shaft journaled in said bearing, gearing between said shaft and the drive-shaft, and bevel-faced rollers mounted on said shaft and adapted to coact with said rollers on said counter-shafts, and drive-shafts to bend a bar in one or more directions.

9. In a machine of the kind specified, the combination with a pair of rollers revoluble on vertical axes and adapted to bear upon the bar to be bent on one face, and a pair of rollers revoluble on horizontal axes and adapted to bear upon the bar to be bent on a face transverse to the face engaged by said first-named rollers, of a shaft extending at an angle of forty-five degrees to the vertical axes of said first-named rollers, an adjustable sleeve-bearing carrying said shaft and movable horizontally and longitudinally, and a grooved roller carried by said shaft and having one face overhanging and adapted to coact with said horizontal rollers and engage the face of the bar opposite to that engaged by said horizontal rollers, and having a beveled face in horizontal alinement with said vertical rollers and adapted to engage the face of the bar opposite that engaged by said vertical rollers, said beveled faces being adapted to bear upon the bar at points practically midway between the points of engagement of said vertical, and horizontal rollers respectively, and forming a third bearing-point relatively to each of said pairs.

706,811. OFFSET MECHANISM FOR SAWMILL-CARRIAGES. JOHN J. GALWAY, Duluth, Minn., assignor of one-half to Kenneth McDonald, Duluth, Minn. Filed Apr. 16, 1902. Serial No. 103,204. (No model.)

Claim.—1. An offset mechanism for sawmill-carriages, comprising means for moving a carriage laterally upon its trucks, fulcrums projecting beyond the trucks, levers arranged longitudinally of the carriage and connected at one of their ends with the carriage-frame, the said levers being pivoted to said extended fulcrums, and means for moving the other ends of the said levers for shifting the carriage upon the trucks, substantially as described.



2. An offset mechanism for sawmill-carriages, comprising a carriage movably mounted on the axles of suitable trucks, fulcrum-pieces projecting from the ends of said axles, comparatively long levers pivoted to said fulcrum-pieces, the outer ends of said levers being connected with the carriage-frame, a power mechanism carried by the truck and connected with the inner ends of said levers for simultaneously moving them to shift the position of the carriage upon its trucks, substantially as described.

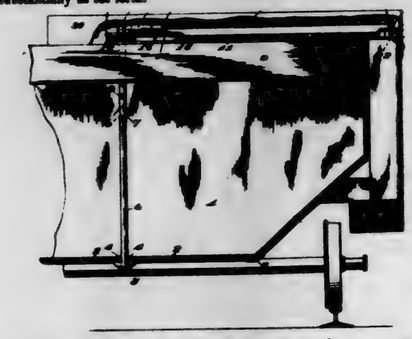
3. An offset mechanism for sawmill-carriages, comprising a frame, trucks supporting the same, extension-pieces on the ends of the truck-axles, forming fulcrum-pieces, levers arranged longitudinally of the carriage outside the wheels thereof and pivoted to the fulcrum-pieces, the outer ends of the levers being connected with the carriage, a power-cylinder carried by the carriage, a piston moving therein, means connecting the inner ends of the said levers with the said pistou, the power means thus being capable of simultaneously moving the said levers, to offset the carriage, and means operated by the movement of the carriage for controlling the application of power in the power-cylinder, substantially as described.

4. An offset mechanism for sawmill-carriages, comprising comparatively long levers pivoted to the ends of the carriage-axles, means for connecting both the inner ends of the said levers with a power mechanism, a valve mechanism for controlling the power mechanism, and a drag engaging one of the tracks in which the carriage travels for automatically operating the valve mechanism in accordance with the direction in which the carriage is moved, substantially as described.

5. An offset mechanism for sawmill-carriages, comprising levers extending longitudinally of the carriage and pivoted thereto at their outer ends, fulcrum-pieces projecting from the axles of the carriage so as to support the said levers at points near their connections with the said carriage, a power-cylinder carried by the carriage, means for connecting its piston with the inner adjacent ends of the levers at a suitable distance from their fulcrum-points, a valve for controlling the application of power to said cylinder, a comparatively light drag-block fitting upon one of the tracks of the carriage, a bell-crank lever connecting the same with the valve mechanism of the power-cylinder so that the valve will be controlled for admitting pressure to the piston in accordance with the direction in which the carriage is traveling, substantially as described.

706,812. DEVICE FOR SECURING OR RELEASING TRAP-FLOORS FOR ORE-CARS. JOHN J. GALWAY, Duluth, Minn. Filed Mar. 25, 1902. Serial No. 99,044. (No model.)

Claim.—1. The combination with a car provided with trap-doors, of a rod designed to support the same in a closed position, means for locking said rod, devices for releasing said rod's locking means, mechanism for rotating the rod after it is released, and devices connected with said rotating mechanism, adapted, upon reciprocation, to impart such rotation, substantially as set forth.



2. The combination with a car having trap-doors, of means supported within said car for locking said doors in a closed position, mechanism for rotating said locking means, and a reciprocating lever adapted to operate said rotating mechanism, substantially as set forth.

3. The combination with a car having trap-doors, of means supported within said car for locking said doors in a closed position, mechanism for rotating said locking means, such mechanism comprising a ratchet, a lever, a pawl carried by said lever for operating said ratchet, and a second reciprocating lever for actuating the pawl-carrying lever, substantially as set forth.

4. The combination with a car having trap-doors, of a rod held against longitudinal movement and provided with means for supporting said doors in a closed position, a joint formed intermediate the length of said rod, and means for rotating said rod for releasing said door, substantially as described.

5. The combination with a car having trap-doors, of means supported within said car for locking said doors in a closed position, a lever engaging said locking means, and means carried by said lever for releasing the locking means such means comprising a vertically-reciprocating lever connected at one end to first said lever, substantially as described.

6. In a mechanism of the class described the combination with a suitable car having trap-doors, of a rod supporting said doors in a closed position in such manner as to release the same upon rotation, a lever for rotating said rod, and means extending outside said car for operating said lever, substantially as described.

7. In a mechanism of the class described the combination with a suitable car having trap-doors, of a rod supporting said door in a closed position in such manner as to release the same upon rotation, means for locking said rod against rotation, means for releasing said locking means, and means for rotating said rod, substantially as described.

8. In a mechanism of the class described the combination with a suitable car having trap-doors, of means supporting the same in a closed position in such manner as to release the same upon rotation of the supporting means, a ratchet-wheel carried by said supporting means, means for locking said ratchet-wheel against rotation, and means extending outside said car for releasing said locking means and rotating said ratchet-wheel, substantially as described.

9. In a mechanism of the class described the combination with a suitable car having trap-doors, of a rod supporting the same in such manner as to effect their release upon rotation, a ratchet-wheel carried by said rod, a lever pivoted within said car and provided with a pawl engaging said ratchet, and means for swinging said lever upon its pivot for rotating said ratchet-wheel, substantially as described.

10. In a mechanism of the class described the combination with a suitable car having trap-doors, of a rod supporting the same in their closed position in such manner as to effect their release upon rotation, means for locking said rod against rotation, a lever for rotating said rod, and a rod engaging both the locking means and said lever for manipulating the same, substantially as described.

11. In a mechanism of the class described the combination with a suitable car having trap-doors, of a rod supporting the same in such manner as to effect their release upon rotation, said rod being formed with a groove in its upper end, a bolt normally engaging said groove for preventing the rotation of said rod, means for withdrawing the said bolt, and means for rotating said rod, substantially as described.

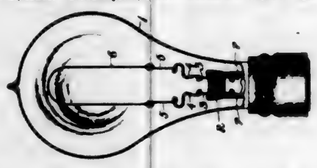
12. In a mechanism of the class described the combination with a suitable car having trap-doors, of a rod supporting the same in such manner as to effect their release upon rotation, a lever bifurcated and having the arms of its bifurcation pivotally engaging said rod, a ratchet-wheel secured to said rod between the arms of said bifurcation, a pawl pivotally attached to said lever, and means for retaining said pawl in engagement with said ratchet-wheel, substantially as described.

13. In a mechanism of the class described the combination with a suitable car having trap-doors, of a rod supporting the same in such manner as to effect their release upon rotation, a bolt engaging said rod for preventing rotation thereof and provided with an eye at its free end, a lever engaging said rod for rotating the same, a rod engaging the said lever for operating the same, and a bent arm carried by said last-mentioned rod and engaging the eye of said bolt, substantially as described.

14. In a mechanism of the class described the combination with a suitable car having trap-doors, of a rod supporting the same in such manner as to effect their release upon rotation, means for locking said rod against rotation, a lever for rotating said rod having its outer end bifurcated, a swivel-block pivotally mounted between the arms of said bifurcation, and a rod engaging said swivel-block and provided with means engaging said locking means for manipulating the parts, substantially as described.

15. In a mechanism of the class described the combination with a suitable car having trap-doors, of a rod supporting the same in such manner as to effect their release upon rotation, a bolt jointed intermediate its length, a guiding-box inclosing a portion of said bolt beyond the joint, that portion of said bolt beyond the guiding-box being designed to engage said rod for preventing rotation thereof, means for disengaging said bolt from said rod, and means for rotating said rod, substantially as described.

706,818. INCANDESCENT ELECTRIC LAMP. HOWARD GILMORE, Boston, Mass. Filed Apr. 7, 1900. Serial No. 11,967. (No model.)

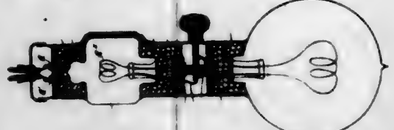


Claim.—1. The improved electric lamp above described comprising a filament and a short piece of wire 5 coiled at both ends, with one end of the filament connected and secured to one coil of wire 5, and a second short piece of wire 4, connected and secured to the other coil of wire 5.

2. In an incandescent electric lamp a leading-in wire comprising a piece of wire (such as platinum or nickel) coiled at one end and another piece of more fusible wire such as copper with its end in that coil and held therein by a melted portion of the more fusible metal flowing into the coil and cooling between the spires of the coil and the wire within the coil.

3. In an incandescent lamp a filament with one end connected by a body part B and carbon deposited on that body part to a coil on one end of a short piece of wire 5, and with a coil on the other end of that wire 5, connected and secured to another short piece of wire 4.

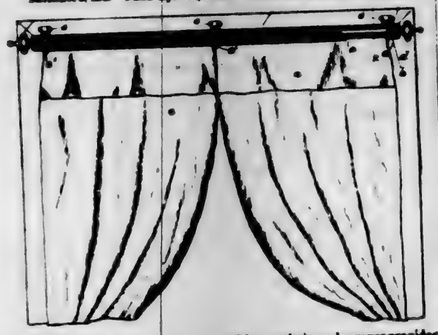
706,814. COMPOUND INCANDESCENT ELECTRIC LAMP. HOWARD GILMORE, Boston, Mass. Filed Feb. 7, 1901. Serial No. 46,413 (No model.)



Claim.—1. In combination two incandescent lamps one with a fine filament the other with a coarser filament and means for passing the current through the lamp with the coarser filament to bring that lamp alone to full glow, and means for passing the current through both lamps in series and so reduce the amperage that only the lamp with the fine filament will be brought to full glow.

2. An incandescent electric lamp comprising a bulb, a filament in that bulb, one set of contacts comprising three contact-pieces and another set of contacts comprising two contact-pieces, with two contact-pieces of the three-piece set connected respectively to the terminals of the filament and one of these two contact-pieces connected also to one contact of the two-piece set; having one contact of the three-piece set and one contact of the two-piece set to be connected respectively with the main wires.

706,815. CURTAIN-POLE AND HANGER. SAMUEL G. GREENE, Baltimore, Md. Filed Apr. 14, 1902. Serial No. 103,726. (No model.)

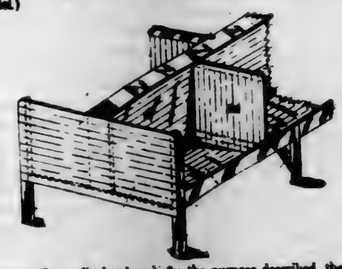


Claim.—1. A curtain-pole, comprising a tubular pole proper provided with a longitudinal slot; a rod over which the curtain is intended to be hung and said rod inserted in said tubular pole with the curtain extending out through said slot; and means for positively pressing said rod toward said slot whereby to pinch the curtain between the rod and edge walls of the slot, as set forth.

2. A curtain-pole, comprising a tubular pole proper provided with a longitudinal slot; a rod over which the curtain is intended to be hung and said rod adapted for insertion in said tubular pole; and end caps provided with a wedge or plug entered in the tubular pole and wedging between the internal wall of the pole and the ends of said rod whereby to press said rod toward said slot, as and for the purpose set forth.

3. A curtain-pole, comprising a tubular pole proper provided with a longitudinal slot; a rod over which the curtain is intended to be hung and said rod inserted in said tubular pole with the curtain extending out through said slot; and plugs wedging in said pole between said rod and that internal wall of the pole which is opposite said slot, whereby to positively press said rod toward the slot, as set forth.

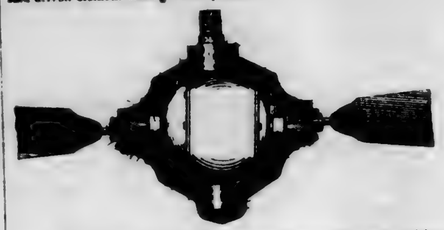
706,816. DISPLAY-BENCH FOR DOG-SHOWS. ROBERT B. HARRELL, Baltimore, Md. Filed Apr. 18, 1902. Serial No. 103,569. (No model.)



Claim.—In a display-bench for the purpose described, the combination of two heads having suitable supporting legs and stringers at their lower edges, a floor extending between the heads and supported at its ends by the said stringers, a rail at each lateral edge of the floor, a longitudinal partition erected on the floor with its ends adjoining the heads, a cap-plate laid on the edge of the longitudinal partition, vertical cross-partitions which extend between the longitudinal partition and the rails, and a series of removable clips which clamp the rear and front edges of the said partitions to the cap-plate and the rails respectively and adapted to slide thereon in the adjustment of the said cross-partitions longitudinally of the bench, substantially as specified.

706,817. ELECTRIC MOTOR. ALBERT B. HOLSON, Chicago, Ill. Filed Nov. 4, 1901. Serial No. 81,076. (No model.)

Claim.—1. In an electric motor, the combination of a rotary armature, a drive-shaft rotating therewith, a pinion on each end of said shaft and a surrounding driven member provided with duplex parallel annular gears having their pinion-engaging surfaces facing toward each other and respectively engaged with said pinions in diametrically opposite relation, whereby the driving moment of the motor is simultaneously imparted to said driven element through both pinions.



2. In an electric motor, the combination of a rotary armature, a drive-shaft rotating therewith, a friction-pinion on each end of said shaft and a surrounding driven member provided with duplex parallel annular friction-surfaces arranged to face each other and respectively engaged with said pinions in diametrically opposite relation whereby the driving moment of the motor is simultaneously imparted to said driven element through both pinions.

3. In an electric motor, the combination of a rotary armature, a drive-shaft rotating therewith, a pinion on each end of said shaft, a surrounding driven member provided with duplex parallel annular gears having their pinion-engaging surfaces facing each other and respectively engaged with said pinions in diametrically opposite relation, said gears being adjustable toward and from each other whereby the engagement of the pinions therewith may be adjusted, substantially as described.

4. In an electric motor, the combination of a rotary armature provided with a drive-shaft rotating therewith, a pinion on each end of said shaft, a relatively stationary frame within which the ends of said armature-shaft are journaled, and whereby the armature is held in fixed relation to the frame, and a surrounding driven element journaled upon said frame, and provided with duplex parallel annular gears having their pinion-engaging surfaces facing each other and respectively engaged with said pinions in diametrically opposite relation, whereby the driving moment of the motor is simultaneously imparted to said driven element through both pinions.

5. In an electric motor, the combination of a rotary armature provided with a drive-shaft rotating therewith, a pinion on each end of said shaft, a relatively stationary frame within which the ends of said armature-shaft are journaled, and whereby the armature is held in fixed relation to the frame, and a surrounding driven element journaled upon said frame, and provided with duplex parallel annular gears having their pinion-engaging surfaces facing each other and respectively engaged with said pinions in diametrically opposite relation, whereby the driving moment of the motor is simultaneously imparted to said driven element through both pinions, said driven element being separable and the members thereof adjustably united, and each of said members carrying one of the gears, whereby the latter may be adjustable relatively to each other for the purpose set forth.

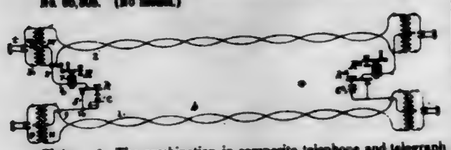
6. In an electric motor, the combination of a relatively stationary frame of hollow construction, a series of field-pieces supported upon the interior of said frame, an armature having an armature-shaft journaled within said frame and provided at each end externally of the frame with a pinion, a shell-like driven member inclosing said stationary frame and journaled to rotate thereon, a pair of parallel, annular gears having their pinion-engaging surfaces facing each other, rigidly mounted within said shell and respectively engaged with the pinions of the armature-shaft, and means for adjusting one of said gears relatively to the other, for the purpose set forth.

7. In an electric fan, the combination of a relatively stationary frame of hollow construction, a series of field-pieces supported upon the interior of said frame, an armature having an armature-shaft journaled within said frame and provided at each end externally to the frame with a friction-pinion, a shell-like driven member inclosing said stationary frame and journaled to rotate thereon, a pair of parallel, annular friction-gears having their pinion-engaging surfaces facing each other, rigidly mounted within said shell and respectively engaged with the pinions of the armature-shaft at diametrically opposite points, means for adjusting one of said gears relatively to the other, fan-blades mounted upon said outer shell and suitable electric connections for the motor, substantially as set forth.

8. In an electric fan, the combination of a hollow stationary frame member provided at diametrically opposite points with trunnion-like lour-

nal-bearings, an armature provided with an armature-shaft journaled in said stationary frame with its axis inclined slightly from a position at right angles to the axis of said trunnion-like journals, a friction-pinion upon each end of said armature-shaft, an inclosing shell having its opposite sides journaled upon said trunnion-like journals and provided upon its interior with a pair of parallel, annular friction-surfaces, said shell being made of two-part construction and separably in a plane extending between said annular friction-surfaces, means for adjusting one shell member upon the other to approach or separate said annular friction-surfaces and fan-blades mounted upon the exterior of the shell, substantially as described.

706,818. COMPOSITE ELECTRIC CIRCUIT. MARTIN H. HOWELL, Melrose, Mass., assignor to New England Telephone and Telegraph Company, a Corporation of New York. Filed June 24, 1901. Serial No. 65,803. (No model.)



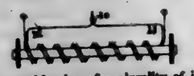
Claim.—1. The combination in composite telephone and telegraph circuits, of a metallic circuit whose conductors are transposed relatively to each other between their terminals, a repeating-coil at each end of the circuit whose windings are inductive to telephone-currents and non-inductive to telegraph-currents, the telephone-currents adapted to traverse the helices of the windings in series, and the telegraph-currents adapted to circulate in the helices of the windings differentially, with telephones in series with one of the windings of each coil, and telegraph instruments connected to the center of the second winding of the coil, as set forth.

2. The combination in composite telephone and telegraph circuits, of a metallic circuit whose conductors are transposed relatively to each other between their terminals, a repeating-coil at each end of the circuit whose windings are inductive to telephone-currents and non-inductive to telegraph-currents, the telephone-currents adapted to traverse the helices of the windings in series, and the telegraph-currents adapted to circulate in the helices of the windings differentially, telephones in series with one of the windings of each coil, and telegraph instruments connected to the center of the second windings of each coil, with one or more repeating-coils in the line-circuit between the said end coils having extensions from the centers of both windings of each coil adapted to include telegraph instruments.

3. The combination in composite telephone and telegraph circuits; of a metallic circuit whose conductors are transposed relatively to each other between their terminals; a repeating-coil at each end of the circuit whose windings are inductive to telephone-currents and non-inductive to telegraph-currents, the former currents being adapted to traverse the helices of the windings in series, and the latter currents adapted to circulate in one of said winding differentially; with telephones in a local circuit with one of said windings, and telegraph instruments connected to the center of the second winding, as set forth.

4. The combination in composite telephone and telegraph circuits, of a metallic circuit whose conductors are transposed relatively to each other between their terminals, a repeating-coil at each end of the circuit whose windings are inductive to telephone-currents and non-inductive to telegraph-currents, the telephone-currents adapted to traverse the helices of the windings in series, and the telegraph-currents adapted to circulate in the helices of the windings differentially, telephones in series with one of the windings of each coil, and telegraph instruments connected to the center of the second windings of each coil, with one or more repeating-coils in the line-circuit between the said end coils the centers of the windings of each coil being connected and including in circuit telegraph instruments, as set forth.

706,819. TELEPHONE-CIRCUIT. MARTIN H. HOWELL, Melrose, Mass., assignor to New England Telephone and Telegraph Company, a Corporation of New York. Filed June 19, 1901. Serial No. 65,137. (No model.)



Claim.—1. The combination of a plurality of insulated conductors inclosed in a protective sheath, twisted together in pairs to form independent metallic circuits, each pair twisted with a second pair; with a repeating-coil at the terminal of each pair of conductors and provided with an extension from the center of the main-circuit windings to constitute a third instrument-circuit.

2. The combination of a plurality of insulated conductors inclosed in a protective sheath, twisted together in pairs to form independent metallic circuits, each pair twisted with a second pair in a direction reverse to their own twist, with a repeating-coil at the terminals of each pair of conductors whose windings are twisted together and provided with an extension from the center of the main-circuit windings to constitute a third instrument-circuit.

3. The combination of a plurality of insulated conductors inclosed in a protective sheath, twisted together in pairs to form independent metallic circuits each pair twisted with a second pair; with a repeating-coil at the terminals of each pair of conductors whose windings are twisted together and are in inductive relation respectively to the main circuits and to their local instrument-circuits, and provided with an extension from the center of the main-circuit windings to constitute a third instrument-circuit.

4. The combination of a plurality of insulated conductors inclosed in a protective sheath, twisted together in pairs to form independent metallic circuits, each pair twisted with a second pair in a direction reverse to their own twist; with a repeating-coil at the terminals of each pair of conductors whose windings are twisted together and provided with an extension from the center of the main-circuit windings to constitute a third instrument-circuit.

5. The combination of a plurality of insulated conductors inclosed in a protective sheath, twisted together in pairs to form independent main circuits having telephones at each terminal thereof, a repeating-coil at the said terminals of each pair, the said windings being twisted together and having an extension from the center of the main-circuit windings to include telephones and to form a third circuit, each pair of conductors constituting a metallic circuit and twisted with a second pai , as set forth.

6. The combination of four insulated conductors twisted together in pairs to form independent main metallic circuits, each pair twisted with the other pair; with a repeating-coil at the terminals of the pairs of conductors and provided with an extension from the center of the main-circuit windings to constitute a third instrument-circuit, as set forth.

7. The combination of four insulated conductors twisted together in pairs to form independent main metallic circuits, each pair twisted with the other pair; with a repeating-coil at the terminals of the pairs of conductors, and provided with an extension from the center of the main-circuit winding, to constitute a third circuit including telephones, as set forth.

8. The combination of a plurality of conductors transposed in pairs to form independent metallic circuits; with a repeating-coil at the terminal of each pair of conductors and provided with an extension from the center of the main-circuit windings to constitute a third instrument-circuit.

9. The combination of a plurality of telephone-circuits extending between terminal stations, two or more of which circuits are insulated and contained in a protective sheath for a portion of their length, and for the remainder of the distance are non-insulated and supported upon pins in the air; the said insulated portions of the circuits being twisted in pairs to form independent metallic circuits, each pair twisted with a second pair, and the non-insulated continuations of said pairs are transposed upon said pins; with a repeating-coil at the terminal of each pair of conductors and to their local instrument-circuits and provided with an extension from the center of the main-circuit windings to constitute a third instrument-circuit.

10. A repeating-coil for electric circuits, one or both of whose inductive windings consist of twisted conductors both of the windings provided with end terminals and one winding having a central terminal.

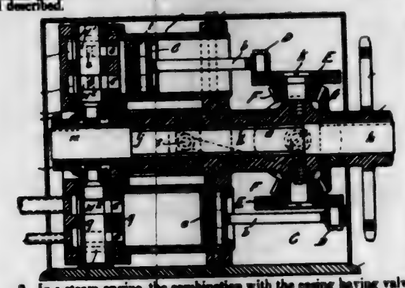
11. A repeating-coil for electric circuits, one or both of whose inductive windings consist of twisted conductors whose terminals are so connected that the circuit therethrough continues through the conductors twice in series, with an extension from the center of the windings.

12. A repeating-coil for electric circuits whose inductive windings consist of double-twisted conductors, the circuits through each winding continuing through the helices twice in series, with an extension or terminal from the center of one of the windings.

13. A repeating-coil for composite electric circuits consisting of three windings composed of several conductors wound together, the helices of one winding in series from one terminal to the other and inductive to alternating or telephone currents, the helices of the second winding provided with end terminals and a third terminal from the center thereof, the said winding inductive to alternating or telephone currents traversing its helices in series, and non-inductive to such currents circulating therein differentially, and the third winding consisting of one or more helices adapted to be grounded at one terminal and open at the other.

706,820. STEAM-ENGINE. JAMES A. JENNEY, Providence, R. I. Filed May 9, 1901. Serial No. 59,484. (No model.)

Claim.—1. In a steam-engine, the combination with the casing and the driving-shaft, of a plurality of equidistant cylinders arranged about said casing parallel with the driving-shaft, pistons in said cylinders, crank-disks, pivoted connecting-rods connecting the disks and pistons, bevel-gears fixed to said disks, a larger bevel-gear on the driving-shaft meshing with said bevel-gears, valve-chambers at one end of the casing, rotatable valves in said chambers a gear on the driving-shaft and gears on the stems of the said valves meshing with said gear, all substantially as shown and described.



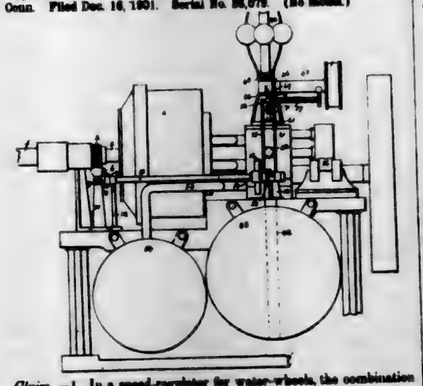
2. In a steam-engine, the combination with the casing having valve-chambers at one end, and the driving-shaft, of a plurality of equidistant cylinders arranged about said casing parallel with the driving-shaft, pistons in said cylinders, crank-disks, pivoted connecting-rods connecting the crank-disks and pistons, bevel-gears fixed to said disks, a larger bevel-gear on the driving-shaft meshing with said bevel-gears, rotatable valves in said valve-chambers, a gear on the driving-shaft, gears on the stems of the valves meshing with said gear, and means for adjusting the last-mentioned gear to readjust the said valves, as set forth.

3. In a steam-engine, the combination with a plurality of cylinders of pistons, and their connecting-rods, crank-disks rotated by said connecting-rods, gears fixed to the crank-disks, a larger gear on the driving-shaft, a driving-shaft, a shaft-casing upon which said disks and gears are supported, and a gear fixedly mounted upon the driving-shaft meshing with the said gears, rotatable valves and gears carried by the stems thereof and meshing with the larger gear on the driving-shaft.

4. In a steam-engine, the combination with a plurality of cylinders circularly arranged about the driving-shaft of a plurality of cylindrical valves governing the engine-ports and radiating from the driving-shaft, gears upon the inner ends of valve-stems, a driving-shaft, and a large gear mounted thereon meshing with the smaller gears, means for adjusting said larger gear, and a sprocket-wheel on the outer end of the driving-shaft.

5. In a steam-engine, the combination of the cylinders, arranged parallel with the driving-shaft, the pistons therein, a series of cylindrical valves, radially disposed in relation to a central driving-shaft, each valve being provided with a plurality of transverse slots located one above the other upon opposite sides of the valves, a driving-shaft, and a sprocket-wheel on the outer end of said shaft and means connected with said driving-shaft for simultaneously rotating the valves, and means for adjusting said valves.

706,821. SPEED-REGULATOR. JOSEPH R. JOHNSON, Meriden, Conn. Filed Dec. 16, 1901. Serial No. 86,079. (No model.)



Claim.—1. In a speed-regulator for water-wheels, the combination with a water-wheel-gate controller, of a governor, operating connections between the governor and controller, and connections between the controller and the governor, including a friction-clutch.

2. In a speed-regulator for water-wheels, the combination with a water-wheel-gate controller, of a governor, operating connections between the said governor and controller, connections between the controller and the governor including a friction-clutch, and an operating-bar connected with and operated by the governor to cause the friction-clutch to come into action.

3. In a speed-regulator for water-wheels, the combination with a water-wheel-gate controller, of a governor, operating connections between the governor and controller, connections between the controller and the governor including a friction-clutch, an operating-bar connected with and operated by the governor to cause the friction-clutch to come into action, and an operating-lever operated by the said bar to bring the friction-clutch into play.

4. In a speed-regulator for water-wheels, the combination with a water-wheel-gate controller, of a governor, operating connections between the governor and controller, connections between the controller and the governor including a friction-clutch, an operating-bar connected with and operated by the governor to cause the friction-clutch to come into action, an operating-lever operated by the said bar to bring the friction-clutch into play, and means operated through the friction-clutch for restoring the speeder-lever to its normal position.

5. In a speed-regulator for water-wheels, the combination with a water-wheel-gate controller, of a governor, a speeder-lever operated by the governor, and connections between the said controller and the speeder-lever including a friction-clutch, an operating-lever, an operating-bar between the said operating-lever and the speeder-lever, a rock-arm, and a rod operated by the said arm and operating to restore the speeder-lever to its normal position.

6. In a speed-regulator, the combination with a gate-controller, of a centrifugal governor, connections between the governor and controller, a speeder-lever operated by the governor, and connections between the controller and speeder-lever, including means for adjusting the resistance of those connections to operation by the speeder-lever.

7. In a speed-regulator, the combination with a gate-controller, of a centrifugal governor, connections between the governor and gate-controller, a speed-lever operated by the said governor, and connections between the said controller and speeder-lever, including a clutch, an operating-lever, an operating-bar connected with the speeder-lever and formed with a cam operating upon the operating-lever, and means brought into play by the friction-clutch for restoring the speeder-lever to its normal position and arresting the gate-controller.

8. In a speed-regulator, the combination with a gate-controller, of a centrifugal governor, connections between the governor and controller, a speeder-lever, connections between the gate-controller and the speeder-lever, whereby the gate-controller is arrested, and means for absorbing or nullifying the minor fluctuations of the speeder-lever or gate-controller.

9. In a speed-regulator, the combination with a gate-controller, of a centrifugal governor, connections between the governor and controller, a speeder-lever, connections between the gate-controller and the speeder-lever, whereby the gate-controller is arrested, and a tension device for nullifying the minor fluctuations of the speeder-lever, including two pins engaged with the said lever, springs coacting with the said pins, and means for varying the tension of those springs.

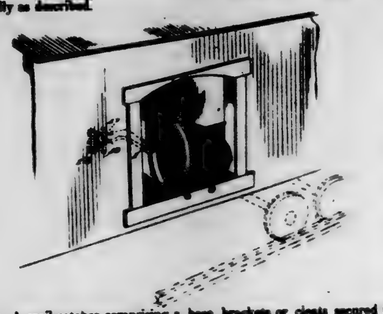
706,822. SEPARABLE RING. CLEMENT A. KELLOGG, East Carmel, Ohio. Filed Mar. 17, 1902. Serial No. 98,658. (No model.)

Claim.—1. In a separable ring the combination with relatively fixed and movable ring-sections, of a hinge-pin projecting from one of said sections, a hinge-pin socket formed in the other of said sections, and a spur folded over said pin in its socket for interlocking the ring-sections, substantially as described.

2. In a separable ring, the combination with relatively fixed and movable ring-sections, of a hinge-pin projecting from one of said sections bearing an angular feather, a socket in the other of said sections for receiving said hinge-pin, and a spur folded over the hinge-pin to prevent its withdrawal from the socket aforesaid, substantially as described.

706,823. MAIL-BAG CATCHER. GEORGE B. KLINK and JOHN C. KLINK, Tacoma, Wash. Filed Jan. 31, 1902. Serial No. 92,070. (No model.)

Claim.—1. A mail-catcher comprising a base, a bracket or cleat secured to the side of a car-door having grooves to receive said base, an abutment-wall formed on said cleat or bracket for limiting the movement of said base, an arm pivotally carried by said base, means for normally forcing the arm outwardly, and means for retaining it in position, substantially as described.

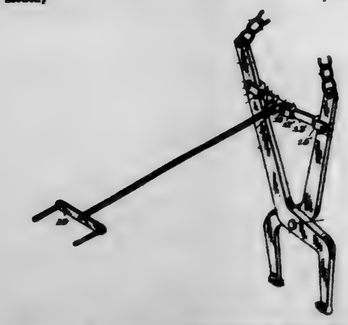


2. A mail-catcher comprising a base, brackets or cleats secured to the opposite sides of the car-door having grooves to receive the said base, abutment-walls formed on the door sides of said cleats or brackets closing the end of the recess therein for limiting the movement of said base in that direction, a pivoted arm carried by said base, means for normally forcing the arm outwardly through the door, and means for retaining it in said position, substantially as described.

3. A mail-catcher comprising a movable base, an arm pivotally mounted thereon inside a car and bent so as to project therefrom when swung to its outer position, spring means carried by said base for normally forcing the arm outwardly, a ratchet mechanism also on said base for holding the arm at various positions when it is swung inwardly, the impact of the mail-bag striking the arm, forcing it automatically inwardly where it is held by the said ratchet mechanism, substantially as described.

4. A mail-catcher comprising an arm carrying a mail-receiving bag, a spring for holding the arm normally outside a car-door, a ratchet-wheel attached to said arm, a spring-pawl engaging the same, means for lifting the pawl out of engagement with the ratchet so that the spring may force the arm outwardly the said pawl holding the ratchet-wheel when the arm is forced inwardly by the impact of the mail-pouch, and a movable base carrying all of said mechanism so that the catcher may be moved and used with equal facility on either side of a car-door, substantially as described.

706,824. **TONGS FOR HANDLING INGOTS, &c.** JOHN M. LAFFERTY, Pittsburg, Pa. Filed Oct. 15, 1901. Serial No. 78,673. (No model.)



Claim.—1. In tongs, the combination with the handles thereof, of straps connected to said handles and to each other, jaws on the side of one of said straps, and means connected to the said jaws to operate the straps in opening and closing the jaws of the tongs.

2. In tongs, the combination with the handles thereof, of straps pivoted to said handles and to each other, jaws on the side of one of said straps, and means connected to the said jaws to operate the straps in opening and closing the jaws of the tongs.

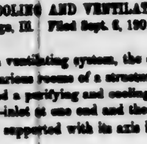
3. In tongs, the combination with the handles thereof, of straps pivoted to said handles and to each other, jaws on the side of one of said straps, stops on said handles to limit the movement of the straps, and means engaging with said jaws to operate the straps in opening and closing the jaws on the tongs.

4. In tongs, the combination with the handles thereof, of straps pivoted to said handles and to each other, jaws on the side of one of said straps, and a lever or bar connected to the said jaws to operate the straps in opening and closing the jaws of the tongs.

5. In tongs, the combination with the handles thereof, of straps pivoted to said handles and to each other, jaws on the side of one of said straps, and a lever or bar pivoted to the said jaws to operate the straps in opening and closing the jaws of the tongs.

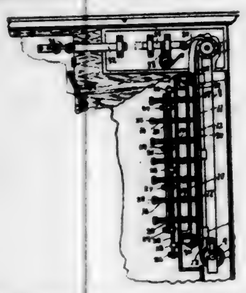
6. In tongs, the combination with the handles thereof, of straps pivoted to said handles and to each other, jaws on the side of one of said straps, a lever or bar pivoted to the said jaws, and handles on said lever or bar for moving the same and the straps to open and close the jaws of the tongs.

706,825. **NUT-LOCK.** HERBERT W. LANDMAN, Barton, Md. Filed May 26, 1902. Serial No. 108,390. (No model.)



Claim.—In a nut-lock the combination of a nut provided in its base with an approximately wedge-shaped recess the inner end of which is in communication with the nut-opening, and an aperture arranged adjacent one of the edges of the said nut, and an approximately T-shaped spring locking-lever provided on its enlarged end with an inwardly-projecting integral flange, arranged in the said recess, and provided adjacent its outer end with a projection to engage the said aperture, substantially as described.

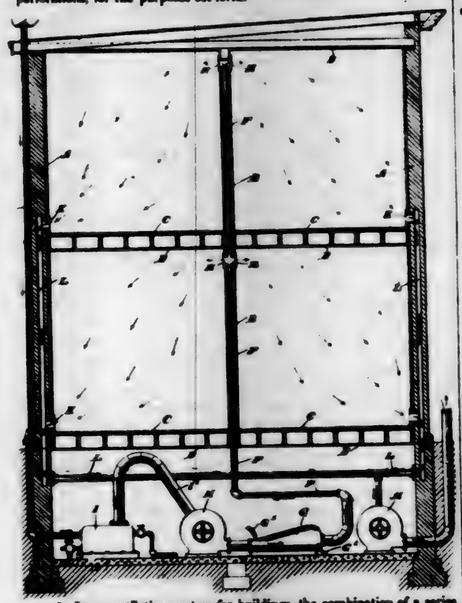
706,826. **VOTING-MACHINE.** WILLIAM LARSELL, Bay City, Mich. Filed Feb. 14, 1900. Serial No. 5,153. (No model.)



Claim.—In a voting-machine, the combination of the voting-booth provided with an entrance-door, an upper and a lower roller journaled in supports within the booth, a supporting-board extending over the space between the rollers, a tally-sheet passed over the outer face of the board and with its end portions secured upon the rollers, mechanism for imparting revolution to the rollers by the movement of the door, a removable supporting-plate arranged in front of the tally-sheet and carrying a series of plungers having on their outer printing die-faces presented to the tally-sheet, a series of springs for actuating the plungers outwardly, a curtain-shutter carried by a spring-roller at one side of the booth and located in front of the supporting-plate, a line carried by pulleys and extending across the booth and with one end secured to the said shutter and having its opposite end secured to the outer edge of the door for moving the shutter across the booth in front of the series of plungers when the door is opened, and a spring for swinging the entrance-door open, substantially as set forth.

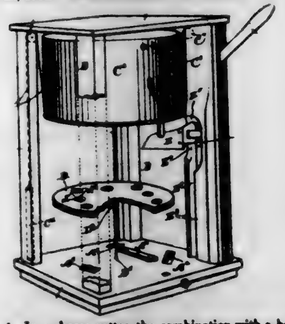
706,827. **COOLING AND VENTILATING SYSTEM.** JAMES E. LAWRENCE, Chicago, Ill. Filed Sept. 6, 1901. Serial No. 74,581. (No model.)

Claim.—1. In a ventilating system, the combination of a series of ducts leading to the various rooms of a structure, a blower for forcing air through said ducts, and a purifying and cooling apparatus consisting of a vessel having the air-inlet at one end and the air-outlet at the opposite end, and a water-coil supported with its axis in the path of the air-current, so that the air will pass through the spaces inclosed by the coil on its way through the apparatus, said coil being provided with numerous fine perforations, for the purposes set forth.



2. In a ventilating system for buildings, the combination of a series of fresh-air ducts leading to the various rooms, a cooler connected to these ducts, a blower connected to the cooler, a purifying apparatus consisting of a vessel having an air-inlet at one end and an air-outlet at the opposite end, this outlet rising vertically directly from the vessel and then extended downward to the blower, a pipe for supplying water to the vessel and means for drawing off water from the vessel, a water-coil connected to the supply-pipe and supported within the vessel above the water therein and with its axis in the path of the air-current and provided with numerous perforations throughout its length, and means for exhausting the vitiated air from the various rooms of the building, for the purposes set forth.

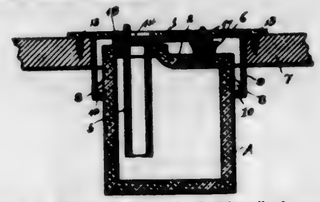
706,828. **CHEESE-CUTTER.** FRANK MAY, Knoxville, Tenn. Filed Jan. 22, 1902. Serial No. 90,104. (No model.)



Claim.—1. In a cheese-cutter, the combination with a base, a turn-table, and a vertically-shiftable cover, of a vertically-reciprocable knife supported outside of the range of said cover and adapted to be turned so as to extend radially substantially to the axial line of said turn-table and to be turned laterally out of the range of said cover, substantially as described.

2. In a cheese-cutter, the combination with a base, a turn-table, and a vertically-shiftable cover, of a knife secured to a vertically-reciprocable support outside of the range of said cover at a suitable distance from the axial line of the turn-table to permit the point of said knife to extend substantially to said axial line, suitable guides for turning said knife laterally out of the range of said cover when said knife is at the upper limit of its vertical movement and for turning said knife into the working position when it descends, substantially as described.

706,829. **INK-WELL.** JOHN P. MENTZER, Chicago, Ill., assignor to Atkinson & Mentzer, Chicago, Ill., a Firm. Filed June 28, 1901. Serial No. 66,203. (No model.)



Claim.—1. The combination with the ink-well, of an annular support for the same, the well being provided with projections and the support having a flange provided with apertures through which said projections can pass, whereby the well can be inserted into the annular support from below and then turned to cause the projections to rest upon said flange, a cover adapted to be secured in position above the well and having an aperture to permit access to the well, a stopper for opening and closing said aperture, and means on the cover for engaging the well to prevent the rotation thereof, substantially as described.

2. The combination of an annular support having notches or recesses at intervals, a well having lateral projections adapted to rest upon the annular support and to thereby support the well, the lateral projections being adapted to pass through the notches or recesses in the annular support, whereby the well can be inserted from below and then turned to cause the projections to rest upon the support, and a plate adapted to be secured in position above the well and provided with means for engaging the same to prevent rotation thereof, substantially as set forth.

3. The combination of an annular support having its inner edge provided at intervals with notches or recesses and having lateral projections adapted to rest upon the annular support and thereby support the well, said projections being adapted to pass through the notches in the support, whereby the well can be inserted in position from below and then turned to cause the projections to rest upon the support, and means for holding the well against rotation, substantially as set forth.

4. The combination with a well having lugs or projections 8, 8, of a collar 9 secured to the desk and having a flange 10 adapted to support the projections 8, 8, and provided with apertures or notches 11, 11, capable of receiving the projections 8, 8, a cover 12 secured upon the top of the desk and having an opening adapted to register with the pen-opening in the well, a stopper for opening and closing said pen-opening, and means on the cover 12 for holding the well against rotation, substantially as described.

5. The combination with a well having projections or lugs 8, 8, of a collar 9 secured to the desk and provided with a flange 10 having notches 11, 11, adapted to receive the lugs or projections 8, 8, a tube 5 extending to nearly the bottom of the well, a cork 6 fitted into an aperture in the top of the well, a cover 12 secured to the desk above the well and having an aperture registering with the tube 5, a swinging stopper adapted to open and close said opening in the cover, a cork provided for an opening in the well, and a pivot-pin for said swinging stopper adapted to rest upon said cork and thus hold the well against rotation, substantially as described.

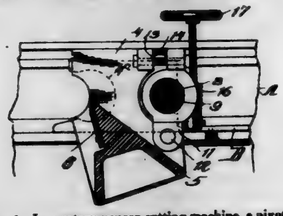
706,830. **PACKAGE FOR WATER-BOTTLES, WATER-BAGS, &c.** EDWARD E. HIMMAN, New Haven, Conn., assignor to the Stamless Rubber Co., New Haven, Conn., a Corporation. Filed Apr. 1, 1902. Serial No. 100,987. (No model.)

Claim.—1. A package for water-bottles, &c., comprising a box and a cover hinged to its upper edge at one end thereof, said cover formed

with sides adapted to overlap the sides of the box when the cover is closed, the sides of the said cover connected with the box, and a clamp secured to the inner face of the cover to support the neck of the bottle, the main portion of which rests in the box, substantially as described.

2. A package for water-bottles, &c., comprising a box, a cover hinged thereto at one end, means connecting the cover and box for supporting the cover in a raised position, the sides of said cover tapering from its forward edge rearward, a holder and a label secured to the inner face of the top of the box and connecting the holder thereto said holder adapted to support a water-bottle by its neck whereby the bottle may rest in the box and be otherwise free, substantially as described.

706,831. VENEER-CUTTING MACHINE. LOUIS G. MERRITT, Lockport, N. Y. Filed Mar. 11, 1902. Serial No. 97,714. (No model.)



Claim.—1. In a rotary veneer-cutting machine, a pivoted knife-carriage, means for automatically changing the pitch of the knife, and independent means whereby the pitch of the knife can be abruptly changed at any desired point without affecting said automatic means.

2. In a rotary veneer-cutting machine, a suitable framework, blocks slidable in ways thereon, a knife-carriage pivotally mounted on said blocks, blocks connected to said knife-carriage and traveling on fixed ways on the framework of the machine, which ways are inclined to impart through the blocks traveling thereon a change of pitch of the knife at a fixed rate as the knife is fed toward the work.

3. In a rotary veneer-cutting machine, a suitable framework, blocks slidable in ways thereon, a knife-carriage pivotally mounted on said blocks, hangers pivotally connected to said knife-carriage a shaft passing through said hangers, inclined wedges in connection with said ways, bearing-blocks for supporting the ends of said shaft movable on said wedges and means whereby said slide-blocks and said bearing-blocks may be fed together toward the work, whereby the pitch of the knife will be automatically changed during such feeding movement.

4. In a veneer-cutting machine, in combination, the frame having suitable ways A thereon, the slide-blocks 2 adapted to be fed therealong, the knife-carriage pivotally mounted on said slide-blocks, the hangers pivotally connected to said knife-carriage, the shaft passing through said hangers, the blocks 10 in which said shaft has eccentric bearings at its ends, means for rotating said shaft in order to change the pitch of the knife, the inclined ways or wedges B in connection with the main ways, upon which said bearing-blocks 10 travel, whereby the pitch of the knife is automatically changed while it is being fed toward the work.

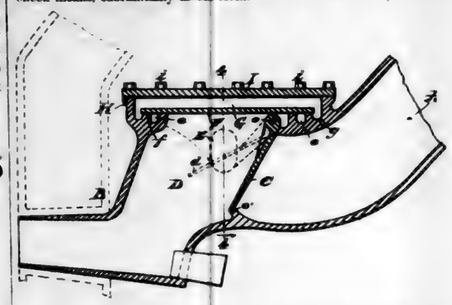
5. In combination, the frame having suitable ways thereon, the slide-blocks adapted to be fed therealong, the tool-carriage mounted on said slide-blocks, the pressure-bar casting, the second blocks providing points of support for both the pressure-bar casting and the tool-carriage, said slide-blocks being cut away so as to straddle said second blocks and permit of independent movement thereof substantially as and for the purposes set forth.

6. In a veneer-cutting machine in combination, a frame having suitable ways A thereon, the slide-blocks 2 adapted to be fed therealong, said blocks being cut away as at C, the knife-carriage pivotally mounted on said slide-blocks, the hangers pivotally connected to said knife-carriage, a shaft passing through said hangers, the pressure-bar casting supported by said shaft, the blocks 10 providing bearings for the ends of said shaft, said blocks being located within the cut-away portion of said slide-blocks 2 whereby they may be reciprocated relatively to said slide-blocks substantially as and for the purposes set forth.

706,832. FURNACE-TWYER. EDWIN H. MEREWETHER, San Luis Potosi, Mexico. Filed Nov. 30, 1901. Serial No. 83,773. (No model.)

Claim.—1. In a furnace blast apparatus an air-introducing mechanism having a furnace outlet-duct, a blast inlet-duct, an escape-duct communicating with the atmosphere, a passage-way connecting the blast inlet-duct and the furnace outlet-duct and the closing devices simultaneously closing said passage-way and the escape outlet-duct, substantially as set forth.

2. In a furnace blast apparatus an air-introducing mechanism having a furnace outlet-duct, an inlet-duct, means for checking the backflow of gas from the furnace-duct to the inlet-duct, a duct communicating with a region of pressure lower than that in either of the aforesaid ducts and a closing device for said low-pressure duct independent of the said gas-check means, substantially as set forth.



3. In a furnace blast mechanism an air-introducing mechanism having a furnace-duct, a blast-duct communicating therewith, a check-valve between the furnace-duct and the blast-duct, an atmosphere-duct adapted to communicate with the furnace-duct, a valve for the atmosphere-duct movable independently of the first aforesaid valve and adapted to be closed when the first said valve is closed, substantially as set forth.

4. The combination of the twyer duct or a tlet B, the blast or inlet duct A, the automatically-acting means for closing the duct A against backflow of gases, the escape-passage E adapted to communicate with the twyer to connect the latter with an exterior space and a second closing device for closing the escape-passage, the two said closing devices being adapted to be closed simultaneously and to be opened independently of each other, substantially as set forth.

5. In a furnace blast mechanism an air-introducing device having a main check-valve, a duct on the outside of said valve, a furnace-duct on the inner side of said valve, a supplemental escape-duct relatively on the inner side of said valve adapted to connect the furnace-duct with a region of relatively low pressure and a supplemental valve movable independently of the main check-valve for closing the escape-duct, substantially as set forth.

6. In a furnace blast mechanism an air-introducing device having a check-valve, an inlet-duct on the outer side of said valve, an outlet-duct on the inner side of said valve, an escape-duct adapted to connect said inlet-duct with a region of relatively low pressure, a supplemental valve held closed by the pressure in the inlet-duct and interposed between the outlet-duct and the escape-duct, substantially as set forth.

7. In a furnace blast apparatus an air-introducing mechanism having a furnace outlet-duct, a blast inlet-duct, two passage-ways from the inlet-duct to the furnace outlet-duct, two closing devices, one for each of said passage-ways, and a supplemental outlet-duct adapted to communicate with the furnace outlet-duct, said supplemental outlet being closed by one of said closing devices, substantially as set forth.

8. In a furnace blast apparatus an air-introducing mechanism having a furnace outlet-duct, a blast inlet-duct, two passage-ways from the inlet-duct to the furnace outlet-duct, two closing devices, one for each of said passage-ways, and a supplemental outlet-duct adapted to communicate both with the aforesaid outlet-duct and with the inlet-duct, said supplemental outlet-duct being closed by one of the said closing devices, substantially as set forth.

9. In a furnace blast apparatus the air-introducing mechanism having a chamber D, three ducts adapted to communicate with said chamber, the first duct also communicating with an air-forcing mechanism, the second duct communicating with the interior of a furnace, and the third duct communicating with the open atmosphere, and two independent valves, one interposed between said chamber and the open atmosphere-duct, and one interposed between the said chamber and the blast-duct, and one being held open and the other held closed independently of each other by the air-blast, substantially as set forth.

10. In a furnace blast mechanism an air-introducing device having an inlet, a furnace-outlet, a check-valve between the inlet and the outlet, a supplemental outlet connecting the furnace-outlet with a region of pressure lower than that of the air-blast, a valve between said two outlets and a duct supplemental to the check-valve passage to carry air from the inlet to the second valve to hold it closed.

11. In a furnace blast mechanism an air-introducing device having a check-valve, a duct on the outer side of the valve, a furnace-duct on the inner side of the valve, a duct adapted to connect the furnace-duct with the open atmosphere, a valve for said duct supplemental to and independent of the check-valve, a pressure-chamber on the outer side of the supplemental valve and a duct adapted to connect said pressure-chamber with a region of relatively high pressure, substantially as set forth.

12. In a furnace blast mechanism an air-introducing device having a check-valve, an inlet-duct on the outer side of said valve, a furnace-duct on the inner side of said valve, an escape-duct adapted to connect the furnace-duct with the open atmosphere, a valve supplemental to the check-valve for closing said escape-duct, a pressure-chamber for the supplemental valve and a reduced port connecting said pressure-chamber with the first aforesaid duct on the outer side of the check-valve, substantially as set forth.

13. In furnace blast apparatus the air-introducing mechanism having a chamber as at D, three ducts, the first adapted to communicate with said chamber, the second being a furnace-duct permanently communicating therewith, and the third being an atmosphere-duct intermittently communicating therewith, a gravity-valve introduced between the first duct and said chamber D and adapted to be opened by the air-blast, a gravity-valve interposed between the said chamber and the atmosphere-duct and normally held closed by the blast, substantially as set forth.

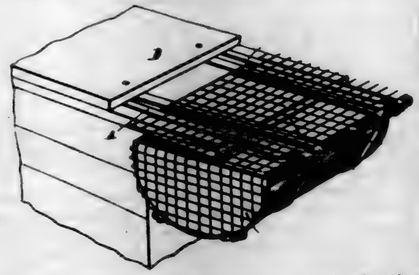
14. The combination of the twyer, the blast-duct, an automatically-operative check-valve between the same, a relief device communicating with the twyer, and means whereby the operation of said relief device is determined by a difference of pressure in said blast-duct and twyer when cut off from each other by said check-valve.

15. The combination of the twyer, the blast-duct, an escape-duct from the twyer, means whereby said escape-duct is closed by the pressure of the blast, and an automatically-acting check-valve between the twyer and blast-duct.

16. The combination of the twyer, the blast-duct, an automatically-acting check-valve between the same, an escape-duct, passages from each side of the check-valve communicating with said escape-duct, and a supplemental valve acting to close the passage from the twyer and from the blast-duct to the escape-duct.

17. The combination of the twyer, the blast-duct, an automatically-acting check-valve between the same, an escape-passage from the twyer to an outer region of relatively low pressure, a supplemental valve controlling said escape-passage, and means whereby the pressure in the blast-duct acts on said supplemental valve in the direction in which the same closes.

706,833. EAVES-TROUGH PROTECTOR. WILLIAM L. MEYER, Anson, Kans. Filed Nov. 13, 1901. Serial No. 82,133. (No model.)

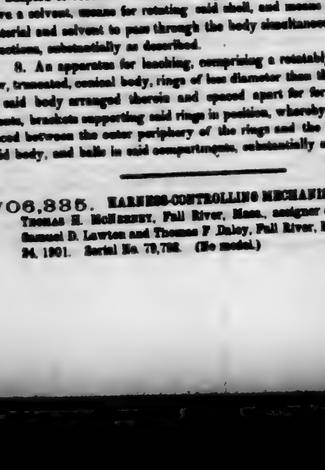


Claim.—In an eave-trough protector the combination of a strip of wire-cloth, slightly wider than the eave-trough to which it is to be applied, a clamp A one end of which clamps the lower edge of the cloth to the headed edge of the trough and the other end is secured to the roof and clamps the upper edge of the cloth thereto, a supplemental clamp B applied to the lower edge of the cloth and the headed edge of the trough and a piece of flexible wire fastening the strip of cloth about the end of the trough, substantially as set forth.

706,834. APPARATUS FOR LEACHING ORES, &c. GEORGE MOORE, Salt Lake City, Utah. Filed Feb. 3, 1902. Serial No. 92,262. (No model.)

Claim.—1. An apparatus for leaching comprising a shell or body in the form of a truncated cone, a head at each end of said body having a central opening, one of said openings to receive material to be operated upon and the other to receive a fluid solvent, means for rotating the body about its central horizontal axial line, and means for causing the material and fluid solvent to pass through the body simultaneously in opposite directions, substantially as described.

2. An apparatus for leaching comprising a shell or body in the form of a truncated cone, a head at each end of said body having a central opening, one of said openings to receive material to be operated upon, and the other to receive a fluid solvent, means for rotating the body about its central horizontal axial line, and combined means for actuating the material through the body in one direction, and disintegrating it during its passage, and means for simultaneously causing the fluid solvent to flow through the body in the opposite direction to the movement of the material, substantially as described.



3. An apparatus for leaching, comprising a shell or body in the form of a truncated cone mounted to rotate about its central horizontal axial line, a head at each end having a central opening, the opening in the larger head being arranged to receive a fluid solvent, and that in the smaller head to receive material to be operated upon, means for actuating the material to be operated upon through the body from the smaller to the larger end, and means for causing the fluid solvent to flow through the body from the larger to the smaller end, substantially as described.

4. An apparatus for leaching, comprising a shell or body in the form of a truncated cone, a head at each end having a central opening, the opening of the small head being larger than that of the large head, and adapted to receive material to be operated upon, means for admitting a fluid solvent through the opening in the large head, and discharging it through the opening in the small head, and means for actuating the material through the body, and discharging through the opening of the large head, substantially as described.

5. An apparatus for leaching, comprising a hollow truncated conical body or shell arranged to rotate about its central horizontal axial line, brackets secured in the shell at intervals of its length, transverse rings secured upon said brackets, out of contact with the shell, and forming partitions to divide the shell into compartments, and a series of balls in each compartment, substantially as described.

6. An apparatus for leaching, comprising a hollow truncated, conical body, a head at the smaller end, having a central opening to receive the material to be operated upon, a head at the larger end having a central opening, a pipe for discharging fluid solvent into the latter opening, a guard or cover over said pipe, and means for discharging the material admitted at the small end through the large end around said guard, substantially as described.

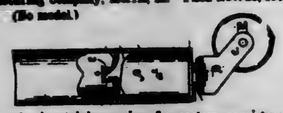
7. An apparatus for leaching comprising a suitable shell, a head at each end of said shell, having a central opening, one of said openings being adapted to receive material to be operated upon and the other to receive a solvent, means for rotating said shell, and means for causing the material and solvent to pass through the body simultaneously in opposite directions, substantially as described.

8. An apparatus for leaching, comprising a rotatably-mounted hollow, truncated, conical body, rings of less diameter than the inner surface of said body arranged therein and spaced apart for forming compartments, brackets supporting said rings in position, whereby spaces are produced between the outer periphery of the rings and the inner surface of said body, and balls in said compartments, substantially as described.

706,835. HARNESS-CONTROLLING MECHANISM FOR LOOMS. THOMAS H. MOLLINEUX, Fall River, Mass., assignor of two-thirds to Samuel D. Lawton and Thomas F. Daley, Fall River, Mass. Filed Oct. 24, 1901. Serial No. 79,782. (No model.)

Claim.—In a loom harness mechanism, a plurality of vertically-moving harness-frames, guides mounted above said frames, a support and an equalizer comprising a pair of axially-alined connected primary rolls or cylinders stationarily journaled on said support in a position laterally remote from the guides, primary flexible bands wrapped around the respective rolls in opposite directions, one or more of said bands being looped to form journal-bearings, secondary pairs of axially-alined connected rolls or cylinders having journals mounted to rotate in the said bearing-loops, secondary pairs of flexible bands wrapped in opposite directions around said secondary rolls, and suspending connections between said primary and secondary bands and the harness-frames passing over said guides.

706,886. CASTER. DAVID EISEN, Morris, Ill., assignor to Hintzl Manufacturing Company, Morris, Ill. Filed Nov. 23, 1901. Serial No. 83,344. (No model.)



Claim.—1. A retaining-spring for casters, consisting of a tubular body formed from a plate of springy material to have one end of the plate overlap the outer wall of the body and freely contact therewith, a sleeve within the body, and a web between the wall and the sleeve, substantially as described.

2. A retaining-spring for casters made from a single plate of springy material, consisting of a tubular body formed to have one end of the plate overlap the outer wall of the body and freely contact therewith, a sleeve within the body, and a web between the wall and the sleeve, substantially as described.

3. A retaining-spring for casters made from a single plate of springy material spirally bent or coiled to form a sleeve and further bent or coiled in the same direction to form a wall or body, and a web between the sleeve and the wall or body with the outer end of the plate free to allow of compression, substantially as described.

4. A retaining-spring for casters made from a single plate of springy material bent or coiled to form a sleeve and further bent or coiled to form a wall or body provided with a step on its upper edge bent inward toward the sleeve, and a web between the sleeve and the wall or body with the outer end of the plate free to allow of compression, substantially as described.

5. A retaining-spring for casters made from a single plate of springy material bent or coiled to form a sleeve and further bent or coiled to form a wall or body, and a web between the sleeve and the wall or body provided in its lower edge with a recess the outer end of the plate being free to allow of compression, substantially a described.

6. A retaining-spring for casters made from a single plate of springy material bent or coiled to form a sleeve and further bent or coiled to form a wall or body provided with steps bent inward toward the sleeve, and a web between the sleeve and the wall or body provided in its edge with a recess the outer end of the plate being free to allow of compression, substantially as described.

7. The combination of a retaining-spring for casters made from a single plate of springy material bent or coiled to form a sleeve and further bent or coiled to form a wall or body, a web between the sleeve and the wall or body, provided in its edge with a recess the outer end of the plate being free to allow of compression, and a distending-washer encircling the sleeve and lying within the recess in the web, substantially as described.

8. In combination with a caster, of a retaining-spring therefor made from a single piece of springy material bent or coiled to form a sleeve and further bent or coiled to form a wall or body having its outer free edge curved or rounded at its upper corner, a web between the sleeve and the wall or body provided in its edge with a recess, a distending-washer encircling the sleeve and lying within the recess in the web, and a plate carrying a roller and journaled within the sleeve, substantially as described.

9. In combination with a caster, of a retaining-spring therefor made from a single piece of springy material bent or coiled to form a sleeve and further bent or coiled to form a wall or body, a web between the sleeve and the wall or body provided in its edge with a recess, a distending-washer encircling the sleeve and lying within the recess in the web, a plate carrying a roller and journaled within the sleeve, and an exterior washer encircling the plate and lying outside of the retaining-spring, substantially as described.

10. An essentially oblong blank for the formation of a retaining-spring for casters with one end of greater width than the other having a recess in its lower edge and having, in its upper edge near the wider end, a cut allowing a portion of its upper edge to be turned inwardly and furnish a stop or abutment when the blank is formed into a sleeve and spring, substantially as described.

11. A blank for the formation of a retaining-spring for casters oblong in general outline having the upper edge of one of its ends curved or rounded and having a recess in its lower edge and having two cuts on its upper edge adapted to be inwardly turned furnishing stops or abutments when the blank is formed into a sleeve and spring, substantially as described.

706,887. CASTER. DAVID EISEN and PETER B. PETERSEN, Morris, Ill., assignors to Hintzl Manufacturing Company, Morris, Ill. Filed Dec. 20, 1901. Serial No. 86,671. (No model.)

Claim.—1. A retainer or retaining-socket for casters consisting of a split tubular body of springy material provided at its upper end with a wing or ear extending onto the tubular body and crossing the slit therein, substantially as described.

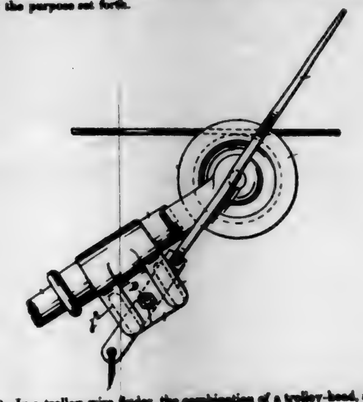
2. A retainer or retaining-socket for casters consisting of a split tubular body of springy material provided at its upper end with two wings or ears extending onto the tubular body, crossing the slot therein and overlapping one another to increase the spring action of the socket, substantially as described.

3. A retainer or retaining-socket for casters consisting of a split tubular body of springy material provided at its upper end with two wings or ears extending onto the tubular body, crossing the slot therein and overlapping one another to increase the spring action of the socket, and a base-disk centrally and firmly attached to the lower end of the tubular body, in combination with a plate carrying a caster-wheel provided at its upper end with a head adapted to be forced through the socket and project above the wings and upper edge thereof, substantially as described.

4. A retainer or retaining-spring for casters consisting of a split tubular body of springy material provided at its upper end with two wings or ears extending onto the tubular body crossing the slit therein and overlapping one another to increase the spring action of the socket, in combination with a plate carrying a caster-wheel and provided with a head adapted to be forced through the spring-socket expanding the same and to project beyond and rest upon the upper edge of the wings and the socket and further provided with a collar near its lower end for contact with the lower end of the socket, substantially as described.

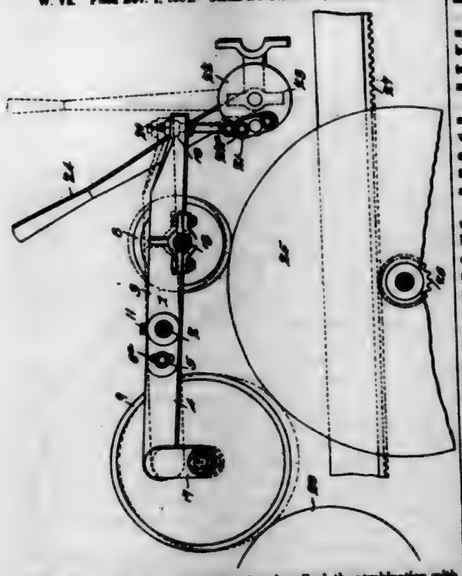
706,888. TROLLEY-WIRE-FINDER. LOUIS C. HOLAN, St. Paul, Minn. Filed Apr. 11, 1902. Serial No. 102,491. (No model.)

Claim.—1. In a trolley-wire finder, the combination of a trolley-head, a trolley-wheel carried by said head, an elongated band divided longitudinally and with elongated plates depending therefrom contiguous to said longitudinal division, inwardly-projecting ribs upon said plates near their ends, a transverse bolt engaging said plates, and a wire-finder consisting of a central bar pivoted upon said bolt between said plates and with its ends extending beyond the ends of the plates and between said ribs, and with diverging extended forks adapted to guide the wire to the groove of the trolley-wheel when said finder is actuated, substantially as and for the purpose set forth.



2. In a trolley-wire finder, the combination of a trolley-head, a trolley-wheel carried by said head, an elongated band divided longitudinally and with elongated plates depending therefrom contiguous to said longitudinal division, inwardly-projecting ribs upon said plates near their ends, a bolt passing transversely through said plates centrally thereof and with spaced shoulders thereon between said plates, nuts on the ends of said bolt outside said plates, and a wire-finder consisting of a central bar pivoted upon said bolt between said plates and with its ends extending beyond their ends, and between said ribs, and with diverging forks adapted to guide the trolley-wire to the trolley-wheel, substantially as set forth.

706,889. SAWMILL-FEED. ALEXANDER C. GREEN, Charleston, W. Va. Filed Nov. 1, 1901. Serial No. 80,772. (No model.)



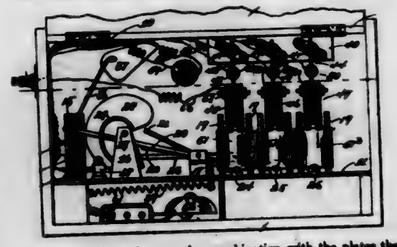
Claim.—1. In a device of the class described, the combination with pulleys 25 and 26 of an oscillatory frame pivotally mounted between its ends and composed of sections adjustably connected together, wheels mounted on the sections of the frame and carried by the latter, and means for operating the frame, substantially as described.

2. In a device of the class described, the combination with pulleys 25 and 26 of a shaft, an oscillatory frame composed of sections having alined openings to receive the shaft and adjustably connected together, wheels mounted on the frame and located at opposite sides of the shaft, and means for operating the frame, substantially as described.

3. In a device of the class described, the combination with pulleys 25 and 26 of a shaft, an oscillatory frame mounted on the shaft and extending from the same in opposite directions, a feed-wheel mounted on the frame at one side of the shaft, links depending from the frame and arranged at opposite sides of the shaft, a wheel supported by the lower ends of said links, and means for operating the frame, substantially as described.

4. In a device of the class described, the combination with pulleys 25 and 26 of the vertically-adjustable bearings, a shaft mounted thereon, a frame mounted on the shaft and extending from the same in opposite directions, a pair of links supported by the frame and pivotally connected with the same, a friction-wheel supported by the links, a feed-wheel mounted on the frame, and operating mechanism connected with the frame, substantially as described.

706,840. BATTERY. WILLIAM L. PARKHOFF, New Haven, Conn. Filed Mar. 18, 1902. Serial No. 98,321. (No model.)



Claim.—1. In a battery the combination with the plates thereof; of a cell; a rest upon which said cell is adapted to stand so that the mouth thereof will be under said plates and in a line therewith; an elevating-lever one end of which is secured to said rest; and means for operating the other end of said lever so that said cell may be raised to contain said plates, substantially as described.

2. In a battery the combination with a series of plates; of cells; rests upon which said cells are adapted to stand so that the mouths thereof will be under said plates and in a line therewith; an elevating-lever secured to each of said rests; and means for raising said levers so that said cells may be raised to contain said series of plates, substantially as described.

3. In a battery the combination with the plates thereof; of a cell; a rest upon which said cell is adapted to stand so that the mouth thereof will be under said plates and in a line therewith; an elevating-lever secured to said rest; a cam adapted to come in contact, upon the revolution thereof, with said lever to force said cell upward to contain said plates; and means for operating said cam, substantially as described.

4. In a battery the combination with a series of plates; of cells; rests upon which said cells are adapted to stand so that the mouths thereof will be under said plates and in a line therewith; elevating-levers secured to each of said rests; cams adapted to come in contact with said levers upon the revolution thereof to force said cells upward to contain said plates; and means for operating said cams, substantially as described.

5. In a battery, the combination with the plates thereof, of a cell; a rest upon which said cell is adapted to stand so that the mouth thereof will be under said plates and in a line therewith; an elevating-lever secured to said rest; a contact-plate; a contact-lever; connection between said battery and said contact-plate; connection between said contact-plate and said contact-lever; and means for elevating said rest and said cell, and forcing said contact-lever into connection with said contact-plate, substantially as described.

6. In a battery the combination with a series of plates; of cells; rests upon which said cells are adapted to stand so that the mouths thereof will be under said plates and in a line therewith; elevating-levers secured to said rests; a contact-plate; a contact-lever; connection between said battery and said contact-plate; connection between said contact-plate and said contact-lever; and means for elevating said rests and said cells, and forcing said contact-lever into connection with said contact-plate, substantially as described.

7. In a battery the combination with the plates thereof; of a cell; a

rest upon which said cell is adapted to stand so that the mouth thereof will be under said plates and in a line therewith; an elevating-lever secured to said rest; a contact-plate; a contact-lever; a cam adapted to come in contact with said elevating-lever and said contact-lever, to force said cell upward to contain said plates, and said contact-lever into contact with said contact-plate, and means for operating said cam, substantially as described.

8. In a battery the combination with a series of plates; of cells; rests upon which said cells are adapted to stand so that the mouths thereof will be under said plates and in a line therewith; elevating-levers secured to said rests; a contact-plate; a contact-lever; cams adapted to come in contact with said elevating-levers and said contact-lever, to force said cells upward to contain said plates, and said contact-lever into contact with said contact-plate, and means for operating said cams, substantially as described.

9. In a battery the combination with a casing containing therein a shelf; battery-plates; a cell; a standard secured to said shelf; an elevating-lever pivoted in said standard; a rest secured to one end of said lever upon which said cell is adapted to stand so that the mouth thereof will be under said plates and in a line therewith; a second standard secured to said shelf; a cam journaled in said second standard, adapted to come in contact with the other end of said lever to elevate said cell; and a handle adapted to operate said cam from the outer side of said casing, substantially as described.

10. In a battery the combination with a casing containing therein a shelf; battery-plates; cells; a standard secured to said shelf; elevating-levers pivoted in said standard; rests secured to one end of said levers upon which said cells are adapted to stand so that the mouths thereof will be under said plates and in a line therewith; a second standard secured to said shelf; cams journaled in said second standard, adapted to come in contact with the other end of said levers to elevate said cells; and a handle adapted to operate said cams from the outer side of said casing, substantially as described.

11. In a battery the combination with a casing containing therein a shelf; battery-plates; a cell; a standard secured to said shelf; an elevating-lever pivoted in said standard; a rest secured to one end of said elevating-lever upon which said cell is adapted to stand; a contact-lever pivoted in said standard; a contact-plate secured to said shelf; a second standard secured to said shelf; a cam or cams journaled in said second standard; a handle adapted to operate said cam or cams to come in contact with said elevating-lever to raise said cell in a position to contain said plates, and to force said contact-lever in connection with said contact-plate, substantially as described.

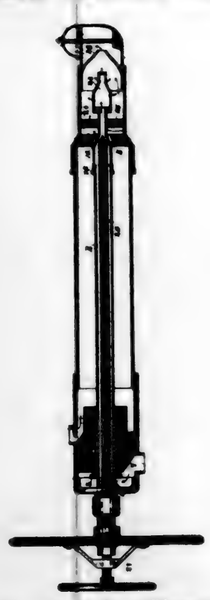
12. In a battery the combination with a casing containing therein a shelf; battery-plates; cells; guides for said cells; a standard secured to said shelf; elevating-levers pivoted in said standard; rests secured to one end of said levers upon which said cells are adapted to stand; a contact-lever pivoted in said standard; a contact-plate secured to said shelf; a second standard secured to said shelf; a cam or cams journaled in said second standard; a handle adapted to operate said cam or cams to come in contact with said elevating-levers to raise said cells in a position to contain said plates, and to force said contact-lever in connection with said contact-plate, substantially as described.

13. In a battery the combination with a casing containing therein a shelf; battery-plates; a cell; a standard secured to said shelf; an elevating-lever pivoted in said standard; a rest secured to one end of said lever upon which said cell is adapted to stand; a second standard secured to said shelf; a cam or cams journaled in said second standard, adapted to come in contact with the other end of said elevating-lever to elevate said cell; a contact-plate secured to said shelf; a contact-lever pivoted in said first-mentioned standard, adapted to be forced into connection with said contact-plate by said cam or cams; a rod one end of which is secured to the upper end of said contact-lever; a plate secured to the other end of said rod having on its inner surface denoting characters, adapted to pass before a perforation in said casing upon the operation of said contact-lever; substantially as described.

14. In a battery the combination with a casing containing therein a shelf; battery-plates; a cell; a standard secured to said shelf; an elevating-lever pivoted in said standard; a rest secured to one end of said lever upon which said cell is adapted to stand; a second standard secured to said shelf; a cam or cams journaled in said second standard, adapted to come in contact with the other end of said elevating-lever to elevate said cell; a contact-plate secured to said shelf; a contact-lever pivoted in said first-mentioned standard, adapted to be forced into connection with said contact-plate by said cam or cams; a rod one end of which is secured to the upper end of said contact-lever; a plate secured to the other end of said rod having on its inner surface denoting characters, adapted to pass before a perforation in said casing upon the operation of said contact-lever; a bell within said casing; a push-button on the outer side of said casing connecting with said bell, substantially as described.

15. In a battery the combination with a casing containing therein a shelf; battery-plates; a cell; a standard secured to said shelf; an elevating-lever pivoted in said standard; a rest secured to one end of said lever upon which said cell is adapted to stand; a second standard secured to said shelf; a cam or cams journaled in said second standard adapted to come in contact with the other end of said elevating-lever to elevate said cell; a contact-plate secured to said shelf; a contact-lever pivoted in said first-mentioned standard, adapted to be forced into connection with said contact-plate by said cam or cams; a rod one end of which is secured to the upper end of said contact-lever; a plate secured to the other end of said rod having on its inner surface denoting characters, adapted to pass before a perforation in said casing upon the operation of said contact-lever; a bell within said casing; a push-button on the outer side of said casing; binding-posts secured to the outer side of said casing, and conducting connection between said plates, contact-plate, contact-lever, push-button, bell, and binding-posts, substantially as described.

706,341. OIL-BURNER. LOUIS A. PFEIFFER and LYMAN D. STAPLES, San Francisco, Cal. Filed Nov. 13, 1901. Serial No. 82,135. (No model.)



Claim.—1. The combination in an oil-burner of concentric tubes forming a steam-space, with an inlet at one end and a convergent discharge at the other, a core forming an annular space between itself and the inner tube said inner tube having the rear end connecting with the oil-inlet and the front forming a convergent discharge within and concentric with the steam-discharge, a mixing-chamber to receive the discharge from both tubes said inner tube having an extension beyond its convergent discharge and entering the mixing-chamber, and a perforated diaphragm between the mixing-chamber and the said convergent passages and adjustable toward and from said passages, and a burner connecting with the mixing-chamber.

2. The combination in an oil-burner of concentric tubes, a block consisting of a single casting having its body formed with steam and oil passages and having a projecting flange to which the rear end of the outer tube is screwed, said block having, also a central passage and stuffing-box through which the inner tube is movable; a cap fitting a rear flange of the block and forming a chamber at the rear of the block, said chamber communicating with the oil-passage in the block and said inner tube having perforations connecting with the oil-chamber, a block with which the front ends of the tubes are connected, a mixing-chamber into which the steam and oil are delivered at the front, discharge-openings and a burner inclosing the mixing-chamber.

3. The combination in an oil-burner of concentric tubes and interior cylindrical core having an annular space between it and the outer tube, a block consisting of a single casting formed integral with oil and steam passages and forwardly and rearwardly extending flanges, said outer tube connecting with one of said flanges and a cap fitted to the other flange and forming an oil-chamber between itself and the block said block having a passage through it for the inner tube and said inner tube having perforations connecting with said chamber, a stuffing-box carried by the block and through which the inner tube passes, a second block at the front of the tubes, having projecting flanges at both ends, to one of which flanges the front end of the outer tube is fitted, said second block having a convergent passage between itself and a corresponding front portion of the inner tube, a core movable within the inner tube said inner tube extended beyond the second block, a mixing-chamber on the extension of the inner tube, an adjustable and perforated diaphragm between the mixing-chamber and the second block, and a burner connecting with the mixing-chamber.

4. In an oil-burner, the combination of inner and outer tubes, front and rear block to which the tubes are fitted, each of said blocks consisting of a single casting having front and rear extending flanges and one of said blocks having self-contained oil and steam passages, a cap fitted to the rear flange of the rear block and forming an oil-chamber communicating with said oil-passage, and said inner tube having perforations connecting with said chamber, a core passing through the inner tube means for operating the core and inner tube independently, means forming independent, convergent steam and oil passages at the front of the tube, a mixing-chamber in front of the tube and connecting with the inner tube, an adjustable perforated diaphragm between said chamber and the forward block, and a burner.

5. The combination in an oil-burner of an outer tubular chamber with blocks at opposite ends, an inner tubular chamber and a core concentric therewith, a mixing-chamber at the front with a perforated adjustable diaphragm in the rear, said diaphragm having a screw-threaded central opening through which the extension of the main inner tube is guided and movable.

6. The combination in an oil-burner of concentric tubes having blocks at opposite ends and forming outer and inner chambers, a steam-passage opening through the rear block into the outer chamber and an oil-passage leading into the inner chamber, a cone-shaped opening in the front block, a corresponding cone-shaped portion at the front of the inner tube, a guide and means for advancing and retracting the inner tube to vary the steam-passage exterior to itself, a cone-headed core adjustable within the inner tube and the cone-shaped portion of the inner tube to vary the oil-passage, a burner-chamber with an adjustable diaphragm forming a supplemental steam-chamber with openings to admit steam to the burner-chamber, and a perforated head from which oil is delivered to meet the steam in said chamber.

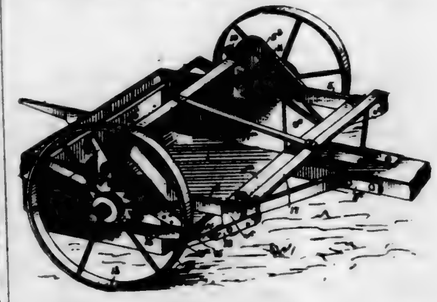
706,342. HAND-TRAP. JOHN C. POSTENFIELD, Columbus, Ohio, assignor to Harry E. Mitchell, London, Ohio. Filed Apr. 6, 1901. Serial No. 54,596. (No model.)

Claim.—1. In a hand-trap, the combination with a frame-bar 1 having a handhold enlargement 3 in its forward portion and a downturned rear end portion, a spring-actuated catch-bar pivotally connected with said bar 1, an operating-lever for said catch-bar and a rearwardly-extending trigger-rod connected with said operating-lever, of a carrier-arm having at one end means for holding removably a target and a spring connecting its remaining end with a pin in the rear portion of the bar 1, substantially as specified.

2. In a hand-trap, the combination with a frame-bar having a hand hold enlargement in its forward portion and a downturned rear end portion, and a rearwardly-extending trigger adjacent to the downturned rear end portion, of a spring-actuated carrier-arm having at one end means for holding removably a target, said carrier-arm being adapted to be released by the trigger.

3. In a hand-trap, the combination with a frame-bar having a hand-hold enlargement in its forward portion and a downturned rear end portion forming a grip for the other hand, and a spring-actuated trigger adjacent to the downturned end portion, of a spring-actuated carrier-arm having at one end means for holding removably a target, said carrier-arm being adapted to be released by said trigger.

706,848. WHEELED SCRAPER. THOMAS D. RADCLIFFE, Lawrence, Kans., assignor of one-third to Charles Rich Metcalf, Lawrence, Kans. Filed Nov. 12, 1901. Serial No. 82,094. (No model.)



Claim.—1. A wheeled scraper, comprising a pan, an end-gate therefor, having side arms straddling the pan, and pivotally secured to the pan sides; stub-axles projected from said arms at a point forward of their pivotal connection, wheels loosely mounted on the said axles; a draft-tongue, and means for locking the pivotal connections of the side arms with the wheels, whereby to elevate the pan as the wheels rotate forward, for the purpose described.

2. A wheeled scraper, comprising in combination, a pan, an end-gate closable over the front of the pan, said end-gate including side arms adapted to straddle the pan, and pivotally secured to said pan, stub-axles projected from the said side arms at a point in advance of their pivotal connection, wheels loosely mounted on said axle, and devices for connecting the pivotal connections with the wheels at a point forward of the center of the pan, whereby to lift the pan and simultaneously lower the end-gate as the wheels are drawn forward, substantially as described.

3. A wheeled scraper, comprising in combination with the supporting-wheels, the vertically-movable pan and independently-movable end-gate, a twin-hook latch mechanism for automatically engaging the pan and end-gate as they come together to hold the pan elevated and the end-gate closed for transportation, and means for tripping said twin-hook latch mechanism, for the purpose described.

4. A wheeled scraper, having a vertically-movable pan and a downwardly-closing end-gate, and mechanism controlled by the forward movement of the wheels for effecting the lifting action of the pan and closure of end-gate; of detent devices for automatically engaging the pan and the end-gate to hold them to their cooperative position, and means including a handle extended back over the pan for releasing said detent devices, substantially as shown and for the purposes described.

5. The combination with the stub-axles and the wheels, said stub-axles having rearwardly-extending frame-pieces fixedly connected thereto; of the pan, connections for pivotally supporting the pan on the frame-pieces, and means for locking the said pivotal connections with the wheels, substantially as shown and for the purpose described.

6. The combination with the stub-axles, having rearwardly-extending portions, and the wheels; of the pan, connections for pivotally supporting the pan on the end of said extending portions, means for interlocking the said pivotal connections with the wheels, and detent devices including hand-operated tripping-lever for engaging the pan and holding it to its elevated position, as specified.

7. The combination with the stub-axles, the frame-pieces extended rearwardly therefrom, and the wheels loosely mounted on the axles, and having ratchet-disk portions; of the pan pivotally supported on the axle frame-pieces, latches pivotally supported on the pan, and lever devices including a handle member for throwing said latches into engagement with the ratchet-disks on the wheel, substantially for the purposes described.

8. The combination with the stub-axles, the supporting-wheels loosely mounted thereon, frame-pieces fixedly connected to the axle and extended rearwardly of the pan pivotally suspended from said frame-pieces, means joining the pan with the wheels to lift it, said pan having forwardly-projecting latch-hooks, the draft-tongue pivotally connected to the pan, pivoted latches on said tongue for engaging the pan latch-hooks when the pan is elevated, and means for releasing the draft tongue-supported latch-hooks, substantially as shown described.

9. The combination of the pan, the end-gate having side arms straddling the pan, the draft-tongue having side arms to straddle the pan, a pivoted latch member at each side of the pan, a single pivot-pin on each side of the pan, forming a fulcrum for the ends of the end-gate and tongue side arms, and the latches at each side, stub-axles projected from the end-gate side arms at a point forward of the pan pivot-pins, the carrier-wheels loosely mounted thereon, ratchet-disks fixedly held on the wheels in a plane with the pivoted latches, means controlled from the rear of the pan for shifting said latches into engagement with the ratchet-disks, and hand-lever-released detents for automatically engaging the pan and end-gate to hold said pan and end-gate to their cooperating positions, for the purposes specified.

706,844. TOOL FOR FORMING BOTTLE-NECKS. EDWARD D. SMITH, Baltimore, Md., assignor, by mesne assignments, to Universal Seal and Stopper Company, Baltimore, Md., and Camden, N. J., a Corporation of New Jersey. Filed Jan. 7, 1902. Serial No. 89,733. (No model.)

Claim.—1. In a tool for forming bottle-necks, the combination with movable jaws and a central core, of levers connected to the core and jaws, links pivoted in advance of the lever ends and also to said lever ends, thus in conjunction with said ends forming a compound forming device adapted to be projected into operative position and retracted therefrom by the movement of the jaws, substantially as and for the purpose set forth.

2. In a tool for forming bottle-necks, the combination with a central core, of jaws connected to said core, levers rockably secured to the core and having connection with the jaws, said levers having ends constituting a part of the forming means, links pivoted to the core and to the ends of said levers and constituting the other part of the forming means, substantially as set forth.

3. In a tool for forming bottle-necks, the combination with a central core, of jaws connected to said core by links, levers pivoted to the core and to the jaws, whereby the jaws in their opening and closing movements are maintained parallel to the core and to each other, said levers having ends constituting a part of the forming device, links pivoted to the core and to the ends of said levers, and constituting the other part of the forming device, substantially as set forth.

4. In a tool for forming bottle-necks, the combination with a central core having a slot therein, of jaws connected with said core by links, levers pivoted in said slot and to the jaws, the ends of said levers constituting a part of the forming means, links pivoted in said slot in advance of the ends of said levers and pivoted to the ends thereof and constituting the other part of the forming means, substantially as set forth.

5. In a bottle-neck-forming tool, the combination with a central core having a slot therein near its forward end, jaws connected with said core and means for holding them normally separated, a stop on the core and having a forward extension, levers pivoted in the slot and to the jaws, the ends of said levers constituting a part of the forming means, links pivoted in the slot in advance of the lever ends and pivoted thereto and constituting the other part of the forming means, substantially as described.

6. In a tool for forming bottle-necks, the combination with a slotted central core, of jaws connected with said core, means for normally separating said jaws, a stop on said core having a forward extension adapted to enter the bottle-neck, levers pivoted to the core and to the jaws and having their ends shaped to constitute part of the forming device and working in said extension, links pivoted in the slot and having elongated slots in their rear ends, pins passing through the ends of the levers and the slots in the links, whereby when the jaws are closed the forming means on said links will be projected beyond the forward extension both laterally and longitudinally, substantially as described.

7. In a tool for forming bottle-necks, the combination with a central core having an enlargement near its forward end of jaws movable to and from said core for the purpose set forth, levers connected with the jaws and core, a forming device constituted in part by the lever ends, links having connection with the core and with the lever ends and constituting a part of the forming device, forming-device on the links being adapted to be projected beyond the enlargement both laterally and longitudinally when the jaws are moved toward each other, substantially as described.

8. In a tool for forming bottle-necks, the combination with a central core having an enlargement near its forward end and a stop or shoulder 6, of jaws connected with said core, a forming device mounted in said core formed in part by levers pivoted to the core and having connections with the jaws, and links pivoted in the core and having connection with the lever ends, said forming device being adapted to rest normally in the enlargement of the core but to be projected beyond said enlargement both laterally and longitudinally, substantially as and for the purpose set forth.

9. In a tool for forming bottle-necks, the combination with a central core having links 3 pivoted to its rear end, jaws pivotally connected to said links and provided with forming-surfaces at their forward ends, an enlargement near the forward end of said core, a forming device mounted in said core and formed in part by levers pivoted to the core and having connection with the jaws, and links pivoted in the core in advance of the enlargement and having connection with the lever ends, said forming device being adapted to rest normally in the enlargement of the core but to be projected beyond said enlargement both laterally and longitudinally when the jaws are moved toward each other, substantially as and for the purpose set forth.

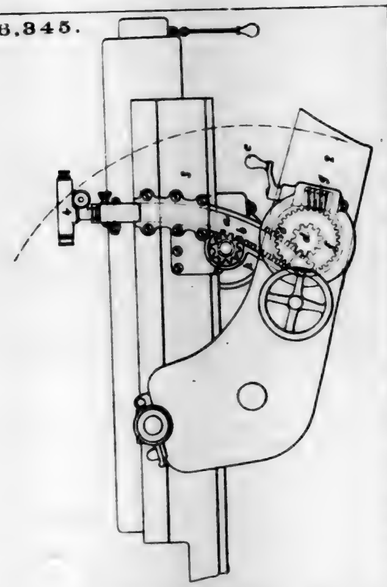
10. In a tool for forming bottle-necks, the combination with movable jaws and a central core, of levers connected with the core and operable by the jaws, members mounted in advance of the lever ends and also having connection with said lever ends, thus forming a compound forming device, the parts thereof being adapted to be projected into operative position both laterally and longitudinally with respect to the core, and retracted therefrom by the movement of the jaws, substantially as described.

706,845. APPARATUS FOR SIGHTING GUNS WITH INDEPENDENT LINE OF SIGHT. CHARLES P. E. SCHREIBER and JEAN B. G. A. CAREY, Le Creusot, France. Filed Jan. 29, 1901. Serial No. 45,305. (No model.)

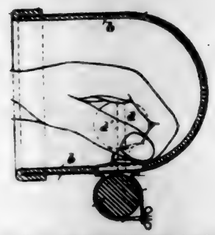
Claim.—1. The combination of a sight device, a gun, and its carriage, with a sector-shaped bar supporting the sight and with which the gun moves, a guide for said bar on the gun or cradle and concentric with the trunnions, means on the carriage for shifting said bar in a vertical plane, and gun elevating and depressing devices connected to the gun and to said bar.

2. The combination of a sight device, a gun and a gun-carriage of a gun elevating and depressing mechanism, a sector-shaped bar supporting the sight device and said elevating and depressing mechanism, a worm-gear operatively connected to said bar for elevating and depressing the same and thereby simultaneously moving the sight device and gun in a vertical plane without altering their angle of inclination to each other.

706,845.

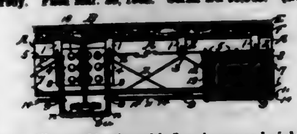


706,846. SHIELD FOR BICYCLE-HANDLES. OTTO SCHMIDT, Leutenberg, Germany. Filed Jan. 7, 1902. Serial No. 88,704. (No model.)



Claim.—The herein-described shield for the hands comprising a metallic body of an elongated cup shape having a soft lining falling back upon the outside to form rounded and smooth edges, a metallic block set in one side of the metallic body, a clamp-ring projecting outwardly from said metallic block, means for securing the clamp-ring to the shaft or bar, a pin projecting from the metallic block into the cup-shaped body, attached upon said ring in position to be gripped by the hand and projecting into the metallic body, substantially as described.

706,847. FIREPROOF FLOOR CONSTRUCTION. JOHN T. SIBLEY and MARSHALL E. SHOEMAKER, Jersey City, N. J., assignors to American Concrete-Steel Company, Newark, N. J., a Corporation of New Jersey. Filed Mar. 28, 1902. Serial No. 99,843. (No model.)



Claim.—1. The combination with floor beams and girders of main supporting metal bars, extending from beam to beam and attached thereto by means of stirrups, resting on the top flanges of the beams, diagonal rods, passing underneath and supported by said bars, and supporting-clips for said rods, the diagonal rods and clips forming a frame for the beam and girder casings, adapted to receive and hold the concrete or other plastic material, substantially as shown and described.

2. The combination with floor beams and girders, of main supporting metal bars extending from beam to beam, and attached thereto by stirrups resting on the top flanges of the beams, diagonal rods and supporting-clips, and diagonal wires and clips, passing down and about the beams and girders and located in such position as to allow a sufficient amount of concrete or other plastic material being placed against and under the bottom flanges of the beams and girders, and a body of concrete, or other plastic material placed around and about the same, all as substantially shown and described.

3. The combination with floor beams and girders, of main supporting metal bars extending from beam to beam, and attached thereto by means of stirrups resting on the top flanges of the beams, diagonal rods and their supporting-clips diagonal wires and clips passing down and about the beams and girders, and located in such position as to allow of a sufficient amount of concrete or other plastic material being placed against the web and under the bottom flanges of the beams and girders, a centering attached thereto, and passing around the space between and down and up the sides of and under the flanges of the beams and girders and forming a supporting-center on which the concrete or other plastic material is placed from above, said centering being used only for the support of concrete or other plastic material while the concrete or other plastic material is being placed around and about the supporting beams and girders, bars, rods, clips, &c., to form the body of the floor, and the beam and girder casing, substantially as shown and described.

4. The combination with floor beams and girders of main supporting metal bars extending from beam to beam, and attached thereto by means of stirrups resting on the top flanges of the beams, diagonal rods and their supporting-clips diagonal wires and clips, passing down and about the beams and girders, and located in such position as to allow of a sufficient amount of concrete or other plastic material being placed against the web and under the bottom flanges of the beams and girders, a wooden centering of the ordinary form, placed under and about the supporting beams, girders, bars, rods, clips, &c., forming a supporting-center on which the concrete or other plastic material is placed from above, said centering above mentioned being used only for the support of the concrete or other plastic material, while the concrete or other plastic material is being placed around and about the supporting beams, girders, bars, rods, clips, &c., to form the body of the floor and the beam, and girder-casing, said centering being removed after the concrete or other plastic material has become set or hardened, substantially as shown and described.

5. The combination with floor beams and girders, of main supporting-bars, extending from beam to beam, and attached thereto by means of stirrups resting on the top flanges of the beams, diagonal rods and their supporting-clips, diagonal wires and clips, passing down and about the beams and girders and located in such a position as to allow of a sufficient amount of concrete or other plastic material being placed against the web and under the bottom flanges of the beams and girders, a wire or metal lath, expanded metal, or similar centering attached thereto and passing across the space between and down and up the sides, and under the flanges of the beams and girders, and forming a supporting-center upon which the concrete or other plastic material is placed from above, substantially as shown and described.

6. The combination with beams A girders B, and main supporting-bars 2 extending between the supporting-beams A and attached thereto by means of suitable connections, diagonal rods 5 extending diagonally between beams A and passing under the bars 2 and attached thereto by means of clips 3 and 6, diagonal wires 7 and 8 placed alongside of and parallel with the webs of beams A and girders B, and clips 9 and 9ª secured to the bottom flanges of the beams A and girders B, diagonal wires 10 passing between clips 9 and 9ª across and under the bottom flanges of beams A and girders B, parallel wires 11 attached to clips 9 and running parallel with and below the bottom flanges of beams A and girders B, and clips 4 attached to bars 2 and supporting-wires 8 of the girder-casing, all substantially as shown and described.

7. The combination with beams A, girders B and main supporting-bars 2 extending between the beams A and attached thereto by means of stirrups 1, rods 5 extending diagonally between beams A passing under the bars 2 and attached thereto by means of clips 3 and 6, diagonal wires 7 and 8 placed alongside of and parallel with the webs of beams A and girders B, clips 9 and 9ª secured to the bottom flanges of the beams A and girders B, diagonal wires 10 passing between clips 9 and 9ª across and under the bottom flanges of beams A and girders B, parallel wires 11 attached to clips 9 and running parallel with and below the bottom flanges of beams A and girders B, clips 4 attached to bars 2 and supporting-wires 8 of the girder-casing, wires 14 passing diagonally between beams A and attached to clips 9 and secured at their intersection by wires 4 supported by bars or rods 15 running parallel with beams A, said bars 15 being supported from the main bars 2 by means of suspension-wires 16, substantially as shown and described.

8. In a fireproof floor and ceiling structure, a clip composed of two

or more pieces secured together by means of rivets or bolts and provided with a plurality of pairs of upwardly-directed hooks, substantially as shown and described.

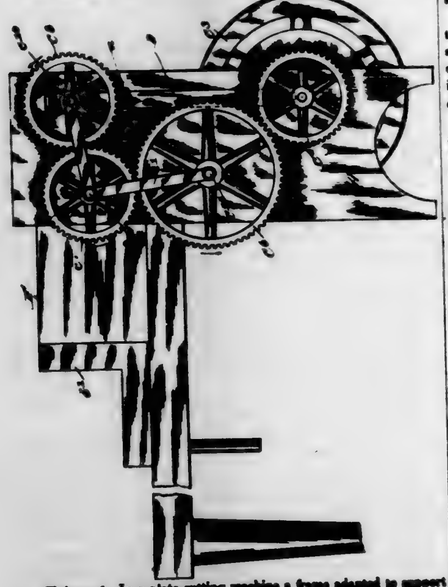
706,848. **FIREPROOF PARTITION STRUCTURE.** JOHN T. SHEPHERD and MARSHALL H. BROMBAKER, Jersey City, N. J., assignors to American Concrete-Steel Company, Newark, N. J., a Corporation of New Jersey. Filed Mar. 26, 1902. Serial No. 99,650. (No model.)

Claim.—1. In a partition construction, the combination with upright main supporting-bars, and diagonal bracing and binding members, passing across and attached to the same, of metal clips secured between the bars, and ceiling or floor materials to secure and change the direction of the diagonal members, and a metallic fabric or body secured thereto and against which the plaster is applied so as to embed and protect all parts of the metal frame against fire and securely hold the plaster or plastic material, substantially as shown and described.

2. In a fireproof partition construction, the combination with upright main supporting-bars and diagonal bracing and binding members passing across and attached to said bars, of clips secured between the bars and ceiling or floor materials to secure and change the direction of the diagonal wires so as to form a rigid framework, and a metallic body or fabric secured to said bars and diagonal members and connected as a centering against which plaster or other material is applied, substantially as shown and described.

3. A fireproof structure comprising upright supports provided at their upper and lower ends with clips having hooks, diagonally-arranged bracing and binding members connected with said hooks and with said supports so as to form in connection therewith a network and centering material connected with said network, substantially as shown and described.

706,849. **WOOD-PLATE-CUTTING MACHINE.** ANDREW SMITH, Chicago, Ill. Filed Oct. 16, 1901. Serial No. 78,809. (No model.)



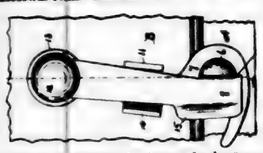
Claim.—1. In a plate-cutting machine a frame adapted to support a block from which the product is to be cut, a cutting-off knife adapted to engage said block, a means for reciprocating said knife, and a means for returning said knife and in connection with the reciprocating means for returning said knife to a position to begin another stroke within less time than that required to make the stroke.

2. In a plate-cutting machine a frame adapted to support a block from which the product is to be cut, a cutting-off knife adapted to engage said block, a means for reciprocating said knife, a means for rotating said knife and in connection with the reciprocating means for returning said knife to a position to begin another stroke within less time than that required to make the stroke, and a facing-knife adapted to face the block.

3. In a plate-cutting machine a revolubly cutting-off knife D^4, shafts C^{14} C^{15} to which opposite ends of said knife are attached, gear-wheels C^8 C^9 for rotating said shafts, bearing-supports for each of said shafts, adapted to be reciprocated, a means for reciprocating said bearing-supports, driving gear-wheels C^6 C^6 on a shaft common to both, intermediate shifting gear-wheels C^7 C^7 connecting the gear-wheels C^8 and C^9, a means for holding said shifting gear-wheels in train while gear-wheels C^8 C^9 are being reciprocated.

4. In a plate-cutting machine a driving-shaft C', bearings in which said shaft is journaled, shafts C^{14} C^{15}, a revolubly cutting-off knife having opposite ends fixed to and connecting said shafts, vertically-reciprocating journal-bearings for each of said shafts C^{14} on said bearings, guides in which said bearings are adapted to be reciprocated, means for coincidentally reciprocating said shafts, a driving-shaft C', gear-wheels C^8 C^9 on opposite ends of said driving-shaft, and an intermediate train of gearing for transmitting rotary motion therefrom to the shafts C^{14} C^{15}.

706,850. **HOOK FOR TYPE-WRITER COVERS.** EDWARD A. SMITH, Middletown, Conn. Filed Mar. 3, 1902. Serial No. 96,456. (No model.)



Claim.—1. The combination of a keeper in the form of a headed screw-body with an open hook mounted on an axis that extends transversely to the broad side of the said hook and parallel to the said keeper, for presenting the mouth of the hook to the side of the said keeper, and a separately-formed spring-latch having a pivotal eye by which it is mounted on the same axis as the said hook for locking the hook to said keeper, substantially as described.

2. A type-writer cover having swinging fastening-hooks mounted to swing in a plane parallel to the sides of the said cover to which the said hooks are secured, and spring-latches each latch having a pivotal eye by which it is mounted on the broad side of the said hooks for locking the said hooks into engagement with their keeper, substantially as described.

3. A hook having lugs on each side of its body in combination with a spring-latch pivoted on the axis of said hook, and with its body between the said lugs to hold the engaging ends of the said hook and latch in unison, substantially as described.

4. The combination of a hook for engaging a screw-like keeper having a head provided with a driving-slot with a spring-latch swinging with the said hook, and having the locking-lip adapted to engage the driving-slot in the end of the head of the said keeper, substantially as described.

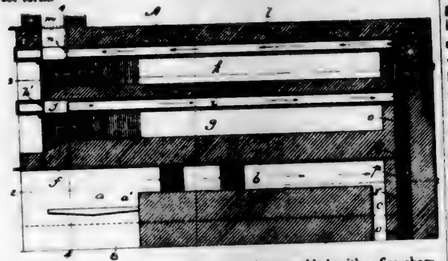
5. The combination of a hook for engaging a screw-like keeper with a spring-latch swinging with the said hook and having the longitudinally-extended locking-lip with its edge slanting backwardly from its outer end substantially as described.

6. The combination of a hook for engaging a screw-like keeper, with a spring-latch swinging with the said hook and having the locking-lip on one side of its outer end and the beveled wing 15 on the other side of the said end, substantially as described.

706,851. **BAKER'S OVEN.** GEORGE F. SMITH, Baltimore, Md. Filed May 13, 1902. Serial No. 107,084. (No model.)

Claim.—1. A baker's oven, comprising a casing provided at its front with a fire-chamber; flues leading rearwardly from said fire-chamber and opening at their rear into a downwardly-extending transverse dust-chamber, *c;* an oven above said flues and surmounted by longitudinally-extending flues, *i;* vertical flues, *f*, connecting said flues, *i*, at the front with said first-named flues; a combination dust and draft flue, *o*, adapted to connect said first-named flues at the rear with the stack or chimney and provided with a damper, *q;* and a dust-flue, *s*, connected to said combination-flue underneath said damper.

2. A baker's oven, comprising a casing provided with a fire-chamber; horizontal flues, *b*, and, *e*, leading from said fire-chamber; a transverse dust-chamber, *c*, opening downwardly from said flues at the rear and provided with a forwardly-opening dust-flue, *d;* an oven above said flues; longitudinally-extending flues, *i*, above said oven; vertical flues, *f*, connecting said longitudinally-extending flues, *i*, with said first-named flues, *b*, and, *e;* a combination dust and draft flue, *o*, extending entirely across the casing at the rear of said dust-chamber, *c*, and provided with a damper, *q;* and a dust-flue, *s*, leading from said combination-flue underneath said damper to the front of the casing, as and for the purpose set forth.



3. A baker's oven, comprising a casing provided with a fire-chamber; flues leading rearwardly from said fire-chamber; dust-chambers, *c*, opening downwardly from said flues at the rear; dust-flues, *d*, leading forwardly from said dust-chambers; a combination dust and draft flue, *o*, in the rear of said dust-chambers and provided with a damper, *q*, controlling communication between said first-named flues and the stack of the oven-casing; a dust-flue, *s*, leading forwardly from said combination-flue underneath said damper; and an oven, *g*, above said first-named flues, as set forth.

706,852. **UMBRELLA-STICK.** THOMAS H. SMITH, Lansford, Pa. Filed May 18, 1901. Serial No. 60,847. (No model.)

Claim.—1. In an umbrella, a stick constructed in telescopic sections, including a main or body section and a handle-section, a crown secured to the body-section, a runner mounted to slide upon the handle and the body sections, a spring located within the body-section and provided with projecting portions extending through openings in the body-section and arranged for frictional engagement with the runner when the latter is in its upper position, and having means for limiting the upward movement of the runner, a spring-controlled cam-support for the runner below and adjacent to the said spring, and a second spring located within the body-section of the stick and provided with feet arranged to extend through openings in the body-section, for the purpose set forth.

2. In umbrellas, a stick consisting of a tubular main section, a handle-section adapted to slide on the main section, and a ferrule-section adapted to slide in the main section, the ferrule-section having guided and locking connection with the main section, a crown secured to the main section, ribs pivoted to the crown, stretchers pivoted to the ribs, a runner having pivotal engagement with the stretchers, means for limiting the upward movement of the runner carried by the main section, a spring-latch carried by the main section and adapted for engagement with the upper end of the handle-section when the stick is lengthened, a cam-support for the runner, likewise carried by the main section of the stick and located above the said latch, a spring-controlled rod connected with the said cam, the said rod having a loop-section spanning the said latch, and means for operating said rod from the exterior of the said stick, as described.

3. In folding umbrellas, the combination, with a stick constructed in telescopic sections, embracing a ferrule-section, a tubular body-section and a tubular handle-section, the body-section being provided with a longitudinal slot having horizontal branches and the ferrule-section with a lug adapted to travel in the said slot and enter the said branches, of a spring-latch located within the body-section and adapted for engagement with the upper end of the handle-section of the stick when the stick is lengthened, a stop-spring located above the spring-latch, a runner arranged to travel on the handle and body sections of the stick, and having a downwardly-extending outwardly-flaring sleeve provided with an interior groove, the said stop-spring being arranged to engage the said groove and provided with extensions for limiting the upward movement of the runner, a cam-support for the runner pivoted on the body-section of the stick, a spring-controlled rod attached to the cam, a spring-controlled latch secured to the body-section of the stick and extending out through an opening therein, and a link connection between said latch and said rod, for the purpose described.

4. In folding umbrellas, the combination, with a stick constructed in telescopic sections, embracing a ferrule-section and a tubular body-section and a tubular handle-section, the body-section being provided at its outer end with a longitudinal slot having upper and lower branches, a lug extending from the ferrule-section into the said slot, means, substantially as described, for preventing one section of the stick turning on the other, a crown attached to the upper portion of the body-section of the stick, ribs pivoted to the crown, stretchers pivoted to the ribs, and a runner having a flaring sleeve mounted to slide upon the handle and the body sections of the stick, of a bridge-spring located within the body-section of the stick near its upper end, having feet extending out through openings in opposite sides of the said stick-section, which feet limit the upward movement of the runner, a cam-support pivoted upon the body-section of the stick below the said bridge-spring, a spring-controlled rod attached to the cam-support and extending downward through the body portion of the stick, a spring-controlled latch attached to the inner face of the body-section of the stick and extending out through an opening therein, a link connection between the latch and the rod, and a latch bridge-spring also located within the body-section of the stick, the feet whereof extend out through openings in the said section of the stick and serve to hold the handle-section of the stick in its lower position, as described.

5. In an umbrella a stick having a tubular main section, a handle-section adapted to slide on the main section and a ferrule-section adapted to slide in the main section, a crown secured to the main section, a runner adapted to slide on the handle and body sections, means for limiting the upward movement of the runner, a latch bridge-spring located within the body-section of the stick and having feet extending through openings in the said section, to hold the handle-section in its extended position, a support for the runner pivoted upon the body-section of the stick above the said bridge-spring, to hold the runner in its upper position, a spring-controlled rod connected at its upper end with the support for the runner, a spring-latch secured to the body-section and extending out through an opening therein and adapted to engage an opening in the handle-section when the latter is extended, and a connection between the said spring-latch and the lower part of the spring-controlled rod, substantially as set forth.

6. In an umbrella, a stick constructed in telescopic sections, a crown secured to one section, a runner adapted to slide upon two of said sections, and having a downwardly-extending and outwardly-flaring sleeve provided with an interior annular groove, means for limiting the upward movement of the runner, a spring-controlled cam-support for the runner, when the latter is in the upper position, and a spring-controlled latch adapted to engage the annular groove of the sleeve of the runner, when the latter is in its lowest position, substantially as described.

7. In an umbrella, a stick constructed in telescopic sections, a crown secured to the main or body section, a runner adapted to slide upon the handle and the body sections, a stop-spring located within the body-section and adapted to limit the upward movement of the runner, a spring-latch also located within the body-section below the stop-spring, for engagement with the upper end of the handle-section, when the stick is lengthened, a spring-controlled cam-support for the runner pivoted upon the body-section and located between the said stop-spring and the spring-latch, a latch secured to the main or body section and extending out through openings in the main and handle sections when the stick is extended, the said latch also serving to hold the runner in the lower position, and a connection between the said latch and the spring-controlled cam-support for the runner, substantially as described.

8. In an umbrella, the combination with a hollow stick having an inner or body section and an outer or handle section, and a runner there-

on, of a spring located within the inner section and provided with feet adapted to extend out through openings in opposite sides of the section the said feet being arranged for frictional contact with the runner, and provided with extensions at their upper portions to limit the upward movement of the runner, a cam for holding the runner in its uppermost position, and a second spring having feet extending out through opposite sides of the inner section of the stick for the purpose set forth.

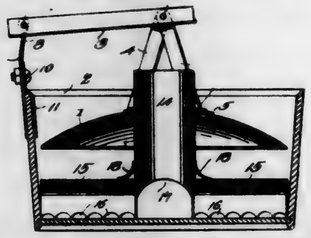
9. In an umbrella, the combination with a hollow stick, and a runner on the stick and having an internal annular groove, of a spring provided with feet extending out through opposite sides of the stick and adapted to enter the groove of the runner, and a pivoted runner-support below the projecting feet of the spring, as set forth.

10. In an umbrella, the combination with a hollow stick, and a runner on the stick and having an internal annular groove, of an arched spring having feet at the lower ends of its members, the outer edges of the feet being convex and adapted to enter the groove of the runner, a pivoted and spring-pressed runner-support below the projecting feet of the spring, a spring-latch adapted to enter the groove of the runner and hold it in its lowermost position, and an operative connection between the latch and the pivoted runner-support, as set forth.

11. In an umbrella, the combination with a hollow stick, and a runner on the stick, of an arched spring, having feet at the lower ends of its members extending out through opposite sides of the stick, the said feet being provided with horizontal extensions at their upper portions for limiting the upward movement of the runner, the side edges of said feet being arranged for frictional engagement with the runner, and means for supporting the runner in its uppermost position.

12. In umbrellas, a stick constructed of a tubular main section, a handle-section adapted to slide on the main section, the main section being provided at its upper end with a longitudinal slot having end extensions, a ferrule-section adapted to slide in the main section at the slotted portion and having a lug adapted to travel in the slot of the main section and to enter either of the end extensions of the slot, a crown secured to the main section, ribs pivoted to the crown, stretchers pivoted to the ribs, a runner having pivotal engagement with the stretchers, means carried by the main section for limiting the upward movement of the runner, a support for the runner when the latter is in its upper position, the said support being also carried by the main section, a spring also carried by the main section for holding the handle-section in the extended position, and a spring-latch for holding the runner in its lowest position, substantially as set forth.

706,853. WASHING-MACHINE. WILLIAM SPARKMAN, Orangeville, Tex. Filed May 1, 1902. Serial No. 105,505. (No model.)



Claim.—1. A washing-machine comprising a combined guide and overflow tube arranged in an upright position and designed to be placed in a suitable receptacle, and a pounder having an opening receiving the combined guide and overflow tube and adapted, when moved downward, to force water into the same, substantially as described.

2. A washing-machine comprising an upright tube designed to be placed in a receptacle and provided at its lower end with approximately semicircular arms forming a base, said tube being open at the top, and a pounder adapted when moved downward to expel water from clothes and force the said water into the tube, substantially as described.

3. A washing-machine comprising a combined guide and overflow tube arranged in an upright position and provided with a base having apertures, a concavo-convex pounder presenting a lower concave face and provided with a central opening receiving the tube, and means for operating the pounder, substantially as described.

706,854. METHYLENE DISALICYLIC ACID AND PROCESS OF MAKING SAME. SAMUEL L. SUMMERS, Philadelphia, Pa. Filed Apr. 26, 1902. Serial No. 104,221. (No specimens.)

Claim.—1. The new product described which is methylene disalicylic acid, a tasteless, impalpable creamy-white powder of granular construction, melting at 245° centigrade, having the empiric formula $C_{15}H_{12}O_4$, insoluble in water and benzol either hot or cold, slightly soluble in chloroform, and very soluble in ether and cold ethyl alcohol.

2. The process of producing methylene disalicylic acid which consists in heating to ebullition a saturated solution of salicylic acid to which has been added, in successive portions, concentrated hydrochloric acid and formaldehyde, then freeing the precipitate from all hydrochloric and unchanged salicylic acids by repeated washings in boiling water.

3. The process of producing methylene disalicylic acid by subjecting an alcoholic solution of salicylic acid to the action of hydrochloric and formaldehyde gases, in a suitable vessel, and then purifying the precipitate by washing in hot water.

706,855. ACET SALICYL PHENETIDIN AND PROCESS OF MAKING SAME. SAMUEL L. SUMMERS, Philadelphia, Pa. Filed Mar. 24, 1902. Serial No. 99,783. (No specimens.)

Claim.—1. As a new product the acet salicyl paraphenetidin herein described, which has the formula $C_{17}H_{17}NO_4$, melting at 92° centigrade, forming in white satin-like crystals, slightly astringent to the taste, and soluble in ether, alcohol and benzol.

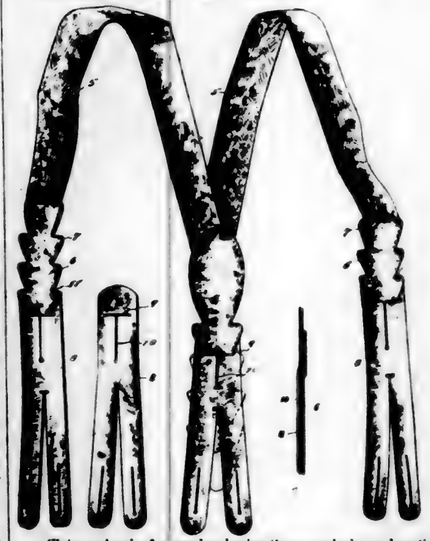
2. The process of producing the acet salicyl paraphenetidin herein described, which consists in heating one molecule of acet paraphenetidin with one molecule of brom-salicylic acid to a temperature of about 140° centigrade, until all acid vapors cease, then allowing the mass to cool, and finally extracting the crystalline body in a purified state by means of a suitable solvent.

706,856. ACET SALICYL PHENETIDIN AND PROCESS OF MAKING SAME. SAMUEL L. SUMMERS, Philadelphia, Pa. Filed June 5, 1902. Serial No. 110,293. (No specimens.)

Claim.—1. As a new pharmaceutical product, the acet salicyl paraphenetidin described, having the formula $C_{17}H_{17}NO_4$, melting at about 85° centigrade, forming in white needle-like crystals, tasteless, soluble in alcohol, ether, benzene and chloroform.

2. The process for producing the acet salicyl paraphenetidin described, which consists in first allowing oxychlorid of phosphorus to react on salicylic acid and paraphenetidin at a temperature of about 100° centigrade, and finally exhibiting the pure salicyl paraphenetidin thus formed to the action of acetic anhydrid, and purifying the resultant product by recrystallization.

706,857. SUSPENDERS. JOHN M. SUNDEAN, Lincoln, Nebr. Filed Sept. 30, 1901. Serial No. 77,117. (No model.)



Claim.—A pair of suspenders having three terminal or end portions formed of non-metallic material and each provided with a series of engaging shoulders, and button-straps adapted for engagement with any one of said end portions, said button-straps each comprising a single piece of flat leather having its lower portion bifurcated to form two button-engaging

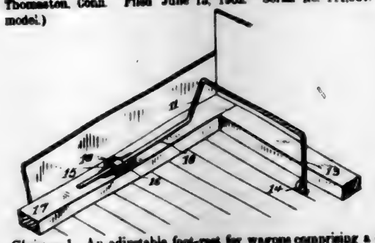
strips and its upper or head portion provided with a horizontally and a vertically slitted portion forming a T-shaped slot adapted for engagement with the shoulders on said end portions.

706,858. APPARATUS FOR ADMINISTERING ANESTHETICS. CHARLES K. TETER, Upper Sandusky, Ohio. Filed Apr. 16, 1902. Serial No. 103,224. (No model.)

Claim.—1. In a stand of the class described, the combination of a hollow standard having legs thereon, a stem adjustably mounted in said standard and bearing oppositely-extending arms bored throughout their length, a nipple formed on each of said arms, gas-cylinders connected to said arms, cocks mounted in said arms to regulate the flow of gas from said cylinders, a hollow arm connected to said arms intermediate said cocks and bearing a nipple, an adjustably-mounted gooseneck provided with a hook, a gas-bag suspended from said hook and provided with means for connecting it to a face-piece, and a hose-pipe connected to said gas-bag and said nipple, substantially as described.

2. In a stand of the class described, the combination with a standard, of legs hinged to said standard and provided with flanges which form feet, a collar slidingly mounted on said standard and carrying a set-screw, and brace-bars pivoted to said legs and said collar, said brace-bars being curved to adapt them to clear said feet so that said stand may be compactly folded, substantially as described.

706,859. FOOT-REST FOR CARRIAGES. ROLLIN THOMPSON, Thomaston, Conn. Filed June 13, 1902. Serial No. 111,507. (No model.)

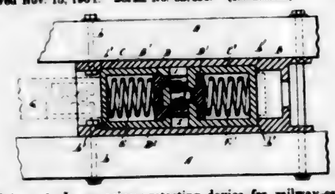


Claim.—1. An adjustable foot-rest for wagons comprising a clamp adapted for attachment at the sides of a wagon-bottom and a rest consisting of a longitudinal strip adapted to engage the clamp, a riser, a transverse piece and a brace descending therefrom and adapted to engage the bottom of the body at approximately its mid-width.

2. The foot-rest C made from a piece of rod-iron and consisting of a longitudinal strip 10, a riser 11, a transverse piece 12, a brace 13, and a head 14, substantially as shown, for the purpose specified.

3. The combination with a wagon-body, of clamps on opposite sides thereof and adjustable rests engaging said clamps and extending inward to approximately the mid-width of the body, each rest consisting of a longitudinal strip, a riser, a transverse piece, and a brace depending from the riser and engaging the bottom of the body.

706,860. SPRING-PROTECTING DEVICE FOR RAILWAY-CAR-COUPLING ATTACHMENTS. WILLIAM THORNBURGH, Detroit, Mich., assignor to the Thornburgh Coupler Attachments Company, Limited, Detroit, Mich., a Corporation of Michigan. Filed Apr. 8, 1901. Renewed Nov. 15, 1901. Serial No. 82,408. (No model.)



Claim.—1. In a spring-protecting device for railway-car-coupler attachments, box-followers, springs within said followers, and additional means to communicate pressure from one of said box-followers to the spring in the opposite box-follower.

2. In a spring-protecting device for railway-car-coupler attachments, box-followers normally separated the one from the other, springs located in said box-followers, and additional means to communicate pressure from one of said box-followers to the spring in the opposite box-follower.

3. The combination with box-followers and their associated instrumentalities, of a spring in each follower, a pin extension from one follower entering the other follower and engaging the spring thereof, and a pin extension from the other follower entering the first-mentioned follower and engaging the spring thereof, substantially as described.

4. The combination with box-followers each having a spring therein, of pin extensions from the respective followers entering the opposite follower and engaging the spring therein, substantially as described.

5. In a spring-protecting device for railway-car-coupler attachments, box-followers, plate-followers within the box-followers, draft-springs within the box-followers located between the corresponding plate-follower and the opposite end of the corresponding box-follower, and means whereby each plate-follower may communicate pressure applied thereto to the opposite box-follower.

6. In a spring-protecting device for railway-car-coupler attachments, box-followers, plate-followers within the box-followers, and draft-springs within the box-followers between the corresponding plate-follower and the opposite end of the corresponding box-follower, and arms projecting through the adjacent end wall of the box-followers, whereby each plate-follower may communicate pressure applied thereto to the opposite box-follower.

7. In a spring-protecting device for railway-car-coupler attachments, box-followers normally separated one from the other toward their adjacent ends, plate-followers within the box-followers, and draft-springs within the box-followers between the corresponding plate-follower and the opposite end of the corresponding box-follower, and arms projecting through the adjacent end walls of the box-followers, said arms contacting at their outer extremities with the adjacent end wall of the box-follower opposite that through which the arms project, whereby each plate-follower may communicate pressure applied thereto to the opposite box-follower.

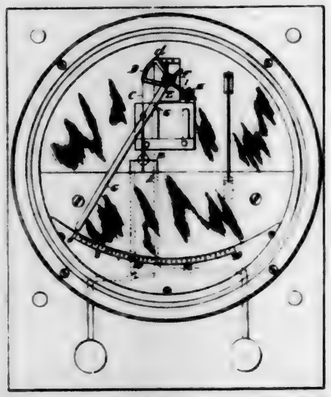
8. In a spring-protecting device for railway-car-coupler attachments, the combination with a draft-spring housing, of box-followers having a movable engagement therein and constructed to abut the one against the other at their adjacent ends, draft-springs within the box-followers, and additional means to communicate the spring tension in one of the box-followers to the spring in the other box-follower, the draft-spring housing constructed to limit the movement of the box-followers toward opposite ends thereof.

706,861. INSTRUMENT FOR MEASURING ELECTRIC CURRENTS. WILLIAM THOMSON, Glasgow, Scotland. Filed Dec. 30, 1897. Serial No. 664,582. (No model.)

Claim.—1. The combination of a coil or solenoid; a plunger reciprocating in the coil or solenoid; a beam carrying a pointer, a segment and an adjustable counterbalance-weight; a ligament secured at one end to the segment and at the other end supporting the plunger; a rod attached to the plunger, having a disk; and a vessel for containing fluid in which the disk is immersed to control the movement of the plunger.

2. An instrument for measuring electric currents comprising a coil or solenoid, a plunger reciprocating in the coil or solenoid, hooks having V-shaped recesses, a beam having knife-edges resting in the V-shaped

recesses, and carrying a pointer, a segment secured to the beam, a screw-threaded rod secured to the beam, counterbalance-weight adjustable on the screw-threaded rod, and a ligament secured at one end to the segment and at the other end supporting the plunger.



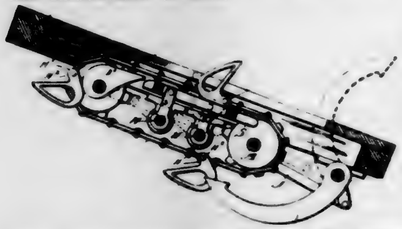
3. An instrument for measuring electric currents, comprising a coil or solenoid, a plunger reciprocating in the coil or solenoid, hooks having V-shaped recesses, a beam having knife-edges resting in the V-shaped recesses, and a pointer connected to the beam.

4. A coil or solenoid for an instrument for measuring electric currents, comprising a tube having a spiral cut.

5. A coil or solenoid for an instrument for measuring electric currents comprising inner and outer tubes having right and left hand spiral cuts respectively.

6. A coil or solenoid for an instrument for measuring electric currents, comprising a number of concentrically-arranged tubes each having a spiral cut.

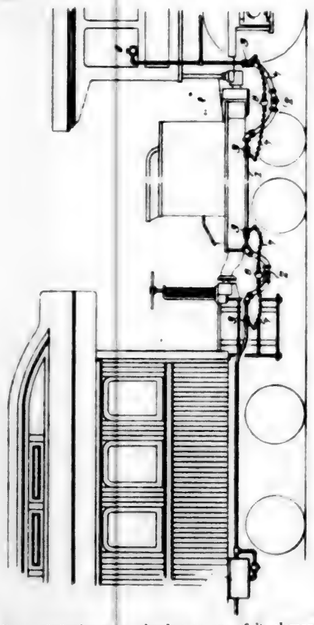
706,862. GRAIN-PACKER FOR HARVESTING-BINDERS. DANIEL H. THURSTON and JOHN F. HOLDEN, Plymouth, Iowa. Filed Feb. 13, 1901. Serial No. 47,179. (No model.)



Claim.—In a grain-packer for harvesting-machines, the combination with the binder-deck having longitudinal slots therein, rotating shafts mounted in the stubbleward and grainward portions of the deck below the slots, sprocket-wheels on said shafts having chains thereon, and oppositely-arranged packer-fingers pivoted on said chains, cam-shaped guides secured on the grainward shaft coacting with the fingers to project the same upwardly through the slots, of shafts carrying a pivoted endwise-movable frame for supporting the fingers during their movement along the slots, a shaft at the stubbleward end of the frame, a binder-needle thereon, a crank-arm on said shaft, a crank-arm on one of the shafts of the endwise-movable frame, and a pitman connected to said crank-arms whereby the supporting-frame is adapted to be swung downward during the motion of the needle-shaft thereby withdrawing the fingers from operative position, substantially as specified.

706,863. AIR-BRAKE ATTACHMENT. ARTHUR L. TIBBITS, Chicago, Ill. Filed Nov. 15, 1901. Serial No. 82,482. (No model.)

Claim.—1. The combination with an automatic air-brake system having the usual auxiliary reservoirs, brake-cylinders, engineer's brake-valve and train-pipe, of an auxiliary pipe independent of the automatic brake system, said auxiliary pipe extending throughout the length of the train and to the cab of the engine, said pipe being connected directly to the auxiliary reservoirs and forming a bleeder, a valve arranged in the cab independent of the engineer's brake-valve and controlling the flow of air from the auxiliary reservoirs, normally open valves arranged on said auxiliary pipe at points adjacent to the ends of the cars, and means for automatically closing said valves on the parting of the train, substantially as specified.



2. In an air-brake system having as one of its elements, an auxiliary reservoir on each car, an auxiliary pipe connected to each of the reservoirs and having coupled sections between the cars, cocks arranged on said pipe at the ends of the car, a separable coupling member for connecting adjacent cocks and adapted to operate the same upon the parting of a train, and a controlling-valve on said pipe.

3. In an air-brake system having as one of its elements an auxiliary reservoir on each car, an auxiliary pipe connected to each of the reservoirs by a valved branch pipe, cocks arranged on said pipe at each end of the cars, flexible couplings arranged on the pipe between the cars and a separable coupling-member connecting said valves, said member being adapted to be uncoupled in advance of the uncoupling of the pipe members, and a controlling-valve on said pipe, substantially as specified.

706,864. WATCHMAKER'S EYEGLASS. HORMIDAS TREMBLAY, Southbridge, Mass. Filed Dec. 26, 1901. Serial No. 87,320. (No model.)

Claim.—1. A watchmaker's eyeglass comprising a two-part frame having its members spaced apart by permanently-secured rivets, a spring held in place by the rivets, and a lens-ring and an eye-ring each carrying a lug provided with an angularly-disposed slot to engage the respective rivets, and bearing at their ends upon the terminals of the spring.

2. A watchmaker's eyeglass comprising a two-part frame having its members spaced apart by permanently-secured rivets, a spring held in place by the rivets, a lens-ring and an eye-ring each carrying a lug provided with an angularly-disposed slot to engage the rivets and bearing at their ends upon the terminals of the spring, and stops carried by the frame members for holding the lens-ring out of contact with the frame.

706,865. TREATMENT OF GOLD AND SILVER ORES. SIDNEY TREVICK, Clapham Common, England. Filed Oct. 30, 1899. Serial No. 735,270. (No specimens.)

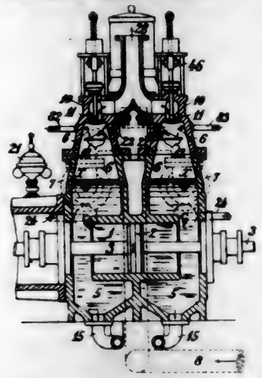
Claim.—1. A process for evolving nascent chlorin and effecting the chlorination of metals in order that they may be extracted from a metalliferous mass by rendering them solvent consisting in adding to the mass a mixture in definite proportions of two dilute solutions, one being a solution of calcium hypochlorite free from calcium hydrate, and the other a solution of ferric chlorid, the proportions being such as to result in the formation of ferric hypochlorite leaving some excess of ferric chlorid, which will evolve nascent chlorin.

2. A process for evolving nascent chlorin and effecting the chlorination of metals in order that they may be extracted from a metalliferous mass by rendering them solvent consisting in adding to the mass a mixture in definite proportions of two dilute solutions, one being a solution of calcium hypochlorite free from calcium hydrate, and the other a solution of ferric salt, the proportions being such as to result in the formation of ferric hypochlorite and ferric chlorid which will evolve nascent chlorin.

3. A process for evolving nascent chlorin and effecting the chlorination of metals in order that they may be extracted from a metalliferous mass by rendering them solvent consisting in adding to the mass a mixture in definite proportions of two dilute solutions, one being a solution of hypochlorite of a metal of the alkali groups, and the other a solution of ferric chlorid, the proportions being such as to result in the formation of ferric hypochlorite leaving some excess of ferric chlorid, which will evolve nascent chlorin.

4. A process for evolving nascent chlorin and effecting the chlorination of metals in order that they may be extracted from a metalliferous mass by rendering them solvent consisting in adding to the mass a mixture in definite proportions of two dilute solutions, one being a solution of hypochlorite of a metal of the alkali groups, and the other a solution of ferric salt, the proportions being such as to result in the formation of ferric hypochlorite and ferric chlorid, which will evolve nascent chlorin.

706,866. INTERNAL-COMBUSTION MOTOR. ADOLF VOGT and MAX VON RECKLINGHAUSEN, Westminster, London, England. Filed June 25, 1901. Serial No. 66,008. (No model.)



Claim.—1. An internal-combustion engine comprising a horizontal cylinder with its working piston, a vertical extension at each end of said cylinder closed at the upper end and charged with liquid constituting liquid extensions of said piston, spaces in said cylinder extensions above the liquid for containing the explosive charges, means for introducing and exploding said charges alternately in each cylinder extension so that on the explosion of a charge in the one extension, the liquid will be forced downward therein, causing the piston to drive the liquid upward in the other extension, and to compress an explosive charge previously admitted therein, and means for discharging the combustion-gases from the cylinder extensions and for forcing in a charge of air under pressure after each explosion, substantially as described.

2. An internal-combustion motor comprising a horizontal working cylinder and its piston, the ends of the cylinder being formed into upwardly-extending chambers having closed coned upper ends and being partly filled with liquid that constitutes extensions of the piston, means for introducing combustible charges alternately into each chamber above the liquid, means for exploding such charges and thereby forcing downward the corresponding liquid column and causing the piston to perform its stroke to propel upward the other liquid column to compress an explosive charge previously admitted above it, means for introducing a scavenger charge of air into said chambers after each explosion for expelling the combustion-gases and supplying the air required for the next explosive charge, and means for discharging a portion of liquid from such chambers after each explosion and introducing a body of fresh liquid, substantially as described.

3. An internal-combustion motor comprising a horizontal working cylinder and its piston, the ends of the cylinder constituting upwardly-extending chambers having closed coned upper ends and containing liquid that constitutes extensions of the piston, means for introducing combustible charges alternately into each chamber, means for exploding such charges and thereby forcing downward the corresponding liquid column and raising the other liquid column, valve devices for discharging the products of combustion from and for admitting a scavenger charge of air into the space above the liquid column after each explosion, a forcing device for forcing an air-supply through said scavenger-valve device, a forcing device for forcing a fresh quantity of liquid into the liquid column after each explosion, and a valve device communicating with the lower part of the working cylinder for discharging a quantity of liquid from the liquid column when the compression-pressure exceeds a predetermined amount, substantially as described.

4. An internal-combustion motor comprising a horizontal working cylinder and its piston, upwardly-extending chambers at each end of the cylinder, charged with liquid forming extensions of the piston, means for the introduction of combustible matter for the combustible charges into the upper ends of said chambers, means for introducing air under pressure after each explosion for expelling the combustion-gases and supplying the air to mix with the combustible matter for forming the next explosive charge, a discharge-valve device for the escape of the combustion-gases, means for forcing liquid into the cylinder extensions after the explosion of a charge therein and means for allowing a controlled escape of the liquid therefrom during the upward motion of the liquid column in the one extension consequent on the explosion of a charge in the other extension, substantially as and for the purposes described.

5. An internal-combustion motor comprising a horizontal working cylinder and its piston, upwardly-extending chambers at each end of the cylinder having coned upper ends and charged with liquid forming extensions of the piston, means for the introduction of combustible matter into the coned ends of said chambers, a discharge-valve device for the combustion-gases at the upper end of each cylinder extension, a valve device for the admission of air under pressure into the upper part of each cylinder extension after the explosion of each combustible charge, means for forcing liquid into each cylinder extension after the explosion of a charge therein, a loaded escape-valve device, communicating with the lower end of each cylinder extension, and adapted to allow the escape of liquid therefrom when on the compression-stroke of the piston the compression-pressure exceeds the load on the valve, and a valve device adapted to close the said communication between the cylinder extensions and the loaded escape-valve at all times except during the compression-strokes of the piston, substantially as described.

6. An internal-combustion motor comprising a horizontal working cylinder and its piston, upwardly-extending closed chambers at each end of the cylinder charged with liquid, a valve device for the introduction of combustible matter into each cylinder extension, a valve device for the discharge of the combustion-gases after each explosion of a combustible charge, a valve device for the admission of air under pressure into each cylinder extension after each explosion for forming the next explosive charge, means for forcing liquid into each cylinder extension after each explosion, means for allowing the escape of liquid from each cylinder extension during the compression-stroke when the pressure exceeds a predetermined amount, and governor-controlled mechanism for varying the duration of the opening of the said discharge-valve according to variations in the load on the motor, substantially as and for the purpose described.

7. An internal-combustion motor comprising a horizontal working cylinder and its piston, upwardly-extending closed chambers at each end of the cylinder charged with liquid, a valve device for the introduction of combustible matter into each cylinder extension, a valve device for the discharge of the combustion-gases after each explosion of a combustible charge, a valve device for the admission of air under pressure into each cylinder extension after each explosion for forming the next explosive charge, means for forcing liquid into each cylinder extension after each explosion, means for allowing the escape of liquid from each cylinder extension during the compression-stroke when the pressure exceeds a predetermined amount, and governor-controlled mechanism for varying the duration of the opening of the said discharge-valve according to varia-

tions in the load on the motor and also to vary the time of opening and duration of opening of the said inlet-valve for combustible matter so that, on the one hand, it shall only open after the closing of the said discharge-valve, and on the other hand, the quantity of combustible matter shall vary according to variations in the load on the motor, substantially as described.

8. An internal-combustion motor comprising a horizontal working cylinder and its piston, upwardly-extending closed chambers at each end of the cylinder charged with liquid, a valve device for the introduction of combustible matter into each cylinder extension, a valve device for the discharge of the combustion-gases after each explosion of a combustible charge, a valve device for the admission of air under pressure into each cylinder extension after each explosion for forming the next explosive charge, means for forcing liquid into each cylinder extension after each explosion, means for allowing the escape of liquid from each cylinder extension during the compression-stroke when the pressure exceeds a predetermined amount, and governor-controlled means for varying the quantity of liquid forced into the cylinder extensions after the explosion of each charge, according to variations in the load on the motor, substantially as described.

9. An internal-combustion motor comprising a horizontal working cylinder and its piston, upwardly-extending chambers at each end of the cylinder charged with liquid and having closed upper ends, each provided with a valve device for the introduction of combustible matter, a valve device for the discharge of the combustion-gases after each explosion of a combustible charge, a valve device for the admission of air under pressure into each cylinder extension after each explosion for forming the next explosive charge, means for forcing liquid into each cylinder extension after each explosion, means for allowing the escape of liquid from each extension during the compression-stroke when the compression-pressure exceeds a predetermined amount, a governor, controlling mechanism connecting the said discharge-valve, the inlet-valves for compressed air, and fuel, and the device for forcing liquid into the cylinder extensions with the engine-governor, so as, according to variations in the load of the motor, to vary the duration of the opening of the discharge-valve, to vary the quantity of air remaining in the cylinder extensions after the closing of the discharge-valve, to vary the time and duration of the opening of the valve device for the admission of combustible matter, and to vary the amount of liquid admitted to the cylinder extensions after each explosion for the purpose of varying the volume of the combustible charges according to the varying load on the motor, while maintaining the composition of such charges and the degree to which they are compressed constant, substantially as described.

10. An internal-combustion motor comprising a working cylinder open at both ends, each end being in a separate chamber, which chamber is filled with liquid and terminates above in an upwardly-coned explosion-chamber, the said explosion-chamber being fitted with a device for injecting combustible matter, a scavengering-valve for the introduction of air under pressure, a valve for the discharge of combustion-gases, and an igniting device: pumps for supplying the compressed air and the said liquid; and a valve for allowing liquid to flow from either cylinder-chamber, the said valve being loaded so that only when compression of the explosive charges exceeds a predetermined pressure it will allow the escape of liquid, substantially as and for the purpose described.

11. An internal-combustion motor comprising a working cylinder open at both ends, each end being in a separate chamber, which chamber is filled with liquid and terminates above in an upwardly-coned explosion-chamber, the said explosion-chamber being fitted with a device for injecting combustible matter, a scavengering-valve for the introduction of air under pressure, a valve for the discharge of combustion-gases, and an igniting device; pumps for supplying the compressed air and the said liquid; and a valve for allowing liquid to flow from either cylinder-chamber, and a regulating mechanism for causing the combustible matter to be introduced immediately after the closure of the discharge-valve, consisting of a lever 58, toothed wheelwork 57, 59, 60, 61, turned by the valve-motion shaft 20 and a casing 62 capable of rotation with respect to the lever 58, the nave of which casing runs free on the valve-motion shaft and carries tappets 40, 41, in whose paths are the bell-cranks 39 that actuate the mechanism for introducing the combustible matter, the said lever 58 being connected with a lever 67 actuated by the governor so that when during the rotation of the valve-motion shaft the toothed wheelwork is turned backward by the governor through the lever 58, the tappets 40, 41, actuate the levers 39 somewhat later, substantially as described.

12. An internal-combustion motor comprising a working cylinder open at both ends, each end being in a separate chamber, which chamber is filled with liquid and terminates above in an upwardly-coned explosion-chamber, the said explosion-chamber being fitted with a device for injecting combustible matter, a scavengering-valve for the introduction of air under pressure, a valve for the discharge of combustion-gases, and an igniting device; pumps for supplying the compressed air and the said liquid; and a valve for allowing liquid to flow from either cylinder-chamber, and a device for regulating the compression of the explosive charges consisting of a rotary valve 13 combined with a loaded valve 14, for the escape of liquid, which rotary valve is actuated by the valve-motion shaft in such manner that the valve 14 is put in communication with that explosion-chamber in which a charge is being compressed, the said rotary valve receiving this motion through the levers 56 which open the scavengering-valve 9 and through telescopic rods 69, 70, carrying collars 71, 72, and connected with cranks on the spindle of the rotary valve so that the latter is alternately moved into the position in which it allows liquid to flow from the one cylinder or the other through the valve 14, substantially as described.

13. An internal-combustion motor comprising a working cylinder open at both ends, each end being in a separate chamber, which chamber is filled with liquid and terminates above in an upwardly-coned explosion-chamber, the said explosion-chamber being fitted with a device for injecting combustible matter, a scavengering-valve for the introduction of air under pressure, a valve for the discharge of combustion-gases, and an igniting device; pumps for supplying the compressed air and the said liquid; and a valve for allowing liquid to flow from either cylinder-chamber, and a starting-gear consisting of a compressed-air pipe and a three-way cock 74 making communication between the said air-pipe and one or other side of the working cylinder, the said cock being turned by the engagement of a coupling 87, 88, at the same time that the cut-off cock 77 of the compressed-air pipe is turned, in order that compressed air may flow into one or the other of the explosion-chambers, substantially as described.

14. An internal-combustion motor comprising a horizontal working cylinder and its piston, an upwardly-extending chamber at each end of the cylinder charged with liquid that constitutes extensions of the piston, means to blow an explosive charge into the extensions above the liquid-level therein, a discharge-valve and a valve controlling the admission of compressed air in each extension, a pump operated by the motor to force liquid into each extension after each explosion, means to vent liquid from the bottom of each chamber, a compressor connected to the piston to send scavengering air under pressure into the extensions, valve mechanism controlling compressed air to start the motor, and an independent compressor operated by the motor to supply air to the cylinder extensions through the starting mechanism, substantially as described.

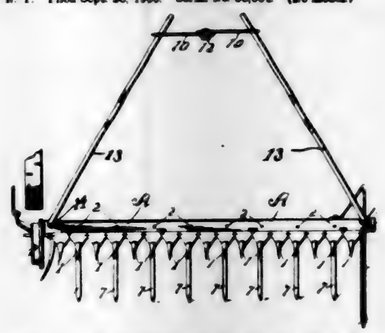
15. An internal-combustion motor comprising a horizontal working cylinder and its piston, chambers at each end of the cylinder charged with liquid that constitutes extensions of the piston, means to blow an explosive charge into the extensions above the liquid-level therein, a loaded discharge-valve and a valve controlling the admission of compressed air into each extension, a pump operated by the motor to force liquid into each extension after each explosion, means to vent liquid from the bottom of each chamber, a valve to control the venting of fluid from the chambers, means to send scavengering air under pressure into the extensions, a valve-motion shaft, means thereon to actuate the feed of the charge, devices thereon to actuate the discharge-valves, devices thereon to actuate the valves controlling scavengering air and simultaneously operate the valve venting liquid from the chambers, a governor, and a shaft controlled thereby and connections between said shaft and means to blow in the charge to control the introduction thereof, and auxiliary means connected to said shaft to control the operation of the exhaust-valves, substantially as described.

16. An internal-combustion engine comprising a horizontal cylinder with its working piston, an extension at each end of the cylinder charged with liquid that constitutes liquid extensions of the piston, means for introducing and exploding explosive charges alternately in said chambers above the liquid-level therein, means for discharging the combustion-gases, means to force in a charge of air under pressure after each explosion, a rotatable starting-valve controlling air under pressure to admit said air alternately to the chambers and hand-operated clutch mechanism to engage a rotating element to actuate the valve, substantially as described.

17. An internal-combustion engine comprising a horizontal cylinder with its working piston, an extension at each end of the cylinder charged with liquid that constitutes liquid extensions of the piston, means for introducing and exploding explosive charges alternately in said chambers above the liquid-level therein, means to discharge the combustion-gases, means to force in a charge of air under pressure after each explosion, a driven valve-motion shaft, a gear-wheel loose thereon, a clutch-sleeve on the shaft to engage said wheel, a rotatable starting-valve controlling air under pressure, a gear-wheel on the valve meshing with that on the valve-motion shaft, substantially as described.

18. An internal-combustion motor, comprising a horizontal cylinder with its working piston, an extension at each end of the cylinder charged with liquid that constitutes liquid extensions of the piston, a pulverulent fuel-container on each extension, a fuel-injector, a fuel-feed to deliver a determined quantity of fuel from the container to the injector to be blown into the chambers above the liquid-level therein, means to discharge the combustion-gases therefrom, means to force in a charge of air under pressure after each explosion and a valve-motion shaft to actuate the fuel-feed, a governor-controlled shaft, and means connected thereto to vary the quantity of fuel fed to the fuel-feeding device, substantially as described.

706,367. HARVESTER. WARREN S. WARBURN, Adams Center, N. Y. Filed Sept. 20, 1900. Serial No. 30,604. (No model.)



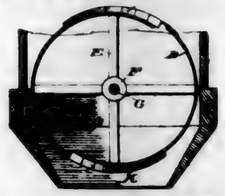
Claim.—1. The combination with a finger-bar provided with fingers, of guards secured to the finger-bar and extending forwardly therefrom beyond the fingers, that portion of the guards in front of the fingers forming a downwardly-inclined prolongation of the fingers and terminating in a slight upward incline, without returning toward the finger-bar, the downwardly-inclined prolongation forming a runner resting upon the ground, and the rearward portion of the guards located beneath the fingers.

2. In a harvester, the combination with a finger-bar provided with fingers, of guards secured to the finger-bar and extending forwardly therefrom beyond the fingers, that portion of the guards in front of the fingers forming a downwardly-inclined prolongation of the fingers, and terminating in a slight upward incline without returning toward the finger-bar, the downwardly-inclined prolongation forming a runner at the extreme end to prevent contact of the point of the guard with the ground, and the rearward portion of the guards located beneath the fingers, the harvester provided also with a divider secured to the finger-bar and a pair of movable wings or windrowers extending rearwardly of the finger-bar to which they are pivoted.

3. The combination with a finger-bar provided with fingers, of a guard for the fingers, having a portion bent to conform to the lower surface of the fingers and constituting runners therefor, said guards having shoulders formed with an opening to receive the point of the finger and the forward terminating ends constituting an extension or elongation of the fingers, and the rear ends having a hole therein in alinement with the hole in the fingers and finger-bar, whereby the guard and finger are secured to the finger-bar by the same bolt, the rear ends of the guards and fingers terminating in approximately the same plane as the rear edge of the finger-bar.

4. The combination with a pair of wings pivoted or hinged at their forward ends adjacent to the opposite ends of the finger-bar of a harvester, of a pair of arms, one of which is connected with each wing at or near the rear end thereof, said arms formed into loops at their free ends and means connecting the ends whereby they can be secured adjustably together to regulate the space between the rear ends of the wings.

706,368. MACHINE FOR CUTTING VEGETABLE-ROOTS. HENRY WEBB, Ashton, Mich. Filed Apr. 8, 1901. Serial No. 54,941. (No model.)

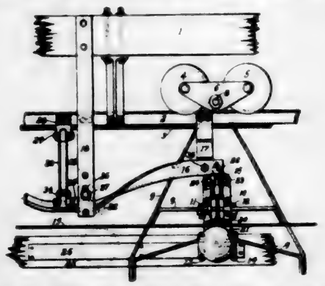


Claim.—1. In a vegetable-cutter, a rotary drum having a portion of its periphery curved gradually inward and thus made eccentric, and a series of openings located at the edges of such eccentric portion and a series of cutters arranged stepwise over said openings and differing in height, substantially as shown and described.

2. In a vegetable-cutter, a rotary drum, having a series of peripheral openings arranged on divergent lines, and cutters which are right angular in form and arranged over said openings, substantially as shown and described.

3. In a vegetable-cutter, the rotary drum, provided with peripheral openings, and cutters arranged on divergent lines, the ends of the drum being notched as described to provide for discharge of the severed pieces of the roots, substantially as shown and described.

706,369. GRIP-ACTUATING MECHANISM. SAMUEL S. WEBBER, Trenton, N. J. Filed Apr. 12, 1902. Serial No. 102,503. (No model.)

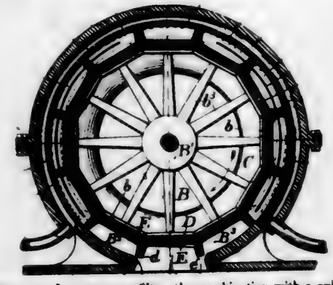


Claim.—1. In a grip-actuating mechanism, a member having a bearing-surface the plane of which bearing-surface is, at one end thereof, at an angle with its plane at the other end thereof, said bearing-surface being placed in the line of motion of an actuating member of a gripping mechanism, and adapted by contact therewith to force a closure of the jaws of said gripping mechanism, in combination with means for affording a yielding contact between said bearing-surface and said actuating member.

2. In a grip-actuating mechanism, a member having a bearing-surface the plane of which bearing-surface is, at one end thereof, at an angle with its plane at the other end thereof, said bearing-surface being placed in the line of motion of an actuating member of a gripping mechanism, and adapted by contact therewith to force a closure of the jaws of said gripping mechanism, in combination with means for affording a yielding contact between said bearing-surface and said actuating member, and auxiliary means for enforcing such contact.

3. The combination of a gripping mechanism having an actuating member, a member having a curved bearing-surface the plane of which bearing-surface is, at one end thereof, at an angle with its plane at the other end thereof, said bearing-surface being placed in the line of motion of said actuating member of said gripping mechanism, and adapted by contact therewith to force a closure of the jaws of said gripping mechanism, means for affording a yielding contact between said bearing-surface and said actuating member, and auxiliary means for enforcing such contact.

706,370. FILTER. FRANK S. YOUNG, Norristown, and WILLIAM W. UBBERROTH, South Bethlehem, Pa., assignors of one-fourth to Henry De Huff, Philadelphia, Pa. Filed Oct. 21, 1901. Serial No. 79,469. (No model.)



Claim.—1. In a pressure-filter, the combination with a cylindrical casing; of a drum mounted to turn in said cylindrical casing, pockets in said drum, filter-cloths in said pockets, and means for conducting mate-

rial to said pockets, and for conducting liquid from said pockets, and springs in said pockets for throwing the solid material out, substantially as described.

2. In a pressure-filter, the combination with a cylindrical casing having a discharge-opening therethrough, of a drum mounted to turn in said cylindrical casing, pockets in said drum, filter-cloths in said pockets, means for conducting material to said pockets, means for conducting the liquid away from said pockets, means for discharging the contents from said pockets and means for cutting off the flow of material to said pockets while passing the discharge-opening, substantially as described.

3. In a pressure-filter, the combination with a cylindrical casing having interior corrugations a filter-cloth, and a perforated plate covering said corrugations, of a drum mounted to turn in said casing and having pockets in its periphery, corrugations in said pockets, means for conducting material into said pockets, and for conducting the liquid away from said pockets, and means for ejecting the solid material from said pockets, substantially as described.

4. In a pressure-filter, the combination with a cylindrical casing having interior corrugations, a filter-cloth, and a perforated plate covering said corrugations, of a drum mounted to turn in said casing and having pockets in its periphery, corrugations in said pockets, means for conducting material into said pockets, and for conducting the liquid away from said pockets, means for discharging the solid material from said pockets and means for cutting off the flow of material to the pockets while said discharge is taking place, substantially as described.

5. In a pressure-filter, the combination with a cylindrical casing having interior corrugations and outlet-passages communicating with said corrugations a filter-cloth, and a perforated plate covering said corrugations, of a drum mounted to turn in said casing, pockets in said drum having corrugations, means for conducting material to said pockets, and means for ejecting the solid material therefrom, substantially as described.

6. In a pressure-filter, the combination with a cylindrical casing having passages communicating with the interior thereof, corrugations in the interior of said casing, a filter-cloth, and a perforated plate covering said corrugations, of a drum mounted to turn in said casing and having pockets in the periphery thereof, and passages communicating with said pockets, corrugations in said pockets, filter-cloths in said pockets, and means for ejecting the solid material from said pockets, substantially as described.

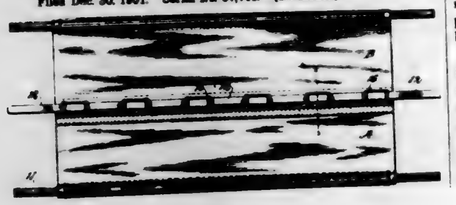
7. In a pressure-filter, the combination with a cylindrical casing having passages communicating with the interior thereof, corrugations in the interior of said casing, a filter-cloth and a perforated plate covering said corrugations, of a drum mounted to turn in said casing and having pockets in the periphery thereof, and passages communicating with said pockets, corrugations in said pockets, means for cutting off the flow of material to the pockets at intervals, and means for ejecting the solid material from the pockets, substantially as described.

8. In a pressure-filter, the combination with a cylindrical casing having interior corrugations, a filter-cloth, and a perforated plate covering said corrugations, of a drum mounted to turn in said casing and having pockets in its periphery, corrugations in said pockets, means for conducting material into said pockets, and for conducting the liquid away from said pockets, and means for ejecting the solid material from said pockets, substantially as described.

9. In a pressure-filter the combination with a cylindrical casing, having interior corrugations, a filter-cloth, and a perforated plate covering said corrugations, of a drum mounted to turn in said casing and having pockets in its periphery, corrugations in said pockets, filter-cloths in said pockets, means for conducting material into said pockets, and for conducting the liquid away from said pockets, and means for ejecting the solid material from said pockets, substantially as described.

10. In a pressure-filter, the combination with a cylindrical casing having interior corrugations, and outlet-passages communicating with said corrugations, a filter-cloth, and a perforated plate covering said corrugations, of a drum mounted to turn in said casing, pockets in said drum having corrugations, means for conducting material to said pockets, and means for ejecting the solid material therefrom, substantially as described.

706,371. STRETCHER. FRANCIS X. AIGNER, Jersey City, N. J. Filed Dec. 30, 1901. Serial No. 87,710. (No model.)



Claim.—1. In a stretcher, a body consisting of two sections arranged to overlap, the overlapping portion of the under section having openings extending through from face to face, and the corresponding portion of the upper section being provided with loops on its under face, and a tie-strip interlaced through said openings and loops, as set forth.

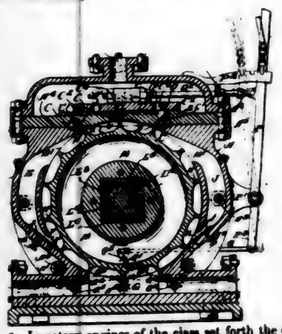
2. In a stretcher, a body consisting of two sections arranged to overlap and provided with registering openings in their overlapping portions, a flexible strip removably interlaced through the said openings, and a blanket attached to the upper face of each of the sections of the body, the blankets abutting at the central portion of the stretcher for the purpose described.

3. In a stretcher, a body consisting of two sections arranged to overlap, the overlapping portion of the under section having openings extending through from face to face, the corresponding portion of the upper section being provided with a hem and the under member of the hem having loops formed therein, the inlets and outlets of which loops are in registry with the openings in the under section, and a tie-strip interlaced through the openings and passed through the loops, as specified.

4. In a stretcher, a pliable body constructed in two overlapping sections having registering eyelets, and a strip of strong belting laced through the eyelets, the ends of the belting-strip being free, whereby the sections of the body are detachably held together even when the stretcher is heavily weighted, and dispensing with the necessity of cross-bars and other fastening devices for the ends of the belting-strip and avoiding tension on the ends of the strip which might be painfully communicated to the patient carried, as described.

5. A stretcher, comprising a body formed of two sections having their inner edges overlapping and provided in the overlapping edges with registering openings, a strip interlaced through said openings, and a folded blanket secured upon each section, the turned edges of the blankets meeting at the center of the body of the stretcher, as set forth.

706,372. ROTARY ENGINE. WILLIAM ALSOP, Newcastle, near Sydney, New South Wales, Australia. Filed June 17, 1901. Serial No. 64,940. (No model.)



Claim.—1. In rotary engines of the class set forth the combination with a driving-disk in a casing, of duplicate initial directing-orifices and duplicate sets of ports and passages with further directing-orifices and with controlling devices so that the direction of travel of the disk may be reversed, substantially as herein described and explained.

2. In rotary engines of the class set forth, the combination with the steam-ports directing-orifices and controlling devices, of additional or auxiliary ports or passages from the initial steam-supply to one or more of further directing-orifices for starting the disk to revolve, substantially as herein described and explained.

3. In a rotary engine, the combination with a driving-disk, of a series of vanes arranged in suitable relation thereto and each provided with an opening, the opening of each alternate vane arranged out of alinement with the opening of the adjacent vane.

4. In a rotary engine, the combination with a driving-disk, of a series of radially-extending vanes formed integral with the disk and each provided with a transversely-extending opening, the opening of one vane being out of alinement with the opening of the adjacent vane.

5. In a rotary engine of the class set forth, a main shaft, bearings therefor, a disk for driving said shaft, resilient packing mounted in oblong orifices for connecting the shaft to the disk, and a series of vanes arranged in suitable relation to said disk and each provided with an opening, the opening of each alternate vane arranged out of alinement with the opening of the adjacent vane.

6. In a rotary engine of the class set forth, a main shaft provided with a squared boss, a driving-disk having an oblong orifice, a box

mounted therein, resilient packing interposed between said box and said shaft, resilient packing interposed between said box and disk, a series of vanes carried by the disk, each provided with a transversely-extending opening, and means for directing a motive fluid to act on and exhaust from said vanes directly and tangentially in the plane of their rotation.

7. In a rotary engine of the class set forth, the combination with a casing and a driving-disk mounted therein, of an initial directing-orifice for the motive fluid to impact with the disk, for imparting movement thereto, a redirecting-orifice for collecting the spent motive fluid to use the same for further impacting with the disk, a passage for establishing communication between the said redirecting-orifice and the disk, and means for regulating the passage of the motive fluid from the redirecting-orifice to the disk.

8. In a rotary engine of the class set forth, the combination with a casing and driving-disk mounted therein, of a series of vanes formed integral with the disk and each provided with a transversely-extending opening, the opening of one vane being out of alinement with the opening of the adjacent vane, an initial directing-orifice for the motive fluid to impact with the said vanes for imparting motion thereto, and means arranged in said casing for collecting the spent motive fluid after its impact with the vanes and then further directing said spent motive fluid against said vanes for causing an additional impulse thereof.

9. In a rotary engine, a drive-disk provided with perforated vanes suitably extending therefrom, the perforation of each alternate vane being out of alinement with the perforation of the adjacent vane, means for initially directing the motive fluid to impact with the said vanes for imparting movement to the disk, and means for collecting the spent motive fluid after its impact with the vanes and for further directing said spent motive fluid against the vanes for causing an additional impulse to the disk.

10. In a rotary engine, a drive-disk provided with perforated vanes suitably extending therefrom, means for initially directing the motive fluid to impact with the said vanes for imparting movement to the disk, means for collecting the spent motive fluid after its impact with the vanes and for further directing said spent motive fluid against the vanes for causing an additional impulse to the disk, means for regulating the passage of the motive fluid from said collecting means to the vanes, and means for reversing the movement of said disk.

11. In a rotary engine of the class set forth, the combination with a casing and driving-disk mounted therein, of an initial directing-orifice for the motive fluid to impact with the said disk for imparting motion thereto, means arranged in said casing for collecting the spent motive fluid after its impact with the disk and for further directing said spent motive fluid against said disk for causing an additional impulse thereof, means for regulating the passage of the motive fluid from said collecting means to the disk, and means for reversing the movement of said disk.

12. In a rotary engine of the class set forth, the combination with a casing and driving-disk mounted therein, of an initial directing-orifice for the motive fluid to impact with the said disk for imparting motion thereto, means arranged in said casing for collecting the spent motive fluid after its impact with the disk and for further directing said spent motive fluid against said disk for causing an additional impulse thereof, means for regulating the passage of the motive fluid from said collecting means to the disk, means for reversing the movement of said disk, and a valve mechanism for exhausting the motive fluid.

13. In a rotary engine of the class set forth, the combination with a casing and a drive-disk mounted therein, of means for initially directing the motive fluid to impact with the said disk for imparting movement thereto, means arranged in said casing for collecting the spent motive fluid after its impact with the disk and for further directing said spent motive fluid against said disk for causing an additional impulse thereto, means for regulating the passage of motive fluid from said collecting means to the disk, a valve mechanism for exhausting the motive fluid from said casing, and means for reversing the movement of said disk, causing thereby the simultaneous reversing of the exhausting valve mechanism.

14. In a rotary engine of the class set forth, a drive-disk mounted in a suitable casing, means for supplying motive fluid to said disk for operating the same, means arranged in the casing for collecting the spent motive fluid after its impact with the disk and for further directing said spent motive fluid against the disk for causing an additional impulse thereof, means for regulating the passage of the motive fluid from said collecting means to the disk, a valve mechanism for exhausting the motive fluid from said casing, and means for reversing the supply of motive fluid to the disk causing a different movement to be imparted thereto and for simultaneously reversing the exhaust valve mechanism.

15. In a rotary engine, the combination with the casing and a driving-disk arranged therein, of means to permit of a motive fluid impacting with the disk for operating the same, means arranged in said casing for collecting the spent motive fluid, a passage for establishing communication between said collecting means and the disk, and means arranged in said passage for regulating the flow of the spent motive fluid from the collecting means to the disk and to permit of the spent motive fluid impacting with the disk for imparting additional impulses to the disk.

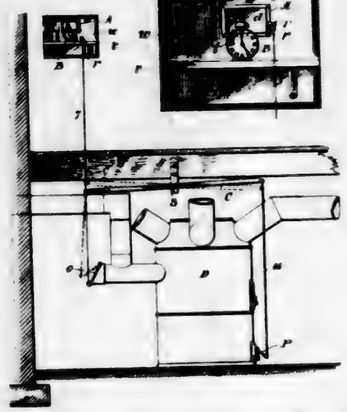
16. In a rotary engine, the combination with the casing and a disk arranged therein, of means for operating the same, means arranged in said casing for collecting and causing the spent motive fluid to impact with the disk for giving additional impulses thereto, means for regulating the impact of the said spent motive fluid, a valve mechanism for exhausting the motive fluid from the casing, and means for reversing the movement of the disk and for simultaneously reversing the exhaust valve mechanism.

17. In a rotary engine, the combination with the casing, of a disk mounted therein and provided with perforated vanes, a valve mechanism for admitting motive fluid to impact with the said vanes for operating the disk, means for collecting the spent motive fluid and for causing the same to impact with the vanes obtaining thereby additional impulses for the disk, means for regulating the impacting of the motive fluid to the disk, a valve mechanism for exhausting the motive fluid from the casing, and means for simultaneously operating said inlet and exhaust valve mechanisms causing thereby a reverse operation of the disk.

18. In a rotary engine, the combination with a driving-disk, of a series of vanes arranged in suitable relation thereto and each provided with an opening, the opening of each alternate vane arranged out of alinement with the opening of the adjacent vane, and means for directing a motive fluid to act on and exhaust from the said vanes directly and tangentially in the plane of their rotation.

19. In a rotary engine, the combination with a driving-disk, of a series of radially-extending vanes formed integral with the disk and each provided with a transversely-extending opening, the opening of one vane being out of alinement with the opening of the adjacent vane, and means for directing a motive fluid to act on and exhaust from the vanes directly and tangentially in the plane of their rotation.

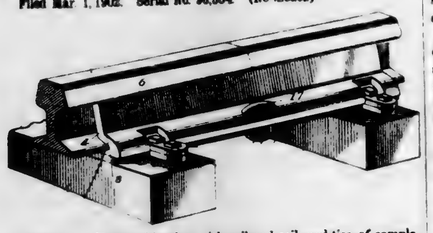
706,373. TIME DAMPER MECHANISM. GEORGE E. ARCHER, Nutley, N. J. Filed Mar. 4, 1902. Serial No. 96,637. (No model.)



Claim.—1. In an automatic furnace-draft controlling apparatus of the class herein described the tripping device comprising the fulcrumed angle-lever with arms *a* and *g*, sliding arm *k*, and a fulcrumed angle-lever having arms *n* and *p*; the said arms *g* and *k* being beveled and notched and adapted to slide over each other and interlock, in combination with a balanced rocker C connected at one end with the smoke-pipe draft and at the opposite end with the ash-pit door, a cord attached at its lower end to one end of the balanced rocker and having a ring at the upper end adapted to rest on and readily slip from the horizontal tipping arm *p* of the tripping device, and a clock mechanism adapted to be set to actuate the tripping device at a given time and cause the tipping arm *p* to drop, substantially as and for the purpose shown and described.

2. The combination with a clock mechanism of a tripping device comprising a lever with an operating-arm *a* connected with the clock, and a locking-arm *g* having a notch *i* and beveled tip, a slidably-mounted arm *k* having a notch to engage the notch *i*, the guide for said arm, and a lever having arms *n* and *p*, one of which is coupled to the sliding arm *k*, substantially as shown and described.

706,374. RAIL-JOINT. HORACE O. BALDWIN, New Brighton, Pa.; Mary E. Baldwin administratrix of said Horace O. Baldwin, deceased. Filed Mar. 1, 1902. Serial No. 96,334. (No model.)

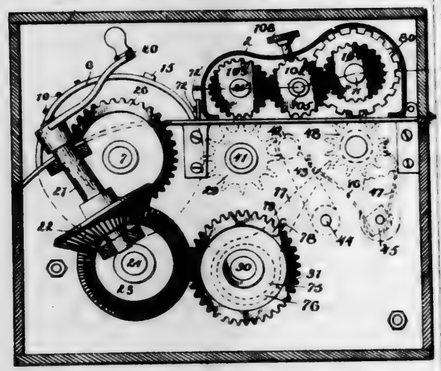


Claim.—1. The combination with railroad rails and ties, of complementary clamping members having overlapped base-flanges and oppositely-extending pairs of overlapped arms, the members having upwardly and inwardly extending flanges bearing against the opposite sides of the rails and one provided with slots therethrough above its base-flange and the other having openings in alinement with its base-flange through which a portion of the arms projects, and fastenings passed through the opposite pairs of overlapping arms and driven into the ties.

2. In a device of the class set forth, the combination with railroad rails and ties, of complementary clamping members having overlapping base-flanges with outwardly-extending pairs of overlapping arms, the arms at one side of each base-flange extending through openings in the other member, and fastening devices passed through the overlapping arms and extending into the ties.

3. In a device of the class set forth, the combination with railroad rails and ties, of complementary clamping members having overlapped base-flanges and oppositely-extending pairs of arms, the flanges having openings therein for the insertion therethrough of a portion of the arms, said openings being located above the base-flange of one member and in alinement with the similar flange of the other member, fastenings passed through the overlapped arms, and a key removably inserted through the base-flanges at one side at a point between the ties.

706,375. CALCULATING-MACHINE. FRANK S. BALDWIN, Newark, N. J. Filed Nov 26 1901. Serial No. 83,741. (No model.)



Claim.—1. A calculating mechanism including twelve-toothed intermediate wheels, registering-wheels and carrying members adapted to engage respectively the upper and lower sides of said intermediate wheels, an actuating mechanism adapted to engage one side and check members engaging the opposite sides of said intermediate wheels, for the purpose described.

2. A calculating mechanism including registering-wheels, actuating members, a plurality of independent intermediate wheels engaging respectively the registering-wheels and the actuating members, a shaft adapted to rotate in the opposite direction, the said shaft provided with a plurality of carrying members constructed and arranged to engage an actuating intermediate gear when the shaft is moved in either direction, substantially as described.

3. A calculating mechanism including registering-wheels, actuating members, a plurality of independent intermediate wheels engaging in operation respectively the registering-wheels and the actuating members, the actuating members adapted to be moved in two directions, a member adapted to move in two directions and carrying a plurality of actuating members arranged in spiral relation, the carrying members constructed and arranged to engage and actuate the intermediate wheels when the carrying members are moved in either direction, substantially as described.

4. A calculating mechanism including registering-wheels, intermediate wheels in engagement therewith, toothed actuating members, and a plurality of carrying members arranged around a common center and actuated independently of the actuating members and said intermediate wheels, the pitch of the teeth of the intermediate wheels and the actuating member being less than the pitch of the arrangement of the carrying members, whereby the teeth of the intermediate wheels revolve slightly in lead of the carrying members, substantially as and for the purpose described.

5. A calculating mechanism including a plurality of registering-wheels, a plurality of independent intermediate wheels in engagement therewith, a plurality of toothed actuating members adapted to engage the intermediate wheels, a plurality of carrying members each carrying member adapted to act in two directions, sliding members between the intermediate wheels and adapted to be actuated by the registering-wheels, and moved in the path of travel of the carrying members and to throw them into engagement with the succeeding intermediate wheel when they are moved in either direction, substantially as described.

6. A calculating mechanism including registering-wheels, a plurality of intermediate wheels in engagement therewith, a plurality of toothed actuating members adapted to engage the intermediate wheels, a plurality of sliding bars adapted to slide transverse the intermediate wheels and actuated by the movement of the registering-wheels, and a plurality of oscillating carrying members adapted to be thrown into action through the medium of the said sliding bars substantially as described.

7. A calculating mechanism including registering-wheels, a plurality of intermediate wheels in engagement therewith, a plurality of toothed actuating members adapted to engage the intermediate wheels, and a revolving member carrying a plurality of oscillating carrying members, and means controlled by the registering-wheels adapted to throw the carrying members into action, substantially as described.

8. A calculating mechanism including a plurality of registering-wheels, a plurality of intermediate wheels in engagement therewith, a plurality of toothed actuating members adapted to engage the intermediate wheels, a revolving member carrying a plurality of oscillating carrying members adapted to engage the intermediate wheels when the revolving member is moved in either direction, and means controlled by the registering-wheels adapted to throw the carrying members into action in either direction, substantially as described.

9. A calculating mechanism including registering-wheels, intermediate wheels, in engagement therewith, toothed actuating members adapted to engage the intermediate wheels, and a revolving member carrying a plurality of independently-acting carrying members, the said carrying members arranged thereon in double oppositely-spiral arrangement, substantially as and for the purpose described.

10. A calculating mechanism including registering-wheels, actuating mechanism and intermediate connections between the actuating mechanism and the registering-wheels, and carrying elements adapted to engage the intermediate mechanism, the carrying elements including a transversely-movable bar, two connected oscillating members one adapted to be engaged by the bar, and the other adapted to engage the succeeding intermediate wheel, substantially as described.

11. A calculating mechanism including registering-wheels, actuating mechanism, intermediate mechanism between the actuating mechanism and the registering-wheels, and a carrying mechanism including a revolving member carrying a plurality of carrying members, a plurality of sliding bars, the carrying members adapted to be oscillated in opposite directions by the sliding bars and consisting each of an approximately cross-shaped member for engagement with the sliding bar, and a shouldered member for engagement with the intermediate mechanism, substantially as described.

12. A calculating mechanism including registering-wheels, actuating mechanism, intermediate mechanism between the actuating mechanism and the registering-wheels, and a carrying mechanism including transversely-movable bars, a revolving member carrying a plurality of oscillating carrying members, each oscillating carrying member having a limited oscillating movement and provided with means to hold it normally in the position to operate in two directions, through engagement with the sliding bars, substantially as described.

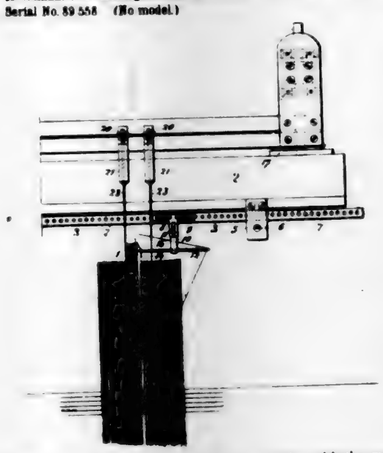
13. A calculating-machine including two series of registering-wheels, and a wiping-out mechanism consisting of an intermediately-arranged oscillating member provided with oppositely-projecting arms adapted to engage projections respectively upon said series of wheels according to the direction in which the oscillating member is moved, and a handle adapted to rotate the series of wheels, whereby the calculation upon either of the series can be independently wiped out, substantially as described.

14. A calculating mechanism including registering-wheels, actuating mechanism, intermediate mechanism, a carrying mechanism, operatively connected with the actuating mechanism, a lever, an eccentric operated by the carrying mechanism, the free end of the eccentric-lever adapted to engage intermediate gears, and a second series of registering-wheels adapted to be actuated by said intermediate gears, substantially as described.

15. A calculating mechanism including a plurality of registering-wheels, a plurality of intermediate wheels, an actuating mechanism, a carrying mechanism, a plurality of independent levers forming checks respectively for the intermediate wheels, an oscillating member carrying a plurality of independent springs adapted to engage the said independent levers, and means for adjusting the oscillating member and thus controlling the tension of the spring and consequently the tension of the checks, substantially as described.

16. In a calculating-machine, a series of registering-wheels alined loosely upon a shaft, and non-shouldered friction devices frictionally connecting said wheels with said shaft.

706,376. LOOM. FRÉDÉRIC BARLET, St. Etienne, France, assignor to William T. P. Hollingsworth, Paterson, N. J. Filed Jan. 13, 1902. Serial No. 89,558. (No model.)



Claim.—1. In a shuttle-loom, and in combination with the means for weaving the body fabric, provisions for forming upon one of the lifts of the main or ground shed an auxiliary or supplemental shed, a needle mounted on and movable lengthwise of the lay and adapted to insert an auxiliary-weft thread into said supplemental shed, and a weft-loop retaining-needle also mounted on the lay and reciprocating thereon in a path transverse to that of the weft-inserting needle and adapted to yield toward the reed and the edge of the warp, substantially as and for the purposes hereinbefore set forth.

2. In a combined shuttle and needle-loom substantially as described, the combination with the batten and the reed, of a double-ended horizontal weft-inserting needle adapted to receive an independent weft-thread at each end, said needle being mounted on and reciprocating lengthwise of the batten, and flexible oscillating weft-loop retaining-needles mounted on the lay and reciprocable thereon in a path transverse to that of the double-ended horizontal needle, substantially as and for the purposes hereinbefore set forth.

706,377. EXTENSION STOVE-LEG. JAMES BARBER, Columbus, Ga. Filed July 27, 1901. Serial No. 69,966. (No model.)

Claim.—The combination with a stove-leg, of a tube or sleeve integral therewith, said tube or sleeve being slotted longitudinally and having bayonet-slots arranged alternately upon opposite sides of the longitudinal slot and communicating therewith, a footpiece having a rod extending upwardly therefrom, said rod being of a length greater than the length of the tube, and the laterally-projecting lug arranged at the upper end of said rod, substantially as described.

706,378. FILE-HANDLE. PHILIPP BENDER, Dotzheim, near Wiesbaden, Germany, assignor to Firm Carl Bender I. Dotzheim, near Wiesbaden, Germany. Filed May 1, 1902. Serial No. 105,562. (No model.)

Claim.—A file-handle provided on its upper end with windings of a material which shrinks when moistened with water, substantially as described and for the purpose set forth.

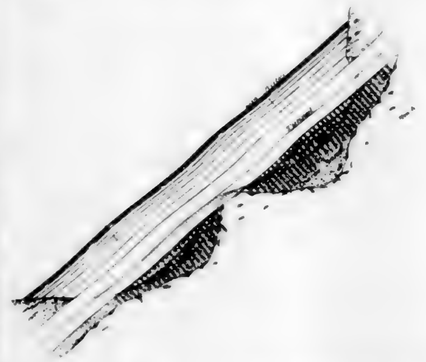
706,379. GEM-SETTING. ROBERT S. BIEBER, Brooklyn, N. Y. Filed Mar. 27, 1902. Serial No. 100,239. (No model.)

Claim.—1. In a gem-setting and in combination with a gem having converging sides or facets forming laterally-projecting edges, a band arranged on said converging sides of the gem above the projecting edges thereof as shown, and means forming a part of the gem-seat adapted to engage the said band substantially as described.

2. In a gem-setting and in combination with the fingers thereof, a band arranged on the gem between it and said fingers, the gem resting on its seat, as common, and the fingers bent over the band substantially as described.

3. In a gem-setting and in combination with a gem having converging sides or facets forming laterally-projecting edges, a band angular in cross-section arranged upon said converging sides of the gem above the projecting edges thereof as shown, and means forming a part of the gem-seat adapted to engage the said band substantially as described.

706,380. METHOD OF CONSTRUCTING TUNNELS. JULES BREUCHAUD, Yonkers, N. Y. Filed Feb. 24, 1902. Serial No. 95,330. (No model.)



Claim.—1. The method of constructing subaqueous tunnels which consists in building progressively an artificial foundation in the bed of the river where needed, then building a portion of the base or bottom of the tunnel upon said foundation in advance of the head of the tunnel, and in then progressively building forward the sides and top of the tunnel.

2. The method of constructing subaqueous tunnels which consists in inserting piling in the bed of the river where needed, in building thereupon a portion of the base of the tunnel to be constructed, and in then building forward on said base portion the sides and top of the tunnel.

3. The method of constructing subaqueous tunnels which consists in first adjusting or placing a movable pneumatic shield in position, in afterward building a foundation in the bed of the river from within the movable shield and in then building a forward extension to the tunnel within said shield.

4. The method of constructing a subaqueous tunnel which consists in first adjusting or placing a movable pneumatic shield in position, in afterward building in the river-bed a suitable foundation for the tunnel

and from within the movable pneumatic shield, in then building an extension to the tunnel within the shield, and in then moving the shield forward for the construction of additional foundation and tunnel.

5. The method of constructing a subaqueous tunnel which consists in first adjusting or placing a movable pneumatic shield in position, in afterward building in the river-bed a suitable foundation for the tunnel and from within the movable pneumatic shield, in then building an extension to the tunnel within the shield, in then ejecting jets from the head of the shield and removing or displacing material in advance thereof and in then forcing the shield forwardly over said foundation.

6. The method of constructing subaqueous tunnels which consists in first adjusting or placing a movable open-bottom pneumatic shield in position, in afterward inserting piling into the bed of the river from within the open bottom of said pneumatic shield, in then building a portion of the bottom of the tunnel upon said piling and within said shield, in then building extensions of the sides and top of the tunnel within said shield, in then moving the shield forwardly over said bottom portion of the tunnel, and in then successively repeating said operations where necessary.

7. The method of constructing subaqueous tunnels which consists in first adjusting or placing a movable open-bottom pneumatic shield in position, in afterward inserting piling into the bed of the river from within the open bottom of said pneumatic shield, in then building a portion of the bottom of the tunnel upon said piling and within said shield, in then building extensions of the sides and top of the tunnel within said shield, in then displacing or removing material from in front of the shield in then forcing the shield forwardly over the said bottom of the tunnel and in then repeating the several operations where needed.

8. The method of constructing a subaqueous structure which consists in first adjusting or placing a longitudinally-movable pneumatic shield in position, in afterward building a foundation from within said shield, in then building an extension of such structure upon such foundation, in then advancing the shield, and in then repeating the operations wherever needed.

9. The method of constructing subaqueous structures, which consists in first adjusting or placing a longitudinally-movable open-bottom pneumatic shield in position, in afterward inserting piling into the river-bed from within the open bottom of said shield, in then building from within said shield a flooring or covering upon such piling, and thereby extending the said structure longitudinally, and in then moving the shield forwardly in the line of the structure so as to enable the several operations to be repeated.

10. The method of constructing a subaqueous tunnel which consists in first adjusting or placing a movable pneumatic shield in position, in then inserting piling into the bed of the river from within said shield and in advance of the tunnel, in then building a flooring or covering upon said piling from within said shield, in then building extensions of the sides and top of the tunnel within said shield, and in then advancing the shield horizontally to enable the said several operations to be repeated.

706,881. BANJO ATTACHMENT. HOWARD M. BROWSON, Brandon, Vt. Filed Nov. 21, 1901. Serial No. 83,135. (No model.)

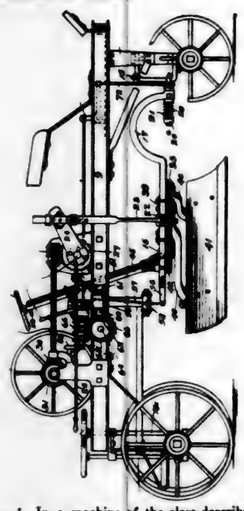
Claim.—1. The combination with a cross-bar of a banjo, or similar musical instrument, of a lever resting on said bar, yieldable members connected to said lever, a coupling coöperating with said members in holding said lever in operative position on said cross-bar, and a muffler carried by said lever.

2. A muffling attachment for banjos and other musical instruments, comprising a lever provided with an offstanding arm, a muffler adjustably fitted to said arm and shiftable to different positions lengthwise thereof, means for holding said muffler in different positions on the arm, suitable attaching devices for the lever, and an operating device.

3. A banjo attachment, comprising a lever terminating at one end in an angular handle carrying a knob and terminating at its other end in a loop, a return bent arm having an upright stem, elastic bands attached to the said loop and having a connection engaging the under side of the cross-brace, and a muffler secured on the said stem, for engaging the head of the instrument, as set forth.

4. A banjo attachment comprising a lever terminating at one end in an angular handle carrying a knob and terminating at its other end in a loop, a return bent arm having an upright stem, elastic bands attached to the said loop and having a connection engaging the under side of the cross-brace, a muffler secured on the said stem, for engaging the head of the instrument, and a guide on the side of the cross-brace for the angular handle to slide in, as set forth.

706,882. ROAD-GRADING MACHINE. ROBERT H. BURKE, Anderson, Ind., assignor to M. B. Wilson, Chicago, Ill. Filed Dec. 2, 1901. Serial No. 84,370. (No model.)



Claim.—1. In a machine of the class described, the combination with the main longitudinally disposed blade-supporting bars, of an externally-toothed circle-plate disposed therebeneath and having the scraper-blade pendent therefrom, a plurality of intersecting supporting-bars hung from said main longitudinal bars and disposed transversely of the circle-plate and at their outer ends supporting the latter, and a pinion engaging the toothed periphery of the circle-plate and operating means for said pinion, substantially as described.

2. In a machine of the class described, the combination, with the main longitudinally-disposed blade-supporting bars, of an externally-toothed circle-plate disposed therebeneath and having the scraper-blade pendent therefrom, a plurality of intersecting supporting-bars hung from said main longitudinal bars and disposed transversely of the circle-plate, said bars being vertically offset through their main body portions which lie within the circle-plate diametrically thereof and having their end portions underlying said circle-plate and forming both a support and a centering-guide therefor, and a pinion engaging the toothed periphery of the circle-plate and operating means for said pinion, substantially as described.

3. In a machine of the class described, the combination with the scraper-blade and its immediate supporting-frame, of means for effecting the vertical adjustment of said frame from the operator's platform, said means including as elements thereof a transverse shaft, arms on said shaft from which the blade-supporting frame is suspended, worm-gears on said shaft and worms for operating the same, and clutch mechanisms intermediate said arms and worm-gears and levers for operating said clutches, whereby the arms may be maintained in rotative engagement with the gears or may be freed therefrom to permit the blade to drop suddenly, substantially as described.

4. In a machine of the class described, the combination, with the scraper-blade of a pair of longitudinally-disposed main supporting-bars therefor suspended from and beneath the main frame of the machine, the rear ends of said main supporting-bars having end sections pivoted thereto in vertical planes, and means for vertically adjusting said blade and its supporting-bars relatively to the main frame of the machine in which adjustment said pivoted sections yield downwardly to permit the extreme upward movement of the blade and its bars without interference with fixed elements of the main machine-frame, substantially as described.

5. In a machine of the class described, the combination with the main frame of the machine and the scraper-blade and the two longitudinally-disposed and rearwardly-divergent supporting-bars therefor suspended from the main frame, of means for adjusting said blade and its supporting-bars laterally of the machine-frame, said means comprising a pair of drums journaled adjacent and parallel with the principal side members of the machine-frame and supported by the latter, chains attached to the rear ends of the blade-supporting bars and carried thence over suitable guides to and around the drums on the sides of the machine-frame respectively, a shaft extending transversely of the main frame, bevel-gears fast on the ends of said shaft, bevel-pinions on the adjacent ends of the drum-shafts and engaging said bevel-gears, and a worm-gear and operating devices therefor engaging and driving said transverse shaft, substantially as described.

6. In a machine of the class described, the combination, with the longitudinally-disposed main supporting-bars, the intersecting circle-plate-supporting bars suspended therefrom and the toothed circle-plate and its attached scraper-blade supported and centered by said last-named bars, said circle-plate having a series of locking-apertures formed therethrough, of a driving-pinion for rotating said circle-plate supported on the main longitudinal bars and a vertically-reciprocable spring-actuated locking-pin also supported on said bars directly above the path of travel of said locking-apertures and adapted to engage the latter, and means for withdrawing said locking-pin, the same comprising a spiral cam-surface axially coincident with the locking-pin and a laterally-projecting lug on the latter engaging said cam-surface to raise the pin out of locking engagement with the circle-plate, substantially as described.

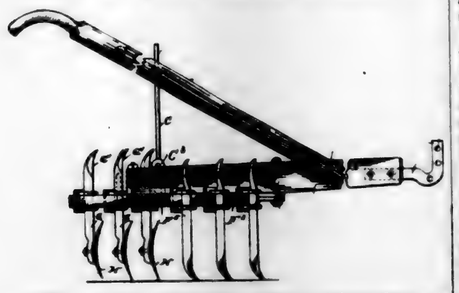
7. In a machine of the class described, the combination, with the main carrying-frame and the blade-supporting frame suspended therefrom and longitudinally disposed therebeneath, and mechanism for quickly elevating the forward end of the blade-supporting frame in order to enable the blade to surmount an obstruction, said mechanism comprising a hand-lever and segment-rack therefor mounted on the main frame, and rod and lever connections therefrom to the forward end of the underlying blade-supporting frame, substantially as described.

8. The combination with the longitudinal side members of the main frame of a pair of upstanding bracket-plates bolted thereto on opposite sides of the machine, said plates being vertically slotted near their upper ends, a transverse shaft journaled in and between said bracket-plates below the slots thereof and carrying worm-gears on the outer ends thereof, worms and supporting-brackets therefor, the stems of which latter extend through the slots of the bracket-plates, a pair of intersecting diagonally-disposed brace-rods uniting the shank of each worm-bracket with the base of the opposite bracket-plate, and lock-nuts for adjusting said brace-rods longitudinally and through the latter adjusting the relation of the worms to their gears, said parts being assembled and operating substantially in the manner described.

9. The combination with the side channel-beam of the main frame and a filling-block interposed therein of a bracket secured thereon adapted to form a support for coöperating elements of the blade-adjusting mechanism, said bracket comprising a pair of upwardly-divergent side plates bolted at their lower ends on opposite sides of the channel through the web of the latter and the filling-block, a horizontal U-shaped brace uniting the upper ends of the side plates, and upstanding journal-blocks secured on the upper ends of the side plates and on the transverse element of the U-shaped brace, said bearing-blocks constituting journals for a pair of shafts disposed at right angles and carrying intermeshing bevel-pinions constituting elements of the blade-adjusting mechanism, substantially as described.

10. In a road-machine of the character indicated, the combination with a rear axle formed in two overlapping extensible bar-sections having longitudinal grooves in their outer faces respectively, of a housing for said axle-sections, the same comprising four angle-bars slidingly engaged by the outer corners of the axle-sections and top and bottom and front and rear plates rigidly tying together said angle-plates, a series of anti-friction-rollers journaled in said top and bottom plates between the inner opposite faces of the axle-bars and engaging the latter in rolling contact, and means for adjusting the axle-bars longitudinally of each other comprising racks secured in the grooves of the bars and pinions engaging said racks, substantially as described.

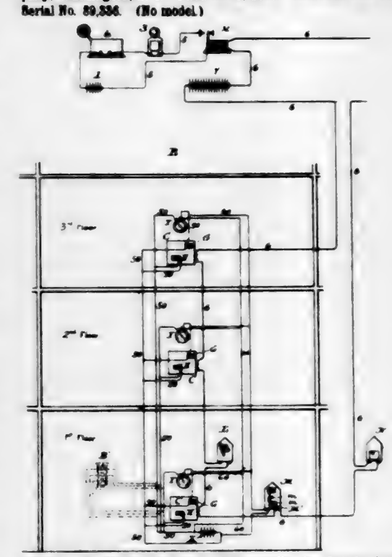
706,883. CULTIVATOR. WILLIAM F. CARSON, Skinnersville N. C. Filed Aug. 19, 1901. Serial No. 72,605. (No model.)



Claim.—1. The combination in a cultivator of the tooth-supporting frame-bar, the clamping-block having an upright curved groove for the tooth, and provided at its opposite ends with lugs or ears to overlap the frame-bar, and at such ends with grooves for the clamping-bolts, the tooth, and the U-shape clamping-bolts fitting around the tooth and in the grooves of the clamping-block, and securing the tooth and clamping-blocks in connection with the frame-bar, substantially as set forth.

2. In a cultivator, the combination of the beam, the handles, the keeper-box applied to the beam near its rear end, the bolts securing the said keeper-box to the beam, the handle-supporting stand bold to the beam by one of said bolts, means securing the handles to the upright portions of said stand, the tooth-supporting frames having at their rear ends portions fitting within the keeper-box, and clamp devices for securing said portions in the keeper-box, substantially as set forth.

706,884. FIRE-ALARM-TELEGRAPH SYSTEM. ROBERT G. CALLUM, Washington, D. C., assignor to the Callum Fire Signal Company, Washington, D. C. Filed Oct. 5, 1899. Renewed Jan. 11, 1902. Serial No. 89,336. (No model.)



Claim.—1. The combination of a normally closed main electric circuit, a fire-alarm box included in said circuit, successively-acting signal-transmitting instruments operated by clock-trains, a controlling-electromagnet, a closed local electric circuit, an open local electric circuit, and a thermostat adapted to open the closed circuit through said electromagnet and release the clock-trains when the temperature reaches a predetermined degree of heat, and close the open circuit through the fire-alarm box when the temperature reaches a predetermined higher degree of heat, substantially as set forth.

2. In a fire-alarm system, the combination of a normally closed main electric circuit, a fire-alarm box, and an automatic signal-transmitting instrument included in said circuit, an electromagnet, G, for controlling the signal mechanism of the transmitting instrument, a thermostat, a local battery, a closed circuit from the local battery through the magnet, G, and the thermostat, and an open circuit from said local battery through the fire-alarm box and the thermostat, substantially as set forth.

3. In a fire-alarm system, the combination of a normally closed main circuit, a fire-alarm box, and a signal-transmitting instrument included in said circuit, an electromagnet, G, in said transmitting instrument, a thermostat, a local battery, a closed circuit from the local battery through the magnet, G, and the thermostat, an open circuit from local battery through the fire-alarm box, and the thermostat, a battery signaling instrument also on the main circuit, and a second closed circuit from the local battery through the battery signaling instrument, substantially as set forth.

4. In a fire-alarm system, the combination of a normally closed main electric circuit, a fire-alarm box and an automatic signal-transmitting instrument operated by clock-train, included in said circuit, a closed local circuit containing an electromagnet for tripping the clock-train, a battery, a thermostat adapted to open the closed local circuit when the temperature reaches a predetermined degree of heat, an open circuit from said battery to the fire-alarm box, which circuit is closed when the temperature reaches a predetermined higher degree of heat and trips the mechanism in said fire-alarm box, and a separate instrument on the main circuit

adapted to transmit thereover an arbitrary signal when the local battery fails, substantially as set forth.

5. In a fire-alarm system, in combination with a normally closed main circuit, including signal-receiving instruments, successively-acting signal-transmitting instruments, an independent, automatic signal-transmitting instrument and manually and electrically operated fire-alarm-signaling instruments, a battery, a closed circuit from battery to the electromagnet of the successively-acting signal-transmitting instruments, an open circuit from said battery to the electrically-operated fire-alarm-signal instrument, a thermostat adapted to open the closed and close the open circuits, and a second closed circuit also from said battery to the magnet of the independent, automatic signal-transmitting instrument, substantially as set forth.

6. In a fire-alarm system, successively-acting signal-transmitting instruments, each operated by a clock-train, a circuit-breaking disk adapted to be rotated by each clock-train, means for arresting the movement of each clock-train, an electromagnet in a closed circuit adapted to release one of the clock-trains when the circuit is broken, a battery in the closed circuit, an independent signal-transmitting instrument containing a clock-train, a rotatable disk, and means for stopping the clock-train, an electromagnet in a second closed circuit from the battery, and mechanism for releasing the independent signal-transmitting instrument and arresting the movement of the successively-acting signal-transmitting instruments when the circuit through the last-named magnet is broken, substantially as set forth.

7. In a fire-alarm system, successively-acting signal-transmitting instruments, an independent signal-transmitting instrument, a circuit-breaking disk on each instrument rotated by clockwork, means for arresting the movement of each circuit-breaking disk, a thermostat, an electromagnet on a closed electric circuit adapted to be broken by the movement of the thermostat for releasing the first of the successively-acting signal-transmitting instruments, a battery in the closed circuit, an electromagnet energized by a second closed circuit from the battery, means controlled by said electromagnet for alternately releasing and arresting the operation of the successively-acting and independent signal-transmitting instruments, and a normally closed main circuit passing through the several circuit-breaking disks, substantially as set forth.

8. In a fire-alarm system, successively-acting signal-transmitting instruments, rotatable circuit-breaking disks thereon, a battery, an electromagnet for arresting the operation of the circuit-breaking disks while the circuit remains unbroken, a normally closed main circuit through said signal-transmitting instruments, a second electromagnet in a closed circuit from the battery, and means in the normally closed main circuit for sending an arbitrary signal therethrough should the battery become inoperative, substantially as set forth.

9. In a fire-alarm system, the combination of a normally closed main circuit, signal-receiving instruments therein at a central office, signal-transmitting instruments also in the normally closed main circuit in various parts of a building to be protected, a local battery, closed local circuits, controlling through the movement of thermostats the operation of each signal-transmitting instrument, and means in the normally closed main circuit for transmitting an arbitrary signal to the central office when the local battery fails, substantially as set forth.

10. A signal-transmitting instrument provided with an electromagnet, a battery, a circuit from the battery through said electromagnet, a second signal-transmitting instrument also provided with an electromagnet, a second or shunt circuit from aforesaid battery to the second electromagnet, and means for locking against movement the first-mentioned signal-transmitting instrument while the second instrument is in operation.

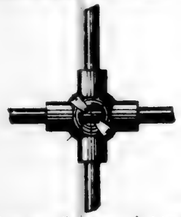
11. A signal-transmitting instrument operated by clockwork and provided with an electromagnet and a circuit-breaker, a thermostat, a battery, a closed local circuit from the battery through the electromagnet and the thermostat, a second signal-transmitting instrument similar to the first, a second closed circuit from the aforesaid battery to the magnet of the second signal-transmitting instrument, and a normally closed main circuit passing through the circuit-breakers of the two instruments, substantially as set forth.

12. A signal-transmitting instrument operated by clockwork and provided with an electromagnet and a circuit-breaker, a thermostat, a battery, a closed local circuit from the battery through the said electromagnet and the thermostat, a second signal-transmitting instrument operated by clockwork also provided with an electromagnet, and a circuit-breaker, a closed local circuit from the aforesaid battery to the second electromagnet, means for locking against movement the first-mentioned signal-transmitting instrument when the second instrument is in operation, and a main circuit passing through the circuit-breakers.

13. In a fire-alarm system, the combination of a normally closed main electric circuit, a fire-alarm box and an automatic signal-transmitting instrument included in said main circuit, controlling-magnets, M', G, in the fire-alarm box and automatic signal-transmitting instrument respectively, a closed local electric circuit through the magnet, G, an open local circuit through the magnet, M', a battery, and a thermostat through which both local circuits pass, substantially as set forth.

14. In a fire-alarm system, the combination of a normally closed main circuit, a fire-alarm box and a signal-transmitting instrument included in said main circuit, a controlling-electromagnet, M', in the fire-alarm box, a similar magnet, G, in the signal-transmitting instrument, a closed local circuit through the magnet, G, an open local circuit through the magnet, M', a battery and a thermostat through which both local circuits pass, and a battery signaling instrument on the main closed circuit, containing an electromagnet in a closed shunt-circuit from the aforesaid battery, substantially as set forth.

706,885. WIRE-FENCE CLIP. FRANK CANFIELD, Denver, Colo., assignor to the Western Wire Fence Company, Denver, Colo. Filed Nov. 9, 1901. Serial No. 81,737. (No model.)

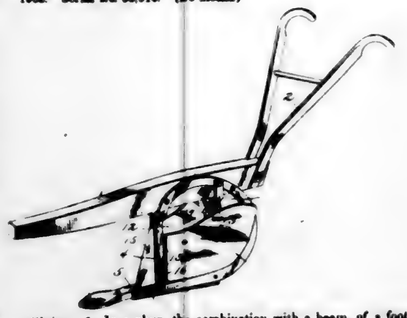


Claim.—1. A fastening-clip composed of two twin members, each having a central part provided with an opening, and projections provided with grooves or recesses, the arrangement being such that when the parts are assembled, the wire and stay cross in the center of the clip, and are bent into the central openings, while the grooved projections form seats for the wire and stay respectively, each member being provided with two arms adapted to embrace the other member, the free extremities of the arms of each member being bent into the openings of the opposite member.

2. The combination with a wire and stay, of a fastening-clip composed of two twin members, each having a central part provided with an opening, and four projections having grooves or recesses communicating with said opening, the arrangement being such that when the parts are assembled, the wire and stay cross each other in the central part of the clip whose members are placed face to face so that their grooves and openings register or coincide, the grooves forming seats for the wire and stay which are bent where they cross, into the openings of the clip members, each member having a fastening-arm adapted to embrace the other member, the free extremities of the fastening-arms being bent into the openings of the opposite clip members.

3. A wire-fence fastening-clip composed of two coöperating members, each having a central part provided with an opening, and four projections having grooves or recesses forming seats for the wire and stay when crossed in the central part of the clip, each member having two arms diagonally arranged and adapted to embrace and clinch the other member, the free extremities of the embracing arms being bent into the openings of the opposite clip members, substantially as described.

706,886. PLOW. OLIVER L. CARMICAL, Monk, Ga. Filed Jan. 6, 1902. Serial No. 88,610. (No model.)



Claim.—1. In a plow, the combination with a beam, of a foot secured thereto, comprising two D-shaped members secured together at their lower ends and engaging the beam on either side, a removable plow-point secured to the forward extremity of said foot.

2. In a plow, the combination with a beam, of a foot comprising a pair of vertically-arranged D-shaped pieces of steel secured to said beam, a pair of parallel vertically-arranged standards secured to said members, a removable wing bolted to said standards and adjustably secured between the same.

3. In a plow, the combination with a beam, of a foot secured thereto, comprising two D-shaped members secured together and engaging the beam on either side, a removable plow-point secured to the forward extremity of said foot and a vertically-arranged knife fastened between the members for the purpose specified.

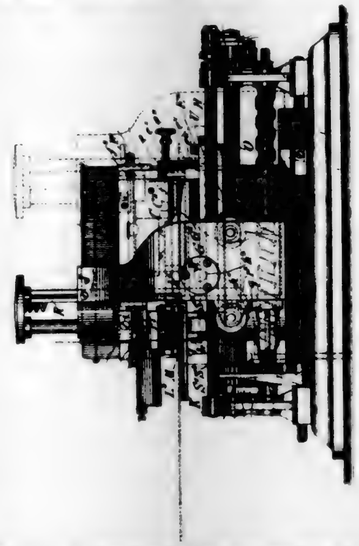
4. In a plow, the combination with a beam; of a foot secured thereto and having two forwardly-projecting lateral extensions at its lower extremity, said extensions being spaced apart, and a removable point secured between the extensions.

5. In a plow, the combination with a beam; of a foot secured thereto and having two forwardly-projecting lateral extensions at its lower extremity, said extensions being spaced apart, and a removable point secured between the extensions, and a removable landside secured to the under side of the foot and terminating adjacent the point.

6. In a plow, the combination with a beam, and a foot secured thereto having a vertical groove in the forward portion thereof, of a pair of standards carried by the foot and arranged parallel to each other, of a vertically-adjustable wing secured to the standards, means interposed between the standards for retaining the wing in its adjusted position, and means carried by the wing for engagement with the slot in the foot.

7. In a plow, the combination with a beam and a vertically-arranged foot carried thereby, of two forwardly-projecting extensions carried by said foot, a removable plow-point secured between the extensions, a removable landside arranged adjacent the point, a pair of standards carried by the foot and vertically-adjustable wings carried by the standards and secured to the foot.

706,887. STAMP DETACHING AND AFFIXING MACHINE. JOHN A. CHAMBLISS, New York, N. Y. Filed July 30, 1900. Renewed Jan. 18, 1902. Serial No. 90,284. (No model.)



Claim.—1. In a stamp detaching and affixing machine, the combination of means for holding a sheet of stamps, a carriage provided with an aperture or throat for receiving the articles to be stamped, means for guiding said carriage, a plunger mounted on the carriage, means for supplying moisture, and means for automatically returning the plunger and for automatically shifting the carriage progressively from one stamp to the next, substantially as set forth.

2. In a stamp detaching and affixing machine, the combination of means for holding a sheet of stamps, means for automatically shifting the sheet progressively, a carriage provided with an aperture or throat for receiving the articles to be stamped, means for guiding said carriage, a plunger mounted on the carriage, means for supplying moisture, and means for automatically returning the plunger and for automatically shifting the carriage progressively from one stamp to the next, substantially as set forth.

3. In a stamp detaching and affixing machine, the combination of means for holding a sheet of stamps, a carriage provided with an aperture or throat for receiving the article to be stamped, means for guiding said carriage, a plunger mounted on the carriage, means for supplying moisture, means for automatically returning the plunger and for automatically shifting the carriage progressively from one stamp to the next, and means for causing the automatic return of the carriage to initial position, substantially as set forth.

4. In a stamp detaching and affixing machine, the combination of means for holding a sheet of stamps, means for shifting the sheet progressively, a carriage provided with an aperture or throat to receive the articles to be stamped, means for guiding said carriage, a plunger mounted on the carriage, means for supplying moisture, means for automatically shifting the carriage progressively from one stamp to the next, and means for causing the automatic return of the carriage to initial position, substantially as set forth.

5. In a stamp detaching and affixing machine, the combination of a platform for supporting a sheet of stamps, means for retaining the stamps, means for automatically shifting the position of the sheet progressively, a carriage having an aperture or throat for receiving the articles to be stamped, a suitably-operated and spring-returned plunger connected to and movable with the carriage for detaching and affixing the stamps, mechanism operated automatically by the plunger for automatically shifting the carriage progressively from one stamp to the next, and means for limiting or determining the extent of such movement, substantially as set forth.

6. In a stamp detaching and affixing machine, a platform for supporting a sheet of stamps, means for automatically shifting the position of the sheet progressively, a carriage having an aperture or throat for receiving the articles to which the stamps are to be affixed, a hand-operated and spring-returned plunger connected to and movable with the carriage for detaching and affixing the stamps, mechanism operated automatically by the plunger for automatically shifting the carriage progressively from one stamp to the next, and means for locking the carriage momentarily to prevent accidental movement, substantially as set forth.

7. In a stamp detaching and affixing machine, the combination of a platform, means for feeding the sheet of stamps forward, a carriage guided transversely of the platform, said carriage comprising a moistener, and means for detaching the stamps and pressing them onto the articles to be stamped, and means for automatically returning the carriage to initial position, substantially as set forth.

8. In a stamp detaching and affixing machine, the combination of a platform, a carriage guided transversely of the platform, and comprising a moistener, a work-table for supporting the articles to be stamped, and means for detaching the stamps and pressing them onto the articles, and means for automatically returning the carriage to initial position, substantially as set forth.

9. In a stamp detaching and affixing machine, the combination of an apertured box, provided with means for feeding a sheet of stamps through its aperture, for use, means for supporting a pile of sheets in the box, and means consisting of a series of pivoted pushers, a pivoted segment protruding through the box, and devices connecting the segment and pushers, said means being adapted for imparting an initial movement to the uppermost sheet in the box for introducing it to the aforesaid feeding means, substantially as set forth.

10. In a stamp detaching and affixing machine, the combination of an apertured box or case, provided with means for supporting a sheet or sheets of stamps therein, a pair of feed rolls arranged in the aperture, one of said rolls being shiftable relatively to the other, automatically-operated gearing for turning said rolls intermittently, and means for adjusting and setting the other roller and said gearing back for producing a certain movement of the rolls, corresponding with the width of a row of stamps, substantially as set forth.

11. In a stamp detaching and affixing machine, the combination of means for holding sheets of stamps, a pair of feed-rolls, gearing for said rolls, such gearing comprising a worm-wheel, a carriage, means for guiding said carriage parallel with said feed-rolls, means on said carriage for successively detaching and affixing the exposed stamps, and a rack-bar fixed to the carriage and meshing with said worm-wheel, substantially as set forth.

12. In a stamp detaching and affixing machine, the combination of means for holding a sheet of stamps, a carriage, means for guiding the carriage, means, mounted on the carriage for detaching individual stamps, means for supplying moisture, a feed-worm suitably geared with said carriage, means for rotating said feed-worm in one direction, and means for reversing the direction of movement of the feed-worm, substantially as set forth.

13. In a stamp detaching and affixing machine, the combination of means for holding a sheet of stamps, a carriage, means for guiding the carriage, means, mounted on the carriage, for detaching individual stamps,

a feed-worm suitably geared to said carriage, means, operated through the stamp-detaching means, for rotating said feed-worm in one direction, whereby the carriage is advanced step by step, means for limiting said advancing motion to correspond with one stamp, and means for automatically reversing the direction of movement of said feed-worm to return the carriage to original position, substantially as set forth.

14. In a stamp detaching and affixing machine, the combination of means for holding a sheet of stamps, a carriage, means for guiding the carriage, means, mounted on the carriage, for detaching individual stamps, a feed-worm suitably geared with the carriage, a spring-barrel, means, operated through the stamp-detaching means, for storing up power in said barrel and for causing the turning of the feed-worm in one direction, and means operated by the spring-barrel for reversing the direction of movement of said feed-worm to return the carriage to original position, substantially as set forth.

15. In a stamp detaching and affixing machine, the combination, of means for holding a sheet of stamps, a carriage, means for guiding the carriage, means, mounted on the carriage, for detaching the stamps, a feed-worm suitably geared with the carriage, a toothed actuating-bar guided in the carriage, a spring-barrel, a toothed or ribbed winding-shaft operated by said actuating-bar and connected with said spring-barrel, means for connecting the latter with the feed-worm for intermittently turning the same in one direction, and means for holding said winding-shaft stationary so that the spring-barrel may impart a reverse movement to the feed worm, substantially as set forth.

16. In a stamp detaching and affixing machine, the combination of means for holding a sheet of stamps, a carriage, means for guiding said carriage, means mounted on the carriage for detaching the stamps, mechanism for advancing said carriage step by step and for automatically returning it to original position, and a shifting device operated by a part connected with the detaching devices on the carriage for causing the automatic return thereof to initial position, substantially as set forth.

17. In a stamp detaching and affixing machine, the combination of means for detaching individual stamps, comprising a plunger, an apertured die-plate through which the plunger passes, and a pivoted yielding work-table upon which the articles to be stamped are placed, substantially as set forth.

706,888. SAVINGS-BANK. JULIUS CHEIN, New York, N. Y. Filed Jan. 3, 1902. Serial No. 88,836. (No model.)

Claim.—1. In a bank the combination of a plurality of counterpart members, a plurality of longitudinal ribs thereon, slots in such longitudinal ribs, and a plurality of separable rings, each provided with an inwardly-projecting flange, substantially as shown and described.

2. In a device of the character described a plurality of separable rings provided with inwardly-projecting notched flanges and a separable cylinder provided with notched ribs, substantially as shown and described.

3. The combination with a coin-holder comprising a pair of longitudinally-slidable semitubular sections forming a cylindrical chamber, of a plurality of rotatable bands inclosing said tubular sections and provided with means for locking and releasing said sections.

4. The combination with a coin-holder comprising a pair of semitubular sections forming a cylindrical chamber, each section provided with a headed portion and a plurality of longitudinally-disposed ribs, having concentrically-alined recesses transversely thereof, of a plurality of locking devices operating in said recesses for locking said sections together

5. The combination with a coin-holder, comprising a pair of longitudinal slidable semitubular sections forming a cylindrical coin-chamber, each section provided with a head and a series of longitudinal and intermitted ribs, of a plurality of rings, rotatable upon said sections provided with means for alternately locking said sections together and permitting them to slide longitudinally, one relatively to the other.

6. In a coin-holder, the longitudinally-slidable tube-sections having heads, the rings forming the exterior of the tube between the heads and rotatable upon said sections, combined with means extending between said sections and said rings for locking and releasing the tube-sections.

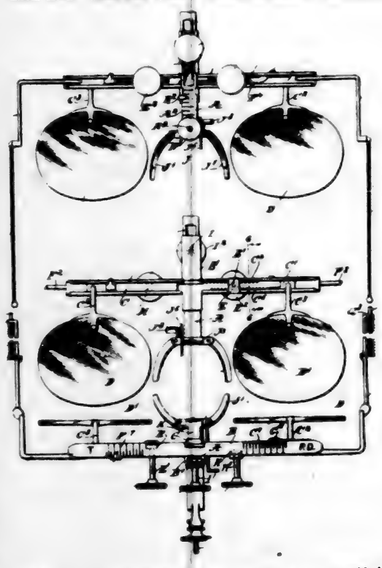
7. In a coin-holder the combination with a pair of semitubular sections forming a cylindrical chamber, each section provided with a headed portion and a plurality of longitudinally-disposed ribs having concentrically-alined recesses transversely thereof, of a plurality of bands incasing said sections, and means on said bands adapted to operate in said recesses and engage said ribs for locking the two sections together.

8. The combination, in a coin-holder, with the tube-sections, each having a head and longitudinally-projecting ribs having concentrically-alined spaces, of a plurality of rings having inwardly extending flanges adapted to move in said rib-spaces, and niches in said flanges permitting said ribs to move longitudinally therein.

9. In a coin-holder the combination with a cylindrical chamber comprising a pair of semitubular sections, each section having a headed portion and provided on their longitudinal edges with ribs forming a sliding connection between said sections, said ribs having concentrically-alined recesses transversely thereof, of a locking device comprising a plurality of rotatable bands incasing said sections and provided with means adapted to operate in said recesses and engage said ribs for locking the two sections together.

10. In a coin-holder, the combination with the tube-sections having guide-forming projections on their longitudinal edges, the edges of one section being received within said groove, spaces in said guide-ribs or projections adapted to be concentrically alined, the said sections having further longitudinal and spaced ribs between said guide-ribs, all the spaces being adapted to be transversely alined, and a plurality of rings encircling said sections and having inwardly-extending flanges laterally rotatable in said spaces, and niches formed in said flanges in which said ribs are longitudinally movable.

706,889. MEASURING DEVICE. CHRISTIAN CHRISTENSEN, Racine, Mich. Filed Dec. 7, 1901. Serial No. 85,006. (No model.)



Claim.—1. A measuring device, comprising a post provided with a longitudinal slot having a rack at one side, a bar having a sleeve mounted to slide up and down on the said post, the said bar being provided with guideways, lens-carriers slidable toward or from each other and lengthwise on the bar, means for sliding the lens-carriers simultaneously temple-carriers slidable toward or from each other and lengthwise on the said bar, means for sliding the temple-carriers simultaneously, an adjustable saddle or crest for the nose supported on said post, and a gear-wheel arranged in the slot in the post and meshing with the rack, the shaft of the gear-wheel being journaled in said sleeve, as set forth.

2. A measuring device, comprising a post, a bar slidable up and down on the post and provided at the front and rear sides with guideways, lens-carriers mounted in the guideway at one side, and slidable, toward or from each other and lengthwise on the bar, means for sliding the lens-carriers simultaneously temple-carriers mounted in the other guideway and slidable toward or from each other and lengthwise of the bar, means for sliding the temple-carriers simultaneously an adjustable saddle or crest for the nose, supported on said post, and means for setting said saddle at a desired angle, as set forth.

3. A measuring device provided with a bar having a longitudinal guideway formed in one of its faces lens-carriers mounted to slide in said guideway toward or from each other and provided with racks, a gear-wheel in mesh at opposite sides with said racks, and means for turning said gear-wheel to move said lens-carriers simultaneously toward or from each other, as set forth.

4. A measuring device provided with a bar having a longitudinal guideway, temple-carriers mounted to slide in said guideway and provided with racks, adjustable temples carried by said temple-carriers, a gear-wheel in mesh at opposite sides with said racks, and means for turning said gear-wheel for moving said temple-carriers simultaneously toward or from each other, as set forth.

5. A measuring device provided with a bar having a guideway, temple-carriers mounted to slide in said guideway and provided with racks, adjustable temples carried by said temple-carriers, a gear-wheel under the control of the operator and in mesh at opposite sides with said racks for moving said temple-carriers simultaneously toward or from each other, a pointer on one of the temple-carriers and a graduation on said bar on which the pointer indicates, as set forth.

6. A measuring device, comprising a post, a bar slidable up and down on the post and provided on its front and rear faces with longitudinal guideways, lens-carriers mounted in the guideway on one face of the bar and slidable toward or from each other, temple-carriers mounted in the other guideway and slidable simultaneously toward or from each other, means for sliding the temple-carriers simultaneously, an adjustable saddle or crest for the nose supported on said post, means for setting said saddle at a desired angle, a pointer on one of the lens-carriers, and a graduation on the said bar on which said pointer indicates to give the pupilary distance of the eyes, as set forth.

7. A measuring device, comprising a post, a bar mounted to slide on said post and having guideways, lens and temple carriers supported in said guideways, means for moving said bar up and down on said post, a pointer moving with said bar, a graduation on said post on which the pointer indicates, a saddle, a bar in which the saddle is pivoted, the said bar being adjustable transversely in a bearing at the lower end of the post, means for turning said saddle on its pivot, and means for adjusting said bar transversely, as set forth.

8. A measuring device, comprising a post, a bar provided with a sleeve mounted to slide on said post, the said bar having guideways in its front and rear faces, lens and temple carriers mounted to slide in said guideways, means for moving the bar up and down on said post, a pointer moving with said bar, a graduation on said post on which the pointer indicates, a saddle a bar in which the saddle is pivoted, the said bar being adjustable transversely in a bearing at the lower end of the post, means for turning said saddle on its pivot means for adjusting the bar carrying the saddle transversely, a pointer carried by said bar, and a graduation on the bearing in which the bar is mounted, for indicating the distance said bar and saddle are moved as set forth.

9. A measuring device provided with a post having a bearing at its lower end, a bar mounted to slide transversely in said bearing, a saddle having a pivot mounted to turn in said bar, saddle-leaves hinged on said pivot, the said bar being provided at its rear end with a screw-rod, a nut screwing on said screw-rod and having an annular groove, and an arm extending from the bearing for said bar, and having a forked end engaging the groove in the said nut, as set forth.

10. A measuring device provided with a saddle having sets of hinged leaves, a bar having a bearing at one end, a pivot on which the leaves are hinged the pivot being journaled in said bearing, an arm on said pivot for turning the latter and a plate on said bearing and provided with a graduation on which the arm indicates, as set forth.

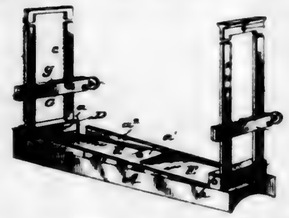
11. A measuring device having a post provided with a bearing at its lower end, a bar mounted to slide transversely in said bearing and having a bearing at one end, a saddle provided with a longitudinally-extending pivot journaled in the latter bearing, and leaves pivoted on the ends of said pivot and of different lengths, as set forth.

12. A measuring device provided with a bar having a longitudinal guideway, temple-carriers mounted to slide in said guideway and provided with racks, each temple-carrier having an angular depending arm, a temple-bar pivoted on said arm and having a spring-pressed earpiece mounted to slide in a bearing on the temple-bar, a bracket mounted to slide on the temple-bar and moving with the earpiece and in which the inner end of the earpiece is mounted to turn, means for indicating the length of the temple, and comprising a graduation formed on the temple-bar and on which the bracket indicates, and a gear-wheel in mesh at opposite sides with the racks on the temple-carriers, as set forth.

13. A measuring device, comprising a post, a bar slidable up and down on the post and provided with guideways, lens and temple carriers slidable in said guideways and provided with racks, pinions meshing at opposite sides with the racks of the lens and temple carriers respectively, and a saddle or crest for the nose supported on said post, as set forth.

14. A measuring device provided with a horizontally-arranged bar having a guideway, lens-carriers mounted to slide in said guideway and having depending arms or brackets supporting the lenses, the lens-carriers being provided with racks, a gear-wheel under the control of the operator and in mesh at opposite sides with said racks for moving said lens-carriers simultaneously toward or from each other, and a pointer on one of the lens-carriers, and indicating on a graduation on the said bar, as set forth.

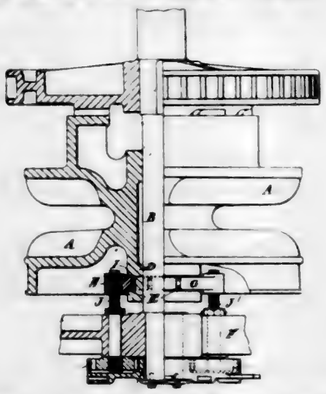
706,890. RANGE-FINDER ATTACHMENT FOR GUNS. ARTHUR P. COLLINS, U. S. Army. Filed Nov. 5, 1901. Serial No. 81,194. (No model.)



Claim.—1. The improved range-finder, comprising a base-piece; a graduated rear frame adapted to be held vertical and serve as an ordinary sight; and the range-finder attachment proper, consisting of a front frame also adapted to be held rigidly vertical parallel to the first-named one, and having a sight-bar which is adjustable vertically thereon, so that it may be brought into line with a distant object and a selected and fixed point on the elevating-sight; both of said frames being graduated correspondingly; substantially as shown and described.

2. The improved range-finder comprising a base-piece; the rear elevating-sight frame, having a sight-guide at the top; the front range-finder attachment proper, consisting of a pivoted frame which is provided with graduations corresponding to those of the rear frame and having rack-teeth which are arranged transversely, the transverse sight-bar adapted to slide on said front frame, and a rotatable shaft having pinions that engage the rack-teeth on the range-finder frame, for adjusting said sight-bar higher or lower, as shown and described.

706,891. CLUTCH. WILLIAM D. COOKSON, Gateshead, England, assignor to Clarke Chapman & Company, Limited, Gateshead, England. Filed July 2, 1901. Serial No. 66,900. (No model.)

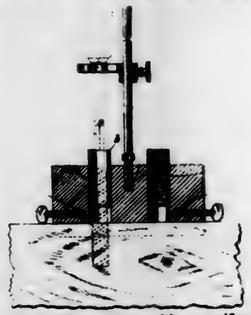


Claim.—1. A clutch comprising in combination a part clutch connected to a shaft so as to rotate therewith, a second part clutch mounted upon said shaft and adapted to be moved along it into or out of engagement with said other part, a groove in said movable part, a ring or strap located in said groove and surrounding said longitudinally-movable part, leaving same free to rotate independently but which ring or strap is adapted when itself moved lengthwise of the shaft to move said part along with it, screw-threaded openings or nuts in said ring or strap, screw-spindles that extend through said openings or nuts, bearings wherein said spindles are mounted and can rotate and whereby they are held longitudinally, spur-wheels on said spindles and in gear with said wheels a central spur-wheel adapted through said spur-wheels, spindles and ring or strap to actuate the movable part, substantially as described.

2. A windlass-clutch comprising in combination a part clutch constituting a cable holder or lifter, or a windlass, and which part is mounted upon a shaft and is adapted to be moved along it into or out of engagement with a second part clutch connected to said shaft so as always to rotate with it, a groove in said movable part, a ring or strap located in said

groove and surrounding said longitudinally-movable part, leaving same free to rotate independently but which ring or strap is adapted when itself moved lengthwise of the shaft to move said part along with it, screw-threaded openings or nuts in said ring or strap, screw-spindles that extend through said openings or nuts, bearings wherein said spindles are mounted and can rotate and whereby they are held longitudinally, spur-wheels on said spindles and in gear with said wheels a central spur-wheel loose on said shaft and formed as a hand-wheel and adapted to operate through said spur-wheels, spindles and ring the movable part, substantially as described.

706,892. HAND DOWELING-GAGE. JOSEPH COLLINS, New York, N. Y. Filed Jan. 23, 1902. Serial No. 91,579. (No model.)



Claim.—1. A doweling-gage, comprising an orificed body portion, a pin or rod transversely adjustable therein, means for rigidly holding the pin or rod, a gage-plate fastened rigidly to one end of the pin or rod, a second gage-plate on the other end of the pin or rod, and nuts working on threaded portions of the pin or rod and lying at opposite sides of the second-named plate, adjustably to hold it.

2. A doweling-gage, comprising an orificed body portion, a rod carried transversely thereby, a gage-plate mounted on one end of the rod, a second gage-plate mounted on the other end of the rod and movable thereon longitudinally thereof, means for adjustably holding the second gage-plate in place, and means for adjustably holding the rod on the body portion.

3. A doweling-gage, comprising a body portion having a hole therein for the boring-tool, said body serving as the gage proper, a transverse rod carried adjustably thereby, and gage-plates carried by the rod, one of said gage-plates being adjustable on the rod in direction longitudinally thereof.

4. A doweling-gage, comprising a body portion forming the gage proper, means for holding the same in place, a standard mounted on the body, and a depth-gage arm adjustably carried on the standard and having a hook-like portion adapted to embrace the bit, for the purpose specified.

5. A doweling-gage, comprising a body portion having a hole therein for the boring-tool, said body forming a gage proper, a rod adjustably mounted therein transversely thereto, means for adjustably holding the rod, and gage-plates carried on the rod and relatively adjustable thereon longitudinally of the rod.

6. A doweling-gage, comprising a body portion serving as the gage proper, a transverse rod movably mounted therein, gage-plates carried on the rod, one of said gage-plates being adjustable thereon, for the purpose specified, a threaded rod or screw working in the body portion and serving adjustably to hold the said transverse rod, and a depth-gage arm adjustably carried on the said rod or screw.

706,893. COUPLING FOR CABLES, ROPES, &c. THADDEUS DARLING, Marietta, Ohio. Filed Jan. 22, 1902. Serial No. 90,773. (No model.)

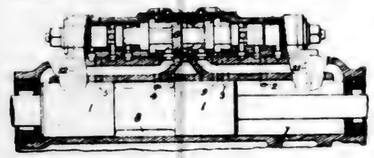
Claim.—1. A coupler of the class described comprising separable members provided on their opposing faces with longitudinal channels, transverse grooves, and cavities of larger cross-sectional area than the channels and intersecting the same.

2. A coupler of the class described comprising separable members provided on their opposing faces with longitudinal registering channels, cavities of larger cross-sectional area than said channels and in communication therewith, said cavities in the members being disposed in matching relation, and grooves intersecting with the channels independently of the cavities.

3. A coupler of the class described comprising a member provided with a shoulder having a cavity which opens through one face of the member, another member having a cavity arranged to coincide with the cavity of the first-named member, channels in said members and in communication with the cavities therein; and means for clamping said members together.

4. A coupler of the class described, comprising a base member having an eye and a shoulder, the latter provided with a recess, a longitudinal channel in said member and having communication with said recess, a companion member provided with a channel and with a recess arranged to coincide respectively with the channel and recess in the base member, and means for laterally clamping the two members together.

706,894. PERCUSSIVE ROCK-DRILL. ZACHARIAS W. DAW, London, England. Filed Jan. 27, 1902. Serial No. 91,517. (No model.)



Claim.—1. The combination with the motor-cylinder of a main valve for regulating the supply and exhaust to and from such cylinder and working in a valve-cylinder, a motor-piston in said motor-cylinder controlling by its movements the ports which govern the operation of the main valve, and a shut-off valve also controlled by said motor-piston for cutting off or practically cutting off the supply to the motor-cylinder, so as to allow the motive fluid to act expansively therein, all substantially as specified.

2. The combination with the motor-cylinder of a main valve for regulating the supply and exhaust to and from such cylinder and working in a valve-cylinder, a motor-piston in said motor-cylinder controlling by its movements the ports which govern the operation of the main valve, and a shut-off valve also controlled by said motor-piston for each end of the motor-cylinder arranged one to cut off or practically cut off the supply alternately to the opposite ends of the motor-cylinder, substantially as and for the purpose specified.

3. The combination with the motor-cylinder of a main valve for regulating the supply and exhaust to and from such cylinder and working in a valve-cylinder, a motor-piston in said motor-cylinder controlling by its movements the ports which govern the operation of the main valve, and a shut-off valve for cutting off or practically cutting off the supply to the motor-cylinder, such shut-off valve being actuated by pistons working in cylinders respectively connected by passages leading one to each end of the motor-cylinder and controlled by the reciprocation of the motor-piston, substantially as specified.

4. The combination with the motor-cylinder of a main valve for regulating the supply and exhaust to and from such cylinder and working in a valve-cylinder, a motor-piston in said motor-cylinder controlling by its movements the ports which govern the operation of the main valve, and a shut-off valve for each end of the motor-cylinder, each of said valves being actuated by a piston working in a cylinder connected respectively by a passage leading one to each end of the motor-cylinder and controlled by the reciprocation of the motor-piston, substantially as specified.

5. The combination with the motor-cylinder of a valve for regulating the supply and exhaust to and from such cylinder and working in a valve-cylinder, and a shut-off valve for cutting off or practically cutting off the supply to the motor-cylinder, such shut-off valve being actuated by pistons working in cylinders respectively connected by passages leading one to each end of the motor-cylinder and controlled by the reciprocation of the motor-piston, said valve being formed with an opening or openings which permit the motive fluid to pass to its under side, substantially as specified.

6. The combination with the motor-cylinder of a valve for regulating the supply and exhaust to and from such cylinder and working in a valve-cylinder, and a shut-off valve for each end of the motor-cylinder, each of said valves being actuated by a piston working in a cylinder connected respectively by a passage leading one to each end of the motor-cylinder and controlled by the reciprocation of the motor-piston, said valve being formed with an opening or openings which permit the motive fluid to pass to its under side so as to open same, substantially as specified.

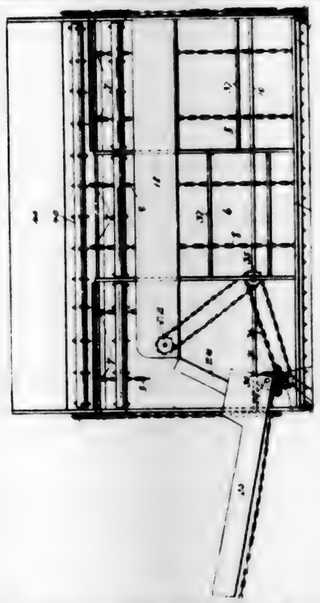
7. The combination with the motor-cylinder of a valve for regulating the supply and exhaust to and from such cylinder and working in a valve-cylinder, and a shut-off valve for each end of the motor-cylinder, each of said valves being actuated by a piston working in a cylinder connected respectively by a passage leading one to each end of the motor-cylinder and controlled by the reciprocation of the motor-piston, the space in front of the valve-piston being connected by a passage to the main exhaust, substantially as specified.

8. The combination with the motor-cylinder of a valve for regulating the supply and exhaust to and from such cylinder and working in a valve-cylinder, and a shut-off valve for cutting off or practically cutting off the supply to the motor-cylinder, such shut-off valve being actuated by pistons working in cylinders each connected by a passage to the motor-cylinder in such a position that a groove formed in the motor-piston will in its reciprocation alternately place one of the piston-cylinders open to exhaust, while the piston in the other cylinder is open to the pressure of the motive fluid which has leaked through small openings formed in such piston to the rear thereof, and the valve is consequently reversed, substantially as specified.

9. The combination with the motor-cylinder of a valve for regulating the supply and exhaust to and from such cylinder and working in a valve-cylinder, and a shut-off valve for cutting off or practically cutting off the supply to the motor-cylinder, such shut-off valve being actuated by pistons working in cylinders respectively connected by passages leading one to each end of the motor-cylinder and controlled by the reciprocation of the motor-piston, and adjustment means for limiting the extent of throw of the shut-off valve, substantially as specified.

10. The combination with the motor-cylinder of a valve for regulating the supply and exhaust to and from such cylinder and working in a valve-cylinder, and a shut-off valve for each end of the motor-cylinder, each of said valves being actuated by a piston working in a cylinder connected respectively by a passage leading one to each end of the motor-cylinder and controlled by the reciprocation of the motor-piston, and of a screw or other adjustable device for limiting the extent of throw of the shut-off valve, substantially as specified.

706,895. ENDLESS-BELT CONVEYER. PETER M. DE JONG, Horton county, Kans. Filed Aug. 1, 1901. Serial No. 70,546. (No model.)



Claim.—1. In a conveyer for feeding corn to a sheller, an endless apron, a studded roller journaled above the point of delivery of said apron, means for rotating said roller and operating said apron, and a trough below the delivery-point of said apron and arranged to carry the corn in a direction at right angles to the direction of the apron, substantially as shown and described.

2. In a conveyer, an upwardly-traveling endless apron, a studded roller under the point of delivery to prevent ears of corn following the returning portion of said endless apron, means to rotate said roller and actuate said apron, and a trough below the delivery-point of said apron and arranged to carry the corn in a direction at right angles to the direction of the apron, substantially as shown and described.

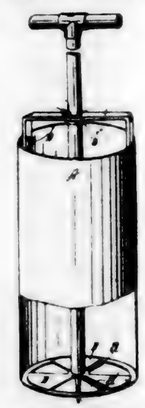
3. In a conveyer, an inclined endless apron, a trough below the point of delivery thereof, an endless apron in said trough, a slide at the delivery end of said trough, a frame arranged below said slide containing an endless apron, said frame being pivoted to swing in a horizontal plane, and means to simultaneously actuate said aprons, substantially as shown and described.

4. In an endless conveyer, endless aprons arranged to travel upward over an inclined plane, a suitably-supported apron arranged below said inclined apron running in a direction at right angles to said apron and adapted to deliver into a trough pivoted to swing on a shaft in a horizontal plane, a horizontal wheel journaled on the shaft on which is pivoted said trough, a beveled gear on the top and bottom edge of said horizontal wheel, a beveled gear meshing with the beveled gear on top of said horizontal wheel to drive an endless apron in said trough, and a beveled gear suitably mounted, meshing with the beveled gear on the bottom edge of said horizontal wheel, and connected with the source of power, substantially as shown and described.

5. In a conveyer for feeding corn to a sheller, studded rollers, an endless apron, slats on said apron, a trough below the delivery-point from said apron, an endless apron in said trough, a swinging trough to receive the ears of corn from the first-mentioned trough, an endless apron in said swinging trough, and means for actuating said studded rollers and endless apron, substantially as shown and described.

6. In a conveyer for feeding corn to a sheller, a frame having a perpendicular back portion and a slanting front, a shaft journaled at the front of the base, a shaft journaled on said perpendicular back portion, sprocket-wheels on said shafts, an endless apron supported by said sprocket-wheels, a studded roller journaled to said perpendicular back portion below said endless apron, and means for operating said studded roller and endless apron, substantially as shown and described.

706,896. DREDGE AND WELL-BORER. CHARLES EHRENFELD, Pasadena, Cal. Filed May 2, 1898. Serial No. 679,557. (No model.)



Claim.—1. A dredge comprising a hollow cylindrical body provided with a bottom having an opening; a yoke extending over the top of the cylinder and provided with upwardly-projecting lugs; a shaft slidingly journaled in the yoke and in the bottom of the cylinder and provided at its lower end above the bottom of the cylinder with a blade to form a gate to close the opening; a lug extending from the side of the shaft above the yoke to engage with the lugs of the yoke to cause the cylinder to rotate with the shaft when the gate is against the bottom of the cylinder; means for temporarily holding the shaft with its lug in position to engage the lugs of the yoke; a screw above the gate and fixed to the shaft; and means for locking the screw against rotation when the shaft is being slid upward.

2. A dredge comprising a hollow cylindrical body provided in its bottom with an opening; a yoke having elongated side arms secured to the top of the casing; a shaft journaled in the yoke and in the bottom of the dredge and having a screw secured thereto, the edges of the screw being provided with notches to engage with the side arms and prevent rotation of the screw, stop-arms on the yoke; a pin on the shaft to en-

gage with the stop-arms; and a collar on the shaft between the top of the yoke and the screw.

706,397. RAKE. ADAM S. ELLIOTT, Mechanicsville, Iowa. Filed Mar. 4, 1902. Serial No. 96,583. (No model.)

Claim.—1. In an apparatus of the class described, a rake-head consisting of longitudinal bars, a series of teeth, and a corresponding series of clamps, each clamp consisting of complementary members having interlocking connection one with the other and adapted to be secured firmly to the bars of the rake-head.

2. In an apparatus of the class described, a tooth-clamp comprising complemental channeled members provided in their opposing faces with projecting shoulders, said shoulders of the members being assembled into interlocking engagement, whereby the shoulders limit endwise displacement of the members relative to each other.

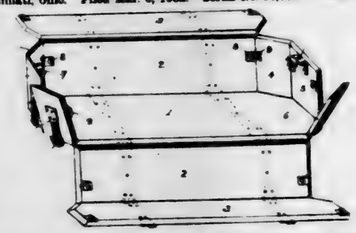
3. In an apparatus of the class described, a rake-head, consisting of longitudinal bars, a series of clamps interposed between said bars and each consisting of members which have interlocking engagement with each other and with the individual bars of said rake-head, and a series of teeth having individual engagement with the members of the clamps.

4. In an apparatus of the class described, a tooth-clamp, consisting of complementary members provided with channels, and with recesses and shoulders on their opposing faces, said shoulders of one member arranged to enter the recesses of the other member, and the shoulders of the two members having engagement one with the other.

5. In an apparatus of the class described, a tooth-clamp, consisting of members each cast in a single piece of metal and having their active faces provided with longitudinal ribs and with tooth-receiving channels, the respective ribs being provided on their edges with the recesses and the shoulders on each member, said members being assembled in reversed positions, and the shoulders of one member interlocking with the shoulders of the other member.

6. In an apparatus of the class described, a tooth-clamp consisting of members each cast in a single piece of metal and provided on its outer side with a transverse rib and with a longitudinal rib, each member being also provided on its inner face with longitudinal flanges which are enlarged and formed with the facing abutments or shoulders.

706,398. ADJUSTABLE COUCH-CASKET. JOSEPH KENNY, Cincinnati, Ohio. Filed Mar. 6, 1902. Serial No. 96,957. (No model.)



Claim.—1. The couch-casket having independent angularly-movable sides, top and end boards, said sides and ends being attached to the bottom by hinges having heads with a circumferential series of slots therein and a coöperating bolt to fit in any one of said slots whereby the parts may be adjusted and fixed in any desired angular position, to form couches of varying shapes, as set forth.

2. An adjustable couch-casket having movable top, sides and end pieces, each joined with a hinge provided with means for setting and locking the same at any desired angle, and provided also, with removable filling plates or boards to close the spaces between the said ends and sides when the same are set at an angle with the normal vertical.

3. A couch-casket having hinged sides and end pieces adjustable in position angularly, and removable filling plates or boards to close the spaces between said sides and end pieces when the same are spread apart.

4. A couch-casket having hinged sides and end pieces each provided with slots in its edges, and sets of filling plates or boards designed to rest in said slots and close the spaces between the sides and end pieces when the same are spread apart at any angle.

5. An adjustable casket having hinged sides and top and surrounded with a continuous series of straps hinged at the corners and having means for fastening the loose ends across the top of the casket.

6. A casket having hinged sides, top and end pieces, adjustable in angular position, some of the end pieces being provided with perforated brackets and the top having fixed studs arranged to fit in the said perforations of the brackets when the casket is closed in normal position.

706,399. TOY CANNON. ARCHIE G. PIPER, Quincy, Ill. Filed Oct. 23, 1901. Serial No. 79,094. (No model.)

Claim.—1. The combination with the slotted and shoulder-bored toy gun, of the mainspring and headed plunger, the pivoted angular spring-catch and reciprocating trigger, substantially as specified.

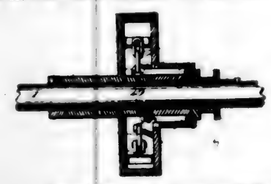
2. The combination with the slotted and shoulder-bored toy gun, of the angular slotted catch, the reciprocating trigger, movably connected therewith, the spring connected with said trigger and bearing against the catch, the mainspring and the headed plunger, substantially as specified.

3. The combination with the slotted shoulder-bored and screw-breeched toy gun, of the mainspring, and headed plunger, the pivoted catch, and the reciprocating trigger, connected to said catch, substantially as specified.

4. The combination with the shoulder-bored toy gun, its screw-breech piece, the mainspring, and headed plunger, of the catch and trigger, the bed and pivoted carriage, substantially as specified.

5. A toy gun, comprising a bed, a pintle-carriage, a slotted shoulder-bored gun and screw-breech, trunnion-pins, a mainspring and headed plunger, a pivoted spring-catch, and a reciprocating trigger connected thereto, substantially as specified.

706,400. FRICTION-CLUTCH. CHARLES A. FISHER, Thorold, Canada, assignor of one-tenth to Curt C. Andrews, North Tonawanda, N. Y. Filed Oct. 15, 1901. Serial No. 78,720. (No model.)

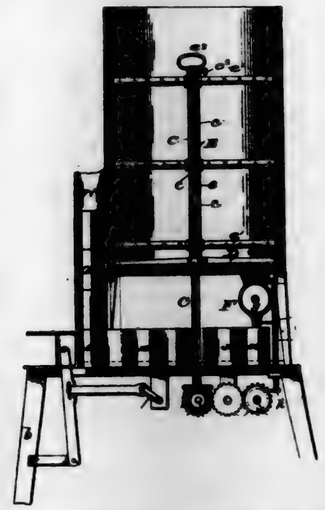


Claim.—1. A friction-clutch comprising a revolvable pulley, a fixed disk, arms pivotally secured to the disk, levers fulcrumed upon the disk and having friction-shoes, connections between the arms and levers, and laterally-movable means for operating the arms and levers.

2. A friction-clutch comprising a loosely-mounted pulley, a fixed disk having a slotted sleeve extension, arms pivotally secured within said extension, oppositely-disposed levers fulcrumed upon said disk, connections between said arms and levers, a sliding sleeve for operating said arms and friction-shoes secured to said levers.

3. A friction-clutch comprising a loosely-mounted pulley; a fixed disk having a sleeve extension; arms pivotally secured within the said extension; oppositely-disposed curved levers fulcrumed upon said disk and connected to the ends of said arms; retracting-springs for said levers; friction-shoes adjustably supported upon the inner face of said disk; and a sliding sleeve for forcing said arms toward each other.

706,401. COMBINED CORN COOKING AND CANNING MACHINE. LEONARD S. FLECKENSTEIN, Easton, Md. Filed Dec. 4, 1901. Serial No. 84,664. (No model.)

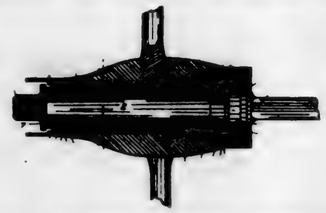


Claim.—1. In a corn cooking and canning machine, the combination with the vertical corn-receiver, and the hollow, apertured, vertical shaft, supported in the lower portion of the machine and projecting upward and terminating freely in said receiver and means for rotating said shaft, of the agitator formed of a central apertured tube, and lateral hollow arms having apertures for discharging steam, the said agitator being supported on the shaft and adapted to be drawn upward and removed from both the shaft and receiver, as required for cleaning it, as shown and described.

2. In a machine of the character described, the combination, with a corn-receiver, of a casting secured to the under side of the same and having a transverse bore provided with a central partition, two connected pistons arranged to reciprocate in the two chambers formed on opposite sides of said partition, two inlet and two discharge passages arranged vertically opposite each other in the upper and lower sides, respectively, of the casting, the two discharge-passages opening adjacent to the partition and diverging therefrom downward, and two slidable valves provided with slots arranged as described, and means for operating said pistons and valves, whereby the pistons are continuously reciprocated, and the valves are intermittently reciprocated, as required for closing and opening coincident inlet and discharge openings, simultaneously, substantially as shown and described.

3. In a machine of the character described, the combination, with a corn-receiver, having two discharge passages, two chambers communicating with each passage and having discharge-passages as specified, a central partition dividing the two chambers from each other, two pistons and a rod connecting the same and passing through said partition, the pistons being separated a distance sufficient to admit a corn charge between each of them and the partition; means for imparting continuous reciprocation to the pistons; and two valves slotted as described, and arranged in guideways above and below the pistons; a rock-shaft connected with said valves, and a rotatable cam having an abrupt offset with which an arm of the said rock-shaft engages, substantially as shown and described, whereby the valves are moved suddenly and simultaneously immediately preceding a return movement of the pistons, thereby alternately cutting off an inlet and closing a discharge passage of the respective chambers, as specified.

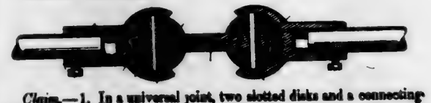
706,402. AXLE-BOX FOR CARRIAGES OR WAGONS. CLARENCE M. FLORET, Scranton, Pa., assignor of one-fourth to John H. Brooks, Scranton, Pa. Filed Nov. 23, 1900. Serial No. 37,092. (No model.)



Claim.—1. In a vehicle-axle box, the combination of an inner sheath adapted to revolve on the vehicle-spindle, an outer shell concentric therewith, and mounted thereon, inner end and outer end antifriction-bearings between cups incasing the outer end bearings thereof, said cups being of a diameter less than the general distance between the outside walls of the shell aforesaid, whereby the assembled parts are insertible endwise through the hub of a wheel, filling the same, substantially as specified.

2. In a vehicle-axle box, the combination of an inner sheath adapted to revolve on the vehicle-spindle, and an outer shell concentric therewith and mounted thereon, inner end and outer end antifriction-bearings, cups incasing the said outer end bearings thereof, the diameters of said cups being less than the minimum diameter of said outer shell, the said inner and outer shell aforesaid having a space between them adapted to be filled with lubricant, and ports leading to the inner end and outer end bearings, substantially as and for the purpose specified.

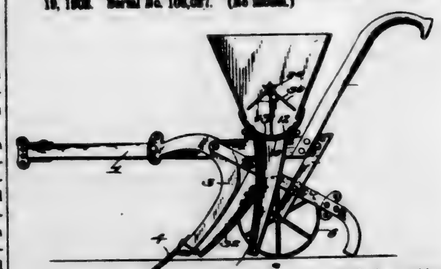
706,408. UNIVERSAL JOINT FOR SHAFTING. JOSEPH L. FOLLETT, New York, N. Y., assignor to the Follett Machine Company, New York, N. Y. Filed Jan. 11, 1901. Renewed July 9, 1902. Serial No. 114,954. (No model.)



Claim.—1. In a universal joint, two slotted disks and a connecting-link pinned or pivotally jointed to the same, in combination with yokes, provided each with a bearing-groove to receive one of the disks, said groove being concentric with its disk, and having a curved portion of not more than one hundred and eighty degrees in extent, substantially as and for the purposes hereinbefore set forth.

2. The yokes provided each with a socketed hub and with a bearing-groove having a curved portion of not more than one hundred and eighty degrees in extent the walls of which are integral with the body of the yoke, in combination with slotted disks entered and fitting in said grooves, and a connecting-link jointed to said disks, substantially as and for the purposes hereinbefore set forth.

706,404. COMBINED SEED-PLANTER AND FERTILIZER-DISTRIBUTER. ABRAHAM G. W. FOSTER, Sr., Powellville, Ga. Filed May 19, 1902. Serial No. 108,027. (No model.)

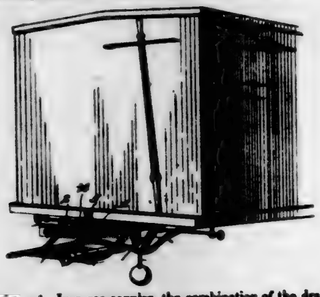


Claim.—1. In a machine of the character described, the combination of the plow-frame, the combined seed and fertilizer hopper having a concave bottom, the ground-wheel journaled in downwardly-projecting arms adjustably connected to the plow-beam, brace-bars connected to the plow-beam and to said adjustable arms, covering-blades secured to the outer ends of the brace-bars, a discharge-tube connected with the seed-compartment and a discharge-tube connected with the fertilizer-compart-

ment, a feed-opening in the bottom of the fertilizer-compartment, a sliding valve for regulating said feed-opening, means for operating said sliding valve from the outside of the hopper, an adjustable cotton-seed feed-plate and an adjustable grain-seed feed-plate adapted to be interchangeable with each other and adapted to cover a feed-opening in the bottom of the seed-compartment, an agitator-shaft journaled in the sides of the hopper, adjustable agitator-arms carried by said agitator-shaft, a crank-arm fixed to one end of said agitator-shaft, and a crank-arm fixed to the shaft of the ground-wheel, a pitman connecting the said crank-arms whereby motion is imparted from said ground-wheel to said agitator-shaft, substantially as set forth.

2. In a machine of the character described, the combination of the plow-frame, the combined seed and fertilizer hopper having a concave bottom, the ground-wheel journaled in downwardly-projecting arms adjustably connected to the plow-beam, brace-bars connected to the plow-beam and to said adjustable arms, covering-blades adjustably secured to the outer ends of the brace-bars, a discharge-tube connected with the seed-compartment and a discharge-tube connected with the fertilizer-compartment, a feed-opening in the bottom of the fertilizer-compartment, a sliding valve for regulating said feed-opening, a lever pivoted to the side of said hopper and connected at its lower end to said sliding valve to operate the same, an adjustable cotton-seed feed-plate and an adjustable grain-seed feed-plate adapted to be interchangeable with each other and adapted to cover a feed-opening in the bottom of the seed-compartment, an agitator-shaft journaled in the sides of the hopper, adjustable agitator-arms carried by said agitator-shaft, a crank-arm fixed to one end of said agitator-shaft, and a crank-arm fixed to the shaft of the ground-wheel, and an adjustable pitman connecting the said crank-arms whereby variable movements may be imparted to said agitator-shaft, substantially as set forth.

706,405. CAR-COUPLING. EDWARD FOSTER, Cleveland, N. Y. Filed July 14, 1900. Serial No. 23,672. (No model.)



Claim.—1. In a car-coupler, the combination of the draw-bar pivotally secured at one end of the car, a coupling head or member on the end, and a weighted bar secured to the other end passing through a sleeve pivotally mounted in brackets on the under side of the car whereby to correct any lateral deviation of the draw-bar from a line with the car.

2. In a car-coupler, the combination of the draw-bar pivotally secured at one end of the car, a coupling head or member on the front end, a collar slidably mounted on its rear end and a weighted rod secured to the other end passing through a sleeve pivotally mounted in brackets on the under side of the car whereby to correct any lateral deviation of the draw-bar from a line with the car.

3. In a car-coupler, the combination of the draw-bar pivotally secured at one end of the car, a barbed coupling head or member on the forward end, and a weighted rod secured to the other end passing through a sleeve pivotally mounted in brackets on the under side of the car, whereby to correct any lateral deviation of the draw-bar from a line with the car.

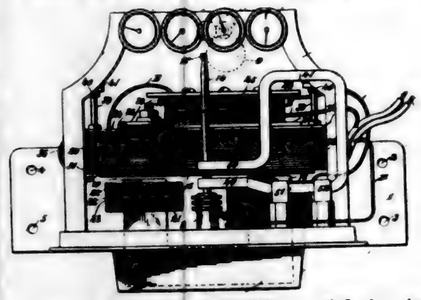
4. In a car-coupler the combination of the draw-bar, pivotally secured at one end of the car, a barbed coupling head or member in the forward end, a loose collar on its reduced cylindrical rear end, and a weighted rod secured to the other end passing through a sleeve pivotally mounted in brackets in the under side of the car, whereby to correct any lateral deviation from a line lengthwise of the car, substantially as described.

5. In a car-coupler, the combination, with the bumper, of a bar pivotally secured thereto to swing in a horizontal plane the forward end of which is provided with an inclined hook, and the rear end is cylindrical in form, a thimble upon said cylinder, a weighted rod secured thereto, and a fulcrum for said bar in alinement with the coupling-bar and the thimble, substantially as described.

6. In a car-coupler, the combination, with the bumper, of a bar pivotally secured thereto to swing in a horizontal plane, the forward end of which is provided with an inclined hook and the rear end is cylindrical, a thimble upon the cylindrical portion, braces secured to the under side of the car, a sleeve pivotally secured between said braces and a weighted rod secured to the thimble and extending down through said sleeve, substantially as described.

7. In a car-coupling a bar provided at one end with two upcast and internally-projecting hooks having beveled faces a reduced portion at its other end a vertical opening adjacent to the reduced portion and an intermediate inclined portion projecting from the same side of the car as the hooks, as set forth.

706,406. CURRENT-METER. GEORGE L. GOWLLAND, Peterboro, Canada. Filed Mar. 22, 1902. Serial No. 99,472. (No model.)



Claim.—1. In a current-meter in which a magnetic flux is employed for giving movement to the indicating mechanism, the combination of a revolvable member, a magnet and a flux-plate connected with said magnet and extending therefrom to a point adjacent to said revolvable member.

2. A current-meter comprising indicators, a revolvable disk of conducting material for actuating the same, electric mains, a solenoid-coil provided with a core of non-magnetic conducting material, a conducting-plate of non-magnetic material mounted upon said core, a flux-plate connected with said conducting-plate and disposed adjacent to said disk for the purpose of inducing eddy-currents therein, a magnet connected with said mains, and a laminated flux-plate connected with said magnet and disposed adjacent to said disk for inducing eddy-currents therein, said flux-plates being mounted adjacent to each other and upon opposite sides of said disk.

3. A current-meter, comprising indicating mechanism, a revolvable member for actuating said mechanism and driven by eddy-currents, electric mains and a magnet energized thereby, the said magnet being provided with a flux-plate of a non-magnetic material disposed adjacent to said revolvable member for generating eddy-currents.

4. A current-meter, comprising indicating mechanism, a revolvable member for actuating said indicating mechanism and driven by eddy-current, electric mains, a magnet energized thereby, and a flux-plate of non-magnetic material connected with said magnet and extending therefrom to a point adjacent to said revolvable member.

5. A current-meter comprising indicators, a revolvable disk of conducting material for actuating the same, a magnet provided with a composite core consisting of alternately-disposed members of magnetic material and non-magnetic material, and a flux-plate built up of a laminæ of conducting but non-magnetic material, said laminæ being insulated from each other, and said flux-plate being mounted upon said magnet and disposed adjacent to said disk.

6. A current-meter comprising indicators, a revolvable disk of conducting material for actuating the same, a laminated flux-plate disposed adjacent to said disk, another flux-plate mounted adjacent to said disk and also adjacent to said laminated flux-plate, and magnetic members for exciting both of said flux-plates, said magnetic members being energized by the current to be measured.

7. A current-meter comprising indicators, a revolvable disk of conducting material for actuating the same, a magnetic member, means connected with the main circuit for exciting said magnetic member, and a flux-plate built up of conducting laminæ insulated from each other and fitted upon said magnetic member, said laminæ being disposed parallel with said disk and adjacent thereto.

8. A current-meter comprising indicators, a revolvable member of non-magnetic but conducting material for actuating the same, a magnetic member consisting of a solenoid-coil provided with a longitudinal core of conducting but non-magnetic material, a flux-plate of similar material connected with said core and extending therefrom to a point adjacent to said disk, and a solenoid-core provided with a plate for generating eddy-currents, said plate being disposed adjacent to said disk.

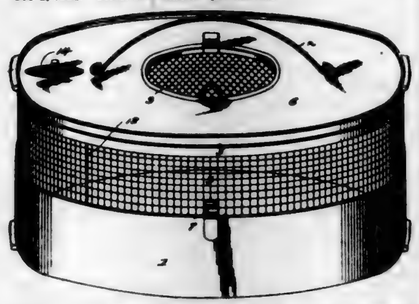
9. A current-meter comprising indicators, a revolvable member of non-magnetic but conducting material for actuating the same, a magnetic member consisting of a solenoid-coil provided with a longitudinal core of conducting but non-magnetic material, a flux-plate of similar material connected with said core and extending therefrom to a point adjacent to said disk, a solenoid-coil provided with a plate for generating eddy-currents, said plate being disposed adjacent to said disk, and means controllable at will for adjusting said flux-plate relatively to said disk.

10. A current-meter comprising indicators, a revolvable disk of non-magnetic but conducting material for actuating the same, a two-pole magnet having one of its poles provided with a coil and the other not so provided, and a longitudinal flux-plate of non-magnetic but conducting material mounted upon said last-mentioned pole, said flux-plate being disposed parallel to said disk, and means for energizing said magnetic member.

11. A current-meter comprising indicators, a revolvable disk of non-magnetic but conducting material for actuating the same, a two-pole magnet consisting of two iron members and a copper member sandwiched between the same, all of said members being provided with a common winding, said magnet having both of its poles disposed adjacent to said disk, and a laminated flux-plate detachably secured upon one of said poles and disposed adjacent to said disk.

12. A current-meter comprising indicators, a revolvable disk of non-magnetic but conducting material for actuating the same, a magnet, means for exciting the same from the current to be measured, a flux-plate mounted upon said magnet and built up of laminæ insulated from each other, said laminæ being disposed parallel to said disk, a solenoid-coil provided with a core of non-magnetic but conducting material, a flux-plate connected with said core and extending therefrom to a point adjacent to said disk, said flux-plates being disposed opposite to each other and also adjacent to opposite positions of said disk, and a solenoid provided with a flux-plate mounted adjacent to said disk and adjustable relatively thereto.

706,407. BAIT-BUCKET. JAMES B. HALL, Cleveland, Ohio. Filed Oct. 2, 1901. Serial No. 77,286. (No model.)



Claim.—1. A bait-basket made in telescopic sections, frictionally held in position, one of said sections being reticulated, as set forth.

2. A bait-basket made in telescopic sections frictionally held in position, one of said sections being reticulated, and stays secured to one section and engaging the other section for giving additional support to the movable section, as set forth.

3. A bait-basket comprising a main section, and a movable section of reticulated material having a bottom-holding ring snugly fitting within the main section, as and for the purpose specified.

4. A bait-basket formed in telescopic sections with the one section fitting tightly within the other to be held frictionally in its adjusted positions, the upper edge of the movable section and the lower edge of the outer section being provided with outwardly-extending lugs as and for the purpose specified.

5. A bait-basket formed of telescopic sections one of which is reticulated, the inner and movable section being provided with an independent, elastic, inflatable air-chamber serving as a float and held in position by the distention of the walls thereof, as set forth.

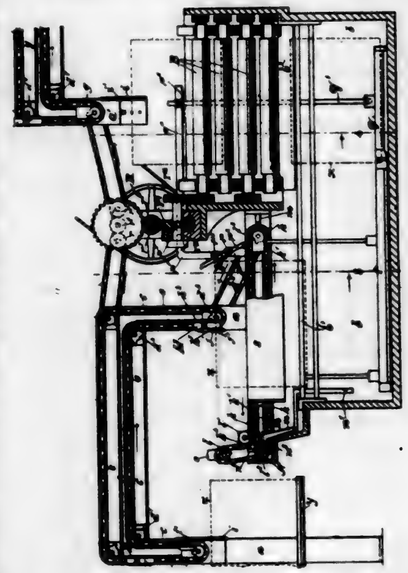
6. A bait-basket in telescopic sections provided with a telescopic separate bait-compartment, as set forth.

7. A bait-basket in telescopic sections, and provided with tubes for the admission of water to the bottom section, as and for the purpose specified.

8. In a bait-basket the combination with a main section, of a section movable therein, and telescopic tubes carried by the movable section, as set forth.

9. A bait-basket composed of a main non-reticulated section, a reticulated section movable therein and frictionally held in position, a partition within the main section at one end, and a partition depending from the movable section and movable within the compartment formed by the partition of the main section, and a removable closure to an opening in the top of the movable section to permit access to said compartment, as set forth.

706,408. APPARATUS FOR COATING METAL PLATES. GEO. B. HAMMOND and THOMAS DENNIS, South, England; said Dennis assignor to said Hammond. Filed Aug. 23, 1901. Serial No. 73,080. (No model.)



Claim.—1. In a machine for coating plates, the combination with a bath-pot and means for conveying plates to and from same, of means movable longitudinally of said bath-pot for pushing the plates therethrough, and means engaging said pushing means for alternately moving the same forward and back again to its initial position.

2. In a machine for coating plates, the combination with a bath-pot, of conveyer-chains and means coöperating with said conveyer-chains for automatically delivering the plates to the bath-pot, moving the same longitudinally therethrough, and delivering the plates to one of said conveyer-chains.

3. In a machine for coating plates, the combination with a bath-pot, of conveyer-chains for conveying the plates to and from said bath-pot, means for pushing said plates longitudinally through said bath-pot, means for elevating said plates from said bath-pot, and means coöperating with said conveyer-chains, engaging and automatically operating said pushing and elevating means.

4. In a machine for coating plates, the combination with a bath-pot; of a rail above said bath pot, a block on said rail, an extension on said block for pushing plates through said bath-pot, and means for propelling said block along said rail, substantially as described.

5. In a machine for coating plates, the combination with a bath-pot; an endless chain arranged to travel above said pot, grippers upon said chain, means for closing said grippers upon a plate, and means for opening said grippers when over said pot to drop said plate in the pot; of a rail above said pot, a block sliding on said rail, an extension on said block for pushing said plate, and means for propelling said block along said rail, substantially as described.

6. In a machine for coating plates, the combination with a bath-pot; and a cradle in said bath-pot; of means for conveying plates to said bath-pot, means for pushing said plates through said bath-pot into said cradle, means for raising said cradle, a set of rolls for lifting the plate from said cradle, and a conveyer for removing the plate from said rolls, substantially as described.

7. In a machine for coating plates, the combination with a bath-pot; a conveyer for placing the plates to be coated in said pot, of a block arranged to slide above said pot, an extension on said block for pushing said plates through said pot, a cradle in said pot for receiving the plates, a lever operated by said sliding block for lifting said cradle, a set

of rolls for lifting the plate from the cradle, and a conveyer for removing the plates from said rolls, substantially as described.

8. In a machine for coating plates, the combination with a bath-pot, a conveyer for placing the plates to be coated in the pot, a block arranged to slide above said pot, an extension on said block for pushing said plates through said pot, a cradle in said pot, a lever p^4 to which said cradle is attached, a weighted lever in the path of said sliding block adapted to act on the lever p^4 to lift said cradle, a set of rolls for lifting said plate from said cradle, and a conveyer for removing said plates from said rolls, substantially as described.

9. In a machine for coating plates, the combination with a bath-pot, a flux-box above said bath-pot, guide-bars, and a cradle in said bath-pot; of means for conveying plates to said bath-pot, means for pushing said plates through said bath-pot into said cradle, means for raising said cradle and means for removing the plate from said cradle, substantially as described.

10. In a machine for coating plates, the combination with a bath-pot, of a rail above said pot, a block arranged to slide on said rail and having an extension extending into said pot, lugs on said block extending above and below the same, a chain running and returning parallel with said rail and having a pin adapted to engage said lugs and move said block forward and backward along said rail, substantially as described.

11. In a machine for coating plates, the combination with a bath-pot, of a rail above said pot, a block arranged to slide on said rail and having an extension extending into said pot, lugs on said block extending above and below the same, a chain running and returning parallel with said rail and having a pin adapted to engage said lugs and move said block forward and backward along said rail, a lever p^4 connected with the said cradle, a lever P arranged in the path of one of the lugs on said sliding block and adapted to actuate the lever p^4 to raise said cradle, substantially as described.

12. In a machine for coating plates the combination with a bath-pot; of conveying means operating adjacent thereto, comprising a movable frame, a gripping-jaw pivoted thereto, provided with an inwardly-projecting lug, and a sliding lock adapted to engage said lug for holding said jaw in its open or closed position; and means located in the path of said movable frame for opening and closing said gripping-jaw.

13. In a machine for coating plates, the combination with a bath-pot; of conveying means operating adjacent thereto, comprising a movable frame, a gripping-jaw pivoted thereto, provided with an inwardly-projecting lug having a beveled end, and a sliding lock provided with a beveled point adapted to alternately engage said lug on its upper and beveled face for holding said gripping-jaw open and closed, respectively; and means located in the path of said movable frame for opening and closing said gripping-jaw.

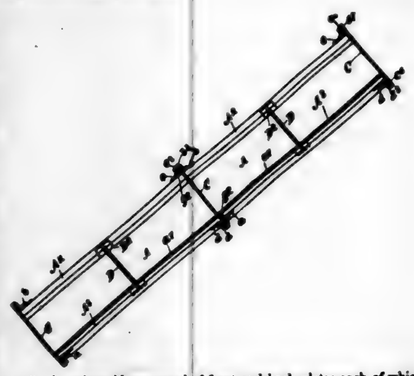
14. In a machine for coating plates, the combination with a bath-pot and conveyer-chains located adjacent thereto; of gripping devices carried by said conveyer-chains comprising a slotted frame, a gripping-jaw pivoted thereto and provided with pins operating in said slots, and a sliding lock for holding said jaw in its open or closed position; and means located adjacent the path of said conveyer-chains adapted to engage said pins for opening and closing said gripping-jaw.

706,409. NUT-LOCK. FRANK HART, Newcastle, Pa., assignor of two-thirds to Frank J. Bolinger, George H. Bolinger, James O. Sutherland, and Joseph Cobery Perkins, Newcastle, Pa. Filed Apr. 30, 1902. Serial No. 105,264. (No model.)

Claim.—The nut-lock herein described consisting of the washer having a body portion provided with an opening for the bolt, having the projecting anchor-lugs at its opposite edges of a length sufficient to space said body portion of the washer away from the abutment in the use of the bolt, whereby to secure the resilience of the washer and to supplement the resilience of the shanks carrying the locking-tongues, and the opposite locking-tongues and their shanks, said shanks projecting from the opposite edges of the body of the washer and the tongues being returned over the said shanks and inclined with respect thereto, as and for the purposes set forth.

706,410. MOLD FOR CEMENT OR CONCRETE CURBS. JOHN T. HARNEY, Garfield, N. J. Filed Sept. 26, 1901. Serial No. 76,444. (No model.)

Claim.—1. A curb-mold composed of separate similar sections each of which is composed of a front and back plate and detachable end plates and a central detachable partition-plate, one end of the front and back plates of each section being provided with two fastening-points arranged at different distances apart, and the other end of the front and back plates of each section being provided with a single fastening-point at different distances from the tops of said plates, and the end plates being each provided at its opposite sides with three fastening-points, the fastening-points at one side being farther apart than those at the opposite sides, substantially as shown and described.



2. A curb-mold composed of front and back plates each of which is provided at its opposite ends with fastening devices differently arranged, and an end plate provided at its opposite sides with fastening devices differently arranged and adapted to be connected with either end of the mold, whereby a plurality of separate molds may be connected, substantially as shown and described.

3. A curb-mold composed of separate sections, each of which is composed of a front plate provided at the top thereof and at the inner edge with a longitudinal groove, each of said plates being also provided at their opposite ends with fastening devices differently arranged, and end plates having fastening devices at their opposite sides which are differently arranged, whereby a plurality of said sections may be connected, substantially as shown and described.

4. A curb-mold composed of separate sections, each of which is composed of a front plate provided at the top thereof and at the inner edge with a longitudinal groove, each of said plates being also provided at their opposite ends with fastening devices differently arranged, and end plates having fastening devices at their opposite sides which are differently arranged whereby one of said sections of the mold may be connected with either end of the other section, and said end plates be secured between said section and at either end thereof, each of said sections being also provided centrally with a removable partition-plate, substantially as shown and described.

5. A curb-mold composed of separate sections, each of which is composed of a front and back plate, the front plate being provided at one end with fastening lugs or projections a^3 and at the opposite end with fastening lugs or projections d^3 and the back plate being provided at one end with a fastening lug or projection c^3 and at the opposite end with fastening lugs or projections b^3 and an end plate provided at one side with fastening lugs or projections c^3 and at the opposite side with fastening lugs or projections c^3, substantially as shown and described.

6. A curb-mold composed of separate sections, each of which is composed of a front and back plate, the front plate being provided at one end with fastening lugs or projections a^3 and the opposite end with fastening lugs or projections d^3 and the back plate being provided at one end with a fastening lug or projection c^3 and at the opposite end with fastening lugs or projections b^3 and an end plate provided at one side with fastening lugs or projections c^3, said front plate being also provided in the top thereof with a longitudinal groove, substantially as shown and described.

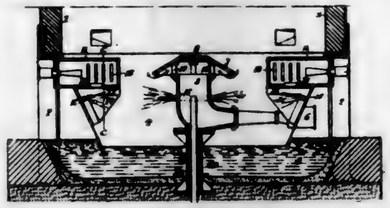
7. A curb-mold composed of separate sections, each of which is composed of a front and back plate, the front plate being provided at one end with fastening lugs or projections a^3, and the opposite end with fastening lugs or projections d^3 and the back plate being provided at one end with a fastening lug or projection c^3, and at the opposite end with fastening lugs or projections b^3, and an end plate provided at one side with fastening lugs or projections c^3, said front plate being also provided in the top thereof with a longitudinal groove, and the separate sections of the mold being provided with central transverse removable partition-plates, substantially as shown and described.

706,411. PROCESS OF EXTRACTING ELLAGIC ACID. ADOLF HEIDEMANN, Eberswalde, Germany. Filed Oct. 26, 1901. Serial No. 80,123. (Specimens.)

Claim.—1. The process herein described of producing ellagic acid from tanning materials containing it, which consists in concentrating an aqueous extract of the crude tanning substances to a specific gravity of 1.2, and then separating the crystalline and insoluble ellagic acid from said extract, substantially as set forth.

2. The process herein described of producing ellagic acid from tanning materials containing it, which consists in concentrating an aqueous extract of the crude tanning substances to a specific gravity of 1.2, separating therefrom the crystalline insoluble ellagic acid, inverting the ellagic-acid compound contained in the extracted husks by boiling them with a suitable acid, filtering off the acid, and separating the ellagic acid set free by the inversion from the residue.

706,412. GAS-PRODUCER. JAMES A. HERRICK, Philadelphia, Pa. Filed Apr. 10, 1902. Serial No. 102,234. (No model.)



Claim.—1. The combination in a gas-producer, of a central blast-pipe for supplying air to the mass of fuel in the producer, with inwardly-projecting twyer-boxes independent of said central blast-pipe and having openings, inwardly beyond the wall or casing of the producer, for supplying air to the fuel between said wall or casing, and the central blast-pipe, substantially as specified.

2. The combination in a gas-producer, of a central blast-pipe having a top grating and a hood for supplying air independently to the central portion or core of the mass of fuel in the producer and to the mass of fuel surrounding said central core, with inwardly-projecting twyer-boxes independent of said central blast-pipe for supplying air to the outer mass of fuel adjacent to the wall or casing of the producer, substantially as specified.

3. The combination in a gas-producer, of an ash-hopper, air-blast pipes for supplying air to the fuel in the producer, and pipes disposed so as to project water laterally into the mass of ashes in the ash-hopper below the air-blast openings, substantially as specified.

4. The combination in a gas-producer, of an ash-hopper, air-blast pipes for supplying air to the fuel in the producer, and inner and outer pipes for supplying water to the ashes in the ash-hopper below the air-blast openings, substantially as specified.

5. The combination in a gas-producer, of a water-cooled ash-hopper, air-blast pipes for supplying air to the fuel in the producer, and pipes disposed so as to project water laterally into the mass of ashes in the ash-hopper between the air-blast openings and the water seal, substantially as specified.

6. The combination in a gas-producer, of a water-cooled ash-hopper, air-blast pipes for supplying air to the fuel in the producer, and inner and outer pipes for supplying water to the ashes in the ash-hopper between the air-blast openings and the water seal, substantially as specified.

7. The combination in a gas-producer, of an ash-hopper having inwardly-projecting twyer-boxes, and brackets secured to the ash-hopper and serving as supports for said twyer-boxes substantially as specified.

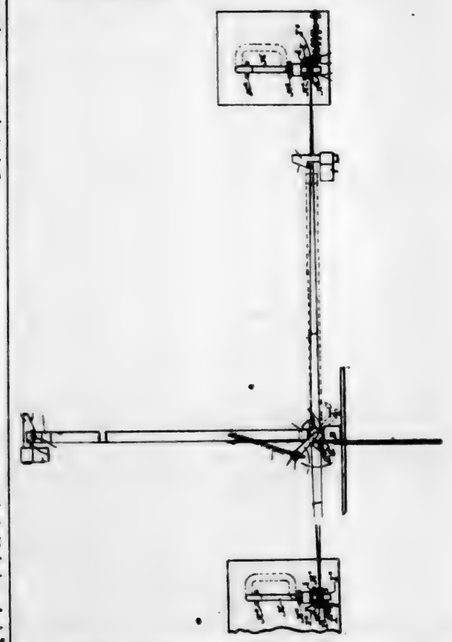
8. The combination in a gas-producer, of the main body or casing, and the ash-hopper with inwardly-projecting twyer-boxes adjustable from and toward the center of the producer, substantially as specified.

9. The combination in a gas-producer, of the main body or casing, and the ash-hopper with a central blast-pipe and inwardly-projecting twyer-boxes adjustable from and toward said central blast-pipe, substantially as specified.

10. The combination in a gas-producer, of the ash-hopper having inwardly-projecting twyer-boxes, and supporting-brackets therefor having projecting portions serving to engage the twyer-boxes and prevent lateral displacement of the same, substantially as specified.

11. The combination in a gas-producer, of the ash-hopper having inwardly-projecting twyer-boxes with central longitudinal slots in the bottom portions thereof, and supporting-brackets for said twyer-boxes having guiding lugs or fingers projecting into said slots, substantially as specified.

706,418. GATE. TERRELL A. HILL, Maryville, Tenn., assignor of one-half to Vernondo B. McClung. Filed Feb. 13, 1902. Serial No. 93,944. (No model.)



Claim.—1. The combination with a gate secured by a vertical hinge to an upright post, of a spring connected to said gate, and means for shifting the direction of the action of said spring from one side of the plane of said gate across said plane prior to the movement of the gate, substantially as described.

2. The combination with a gate and a hinge-post, said gate being secured to said post by a vertical hinge, two stop-posts, a spring applied to said gate, and mechanism for shifting said spring from one side of the plane of said gate to the other prior to the movement of the gate, substantially as described.

3. The combination of a gate and a hinge-post, the gate being secured to the post by a vertical hinge, stop-posts, a spring applied by one end to the gate, and means for shifting the other end of said spring rearward from one side of the plane of the gate to the other, substantially as described.

4. The combination of a gate, a hinge-post and a vertical hinge-shaft joining said gate and said post, the upper end of said shaft being extended and bent laterally, a spring joined to the upper end of said shaft and said gate, means for rotating said hinge-shaft so as to carry said upper end rearward across the plane of the gate, and stop-posts for limiting the movement of the gate, substantially as described.

5. The combination with a horizontally-swinging gate, a stop-post, and latch mechanism, of means for simultaneously drawing the gate toward said stop-post and unlocking the latch mechanism, substantially as described.

6. The combination of a gate, a hinge-post and a vertical hinge-shaft joining said gate and said post, the upper end of said shaft being extended and bent laterally, a spring joined to the upper end of said shaft and said gate, means for rotating said hinge-shaft so as to turn said upper end rearward across the plane of the gate, stop-posts for limiting the movement of the gate, and latch mechanism for securing the gate to said stop-posts, substantially as described.

7. The combination with a horizontally-swinging gate, and a post against which said gate rests when closed, of a spring drawing said gate at the side at which the stop-post is located, a member to which said spring is attached, means for moving said member away from said gate and said stop-post and then across the plane of said gate, whereby greater pulling force is exerted upon said gate in the direction of said stop-post immediately before pulling force is exerted upon said gate in the opposite direction, substantially as described.

8. A horizontally-hinged gate, a stop-post for engaging said gate when closed, a spring attached by one end to said gate and by the other to a tension member, such a tension member mounted upon a vertical axis, and mechanism for revolving said member partially around said axis from a point at one side of the plane of said gate rearward across the plane of said gate, substantially as described.

9. The combination of a horizontally-swinging gate, a stop-post, latch mechanism, a spring attached by one end to said gate and by the other end to a shiftable member, and a latch-cord secured by one end to said latch mechanism and by its other end to said spring at a point intermediate the ends of said spring, substantially as described.

10. The combination of a hinge-post, the gate, a hinge-shaft, C, extended laterally at its upper end, a swivel-post mounted upon said end, and a spring having one end joined to said swivel-post and the other end to said gate, substantially as described.

11. The combination of a hinge-post, the gate, the hinge-shaft, C, extended laterally at its upper end, a swivel-post mounted upon said end, a spring having one end joined to said swivel-post and the other end to said gate, and means for rotating said shaft so as to carry said swivel rearward and across the plane of the gate, substantially as described.

12. The combination of a hinge-post, the gate, the hinge-shaft, C, extended laterally at its upper end, a swivel-post mounted upon said end, a spring having one end adjustably joined to said swivel-post and the other end to said gate, and means for rotating said shaft so as to carry said swivel rearward and across the plane of the gate, substantially as described.

13. The combination of a crank-shaft, a rocking lever loosely secured to said crank-shaft and having arms extending away from said crank-shaft in opposite directions from the point of attachment between said lever and crank-shaft, a yoke mounted upon said crank-shaft and extending along one side of said rocking lever, substantially as described.

14. The combination of a rocking lever, a crank-shaft, and an adjustable yoke mounted upon said crank-shaft and surrounding said rocking lever, substantially as described.

15. The combination of a crank-shaft, a rocking lever loosely secured to said crank-shaft and having arms extending away from said crank-shaft in opposite directions from the point of attachment between said lever and crank-shaft, a yoke mounted upon said crank-shaft and extending along one side of said rocking lever, and mechanism applied to said yoke for restoring the crank-shaft to its normal position, substantially as described.

16. The combination of a rocking lever, a crank-shaft, an adjustable yoke mounted upon said crank-shaft and surrounding said rocking lever, and a spring applied to said yoke for restoring the crank-shaft to its normal position, and mechanism for varying the tension of said spring, substantially as described.

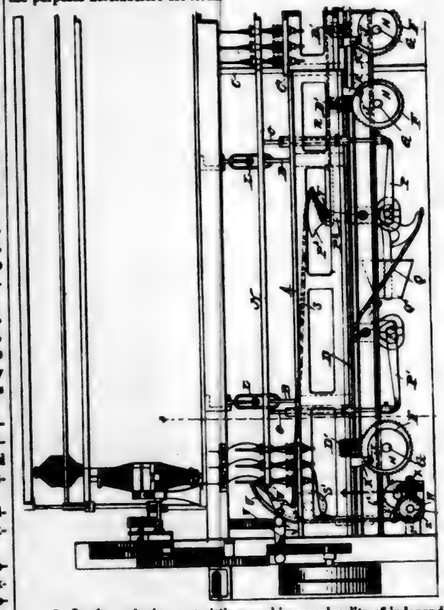
706,414. RING SPINNING AND TWISTING FRAME. ALFRED HITCHON, Accrington, England. Filed Mar. 14, 1902. Serial No. 98,342. (No model.)

Claim.—1. In ring spinning or twisting machines, a vertically-reciprocable spindle-carrying frame, in combination with pairs of reversely-placed and oppositely-revolving lifting-cams therefor, and projections on the said spindle-carrying frame upon which said cams operate, each of said projections being located above its cam and to one side of a vertical plane through the axis of said cam, substantially as and for the purposes hereinbefore set forth.

2. In ring spinning or twisting machines a series of independent vertically-reciprocable spindle-carrying frame-sections, a power-driven worm-shaft extending lengthwise of the spinning-frame and provided with pairs of right and left handed worms, one pair for each frame-section, two cross-shafts for each section provided the one with a right-handed worm-gear to engage the right-hand worm, and the other with a left-handed worm-gear to engage the left-hand worm, a pair of lifting-cams on each cross-shaft, the one pair being reversely placed relatively to the other pair, and projections on the spindle-frame sections, each located to one side of a vertical plane through the axis of its cam, substantially as and for the purposes hereinbefore set forth.

3. In ring spinning or twisting machines a vertically-reciprocable spindle-carrying frame, in combination with pairs of reversely-placed and oppositely-revolving lifting and descent-controlling cams, and coöperating projections upon the spindle-carrying frame, the projections pertaining to the lifting-cams being located to one side of a vertical plane through the axis of their respective cams, and those pertaining to the descent-controlling cams being located vertically over the centers of their respective cams, substantially as and for the purposes hereinbefore set forth.

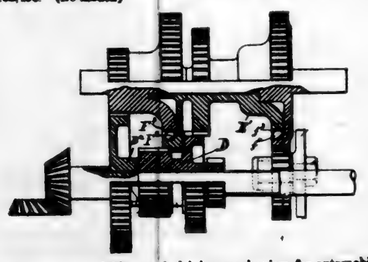
4. In ring spinning or twisting machines the combination of a number of independent vertically-reciprocable spindle-carrying frame-sections, and a series of sets of actuating-cams therefor located and adjusted substantially as herein described so that each individual spindle-carrying frame-section will move up and down in a step manner relative to its adjacent spindle-carrying frame section or sections, substantially as and for the purposes hereinbefore set forth.



5. In ring spinning or twisting machines a plurality of independent vertically-reciprocable spindle-carrying frame-sections, and a series of sets of actuating-cams therefor arranged and operating to cause each individual spindle-carrying frame-section to move upward and downward in a step manner relative to its adjacent spindle-carrying frame section or sections, in combination with coinciding sectional lengths of ring-rail, and mechanism whereby, during the vertical reciprocation of the spindle-sections, the rail-sections are gradually raised, substantially as and for the purposes hereinbefore set forth.

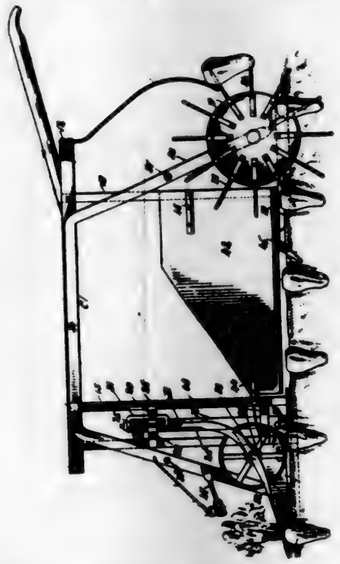
6. In ring spinning and twisting machines sectional spindle-carrying frames working in step manner relative to one another as described, coinciding lengths of ring-carrying rails, and means whereby, during the vertical reciprocation of the spindle-carrying sections the ring-rail sections are gradually raised in combination with a doffing-handle common to all the ring-rail sections and connections whereby when the handle is operated the several ring-rail sections are allowed to drop on their appropriate spindle-carrying sections, substantially as and for the purposes hereinbefore set forth.

706,415. DRIVING-GEAR FOR AUTOMOBILES. ALFRED HITCHON, Clayton-le-Dale, England. Filed Apr. 12, 1902. Serial No. 102,498. (No model.)



Claim.—In variable-speed driving mechanism for automobiles, the combination with the driving-shaft and the driven wheel, of a plurality of sets of free-wheel clutch devices, motion-transmitting means between the same and the driven wheel, independent gearing between each set of said free-wheel clutch devices and the driving-shaft, and means, operated by a single handle, for withdrawing said gearing from connection with each set of free-wheel clutch devices successively, beginning with that giving the highest speed, the driving-gears for all speeds below the one inactive remaining in operative connection with their respective free-wheel clutch devices, substantially as and for the purposes hereinbefore set forth.

706,416. BEET-HARVESTER. HIRAM S. HOUGHTON, Lyons N. Y. Filed Sept. 3, 1901. Serial No. 74,088. (No model.)



Claim.—1. In a beet-harvester, a frame adapted to travel over the surface of the ground, a guide carried by the frame, adapted to travel over the crowns of the beets, a top-separating finger carried by the support for the said guide and in advance of the said guide, and cutters mounted to rotate at the rear of said guide, said cutters being in pairs, the edges of the cutters in a pair being brought close together at a point at the rear of the said finger of the guide, substantially as described.

2. In a beet-harvester, a frame adapted to travel over the surface of the ground, a guide carried by the frame, adapted to travel over the crowns of the beets, a top-separating finger carried by the support for the said guide and in advance of the guide, cutters mounted to rotate at the rear of said guide, said cutters being in pairs, the edges of the cutters in a pair being brought close together at a point at the rear of the said finger of the guide, a yoke-frame carrying the said cutters, which yoke-frame has vertical guided movement in the main frame of the machine, and fingers carried by the main frame, which fingers enter the ground at opposite sides of the beets to be topped, for the purpose of loosening the soil around the topped beets, as described.

3. In a beet-harvester, the combination, with a main frame, a yoke located at the forward portion of the main frame, having vertical guided movement in said main frame, cutters mounted to turn at the bottom portion of the said yoke, which cutters have their peripheral edges brought close together at a point represented by a line drawn transversely through the cutters and frames, a shank adjustably carried by the said yoke, a guide-wheel carried by the said shank, adapted to travel in front of the meeting-point of the cutters, and a gathering device carried by the frame at the rear of the cutters, arranged to draw the beets from the ground, as and for the purpose set forth.

4. In a beet-harvester, the combination with a main frame, of a frame mounted to slide freely on the main frame, horizontally-arranged cutters mounted on the lower end of the sliding frame, a guide-wheel in advance of the cutting edges of the cutters, and a separating-finger in front of the guide-wheel, the wheel and finger being carried by a common support, as set forth.

5. In a beet-harvester, the combination with a main frame, of a frame mounted to slide freely in the main frame, horizontally-arranged disk cutters on the lower end of the sliding frame, a guide-wheel in advance of the cutting edges of the cutters, a separating-finger in front of the guide-wheel, and a support for the wheel and finger adjustably mounted in the sliding frame, as set forth.

6. In a beet-harvester, the combination with a main frame supported by runners at its front and at its rear, a yoke having vertical guided movement at the forward portion of the main frame, cutters mounted to revolve at the bottom portion of the said yoke, the cutters being in pairs, their cutting edges approaching each other closely at the longitudinal center of the frame, a shank adjustably carried by the said yoke, a guide-wheel carried by the said shank in advance of the meeting edge of the cutters, which wheel is adapted to travel over the crown of the beets from which the tops are to be cut, and a separating-finger carried by the shank of the guide-wheel and located in front of the said wheel, which finger is adapted to separate the tops of the beets in advance of the guide-wheel passing over their crowns, as set forth.

7. In a beet-harvester, the combination with a main frame, of a frame mounted to slide loosely in guideways of the main frame, a horizontally-arranged cutter on the lower end of each side member of the said frame, a shank adjustably secured to the frame carrying the cutters and having a curved lower portion, and a guide-wheel mounted in the curved portion of the shank, as set forth.

8. In a beet-harvester, the combination with a main frame, of a frame mounted to slide loosely in guideways of the main frame, horizontally-arranged cutters on the lower ends of the side members of the frame, a shank adjustably secured to the cutter-carrying frame and having a forwardly-curved lower portion, said curved portion being in two members which are brought together to form a finger, and a wheel mounted between the members of the shank, as set forth.

9. A beet-harvester, comprising a main frame mounted on runners, a frame mounted to slide freely in the main frame, horizontally-arranged disk cutters on the lower end of the sliding frame, a guide-wheel in advance of the cutting edges of the cutters, a separating-finger in front of the guide-wheel, a support for the wheel and finger adjustably mounted in the sliding frame, an auxiliary frame secured to the front and rear runners, and a gathering device mounted in the rear portion of the auxiliary frame, as set forth.

706,417. ENVELOP. JOHN B. HOWE, Windber, Pa. Filed May 12, 1902. Serial No. 106,885. (No model.)

Claim.—1. An envelop-seal consisting of a metal thimble having a covering of suitable fabric, and a disk having barbed prongs to penetrate said fabric and connect the disk with the thimble, substantially as described.

2. An envelop-seal consisting of two members, one having a diaphragm of fabric or like material, and the other having prongs to penetrate the envelop and said diaphragm to connect the members together, substantially as described.

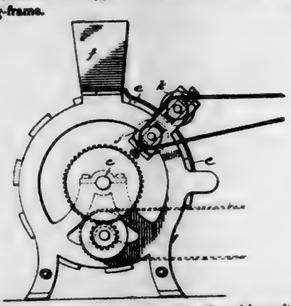
706,418. WASHING-MACHINE. ALEXANDER C. ISRAEL, Laporte, Tex. Filed Aug. 21, 1901. Serial No. 73,233. (No model.)

Claim.—In a washing-machine, the combination with the drum having intake-slots arranged at equidistances apart therein and projecting upwardly and out of line with the periphery of the drum, and transverse ribs secured below the slots, and transverse inclined boards arranged in rear of said slots, said ribs and said boards being spaced apart to form buckets between them, a cross-batched head at each end of the drum, and radial cross-arms at the other end of said drum, and the said cross-arms increasing in width from their central points of connection toward their outer ends, substantially as and for the purpose specified.

706,419. CROSS-CUTTING MACHINE. BENJAMIN S. JAYNE, New York, N. Y., assignor to Horace Craighead, Flushing, borough of Queens, N. Y. Filed Oct. 8, 1901. Serial No. 77,895. (No model.)

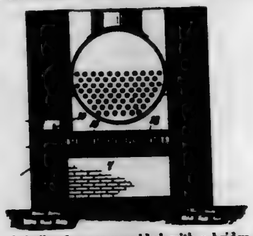
Claim.—1. In a stave-sawing machine, the combination with a suitable frame, and a main driving-shaft journaled therein, of two rotatable stave-carriers, each provided with corresponding peripheral seats to receive the staves, spring-pressed guides for normally holding the stave-blanks in said seats, a crosing-cutter and a chamfering-cutter mounted on

the same shaft, adjustable bearings for said shaft, a trimming-cutter mounted on an independent shaft on the same line radial to the stave-carrier as to the cross-cutter, adjustable bearings for said shaft, means for revolving the cutters, and a feed-hopper or magazine centrally located above the supporting-frame.



2. In a stave-crozing machine, the combination with a suitable frame, a stave magazine or hopper located centrally above said frame, and a main driving-shaft journaled therein, of two rotatable stave-carriers mounted on said shaft, each provided with corresponding peripheral seats to receive the staves, spring-pressed guides for normally holding the stave-blanks in said seats, a crozing-cutter and a chamfering-cutter mounted on a single shaft, adjustable bearings for said shaft, a trimming-cutter mounted on an independent shaft on the same line radial to the stave-carrier as to the cross-cutter, adjustable bearings for said shaft, means for adjusting the cutters carried on the single shaft and the cutter mounted on the independent shaft toward and from each other, mechanism for revolving the cutters, and mechanism for driving the main shaft.

706,420. SMOKE-CONSUMER. WILLIAM T. KROM, New York, N. Y. Filed Oct. 5, 1901. Serial No. 77,695. (No model.)

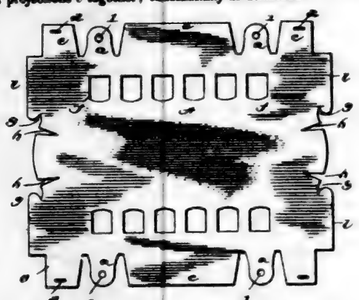


Claim.—1. A boiler-furnace provided with a bridge-wall having a rearwardly-inclined upper face, a metallic distributing member having an inclined side cast embedded in said bridge-wall for its inclined side only to be exposed through, and to lie in flush relation with, the inclined top face of said bridge-wall, said exposed inclined side of the member having a plurality of perforations, air and steam channels extending through a wall of the furnace, an air-supply tube located in the air-channel and coupled at a point intermediate of its length to one end portion of the distributing member, a combining-tube opening into the air-tube and extending into and surrounded by the distributing member, and a steam-pipe leading through the steam-flue and extending into the combining-tube.

2. A boiler-furnace provided with a bridge-wall, a distributing member having jet-perforations, an air-supply tube coupled at a point intermediate of its length to one end portion of the distributing member and having two open ends, a combining-tube united at one end to the air-tube and extending for the major portion of its length into a non-perforated portion of the distributing member, and a steam-pipe extending across the air-tube and into the combining-tube, whereby the combining-tube is protected by a surrounding chamber in, and the metallic portions of, the distributing member, and a small steam-pipe has its delivery end fitting loosely in a comparatively large combining-tube so as to provide for the unobstructed inward flow of the air-current through the open-ended air-tube.

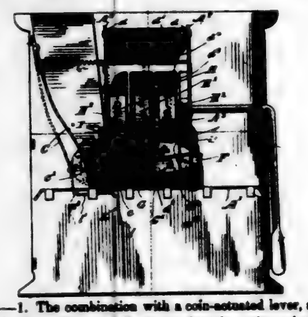
706,421. TOY. HARRY T. KINGSBURY, Keene, N. H. Filed Mar 8, 1901. Serial No. 49,989. (No model.)

Claim.—1. A toy car, composed of a single section bent to form a roof, and downwardly-projecting sides, said sides having inwardly-turned projections, *c* and *e*, said projections *e* being of length sufficient to substantially abut when bent inwardly; with means for securing said oppositely-placed projections *c* together; substantially as described



2. A toy car composed of a single section bent to form a roof, and downwardly-projecting sides, said sides having inwardly-turned projections provided with slits, and a T-clip *k*, the head of which is bent to enter the slits; and having its body portion extending beyond the end of the blank and provided with an opening to receive a coupling-link, substantially as described.

706,422. TOY BANK. HARRY T. KINGSBURY, Keene, N. H. Filed Sept. 21, 1901. Renewed June 4, 1902. Serial No. 110,180. (No model.)



Claim.—1. The combination with a coin-actuated lever, and a registering mechanism, of a manually-operated latch-carrier, a latch carried thereby to connect the said carrier with the registering mechanism, and a connection between the coin-operated lever and said latch to throw it into its operative position; substantially as described.

2. The combination with a coin-actuated lever, and a registering mechanism including a plurality of registering wheels or disks and their operating rack-bars, of a manually-operated latch-carrier, a latch mounted on the said carrier and toothed for engagement with said rack-bars, and operative connections between the said coin-actuated lever and the latch to throw it and bring the proper teeth into operative relation to the rack-bars; substantially as described.

3. The combination of an open-sided coin-chute, and a coin-operated lever along the open side of the chute, a manually-operated latch-carrier; a latch mounted on said carrier, means for operating the latch from the coin-lever, of registering-wheels provided with shouldered operating-bars adapted to be connected with and thrown by the manually-operated carrier when its latch is thrown into operative position by a coin; substantially as described.

4. The combination with the tapered open-sided coin-chute, a coin-operated lever along the open side of the chute, and a registering mechanism including a plurality of registering-wheels provided with shouldered operating-bars, of a manually-operated carrier to swing along said operating-bars, a latch mounted on the carrier and toothed to engage said shouldered bars and connect the carrier therewith, and an operative connection between the coin-actuated lever and the latch for throwing it into its operative position; substantially as described.

5. The combination with the tapering coin-chute open at one side, a coin-operated lever along the open side of the slot for varying throw by coins of different diameter, and a registering mechanism including a plurality of registering-wheels and shouldered operating rack-bars, of a pivoted manually-operated latch-carrier mounted to swing along said rack-bars, a latch pivoted at the lower free end of the carrier and having graduated teeth on its lower edge, a rod for connecting said latch with the coin-actuated lever to swing the latch and bring the proper teeth into the path of the rack-bar shoulders and so connect said bars with the carrier; substantially as described.

6. The combination with the tapering coin-chute open at one side, a coin-operated lever along the open side of the slot for varying throw by coins of different diameter, and a registering mechanism including a plurality of registering-wheels and shouldered operating rack-bars, of a pivoted manually-operated latch-carrier crossing said rack-bars and movable along the same, a latch pivoted to the lower end of the said carrier with its lower edge provided with graduated teeth for engaging the shoulders on the rack-bars, a spring-pressed cranked arm pivoted on the said carrier with one of its cranks forming the pivot of the latch and extended through the carrier for engagement with the back plate to release the latch, and a rod extending from the plate and bent to pass behind the coin-lever for operation thereby; substantially as described.

7. The combination with an open-sided coin-chute, a lever along the open side of the chute, and a registering mechanism including registering-wheels provided with operating-bars, of a manually-operated carrier to swing along said bars and provided with a latch to connect it with the said bars, and a rod for connecting the latch with the coin-lever, the lower edge of the carrier having a flange to temporarily support the coin in the chute; substantially as described.

8. A toy bank comprising a body having a removable wall, a partition and framework secured to said wall, of an open-sided chute secured to said wall and registering at its upper end with a coin-inlet in the top and at its lower end registering with a coin-outlet in the partition, a lever along the open side of said chute, a registering mechanism mounted on said framework and including registering-wheels exposed through a front opening and provided with rack-bars, a forwardly-swinging latch-carrier pivoted at its upper end to said removable wall and swinging over the rack-bars, a lever for operating said carrier from the exterior of the bank, a latch pivoted to the carrier and having a graduated toothed lower edge to engage the respective rack-bars and connect them to said carrier for operation thereby; and a rod for connecting the said latch with the coin-actuating lever; substantially as described.

9. The combination with the toothed registering-wheels, and rack-bars for operating them, pins on the wheels, and lugs or shoulders on the rack-bars in the path of said pins, and a coin-controlled actuating mechanism for throwing the rack-bars; substantially as described.

10. The combination with a coin-actuated lever and a registering mechanism including toothed wheels, each having a pin and operating rack-bars, each having a shoulder at its forward end for engagement by the said pins and a retracting-shoulder at its rear end, of a forwardly-swinging manually-operated latch-carrier having slots at its lower end, receiving the rear shouldered ends of the rack-bars, a latch on the carrier having a graduated toothed lower edge to engage the rack-bars for forward throw by the carrier, and a rod for connecting the latch with the coin-actuated lever; substantially as described.

11. The combination with the registering-wheels and their operating rack-bars, of a manually-operated latch-carrier extending over said bars and provided with a coin-actuated latch for operatively connecting it with the rack-bars; substantially as described.

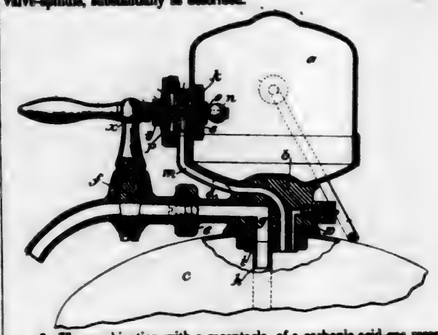
12. The combination with the registering mechanism, provided with shouldered operating-bars, of a manually-operated latch-carrier extending over said bars and provided with a coin-actuated latch for operatively connecting it with said rack-bars, means for holding the latch in its operative position, and means for releasing the latch and restoring the same to its normal inactive position; substantially as described.

13. The combination with a manually-operated carrier or arm and a series of devices for operation by said carrier or arm, of a coin-operated latch mounted on said carrier or arm and provided with graduated teeth thrown into operative relation with one or more of said series of devices according to the distance the latch is moved by coins of different diameters: substantially as described.

706,428. SIPHON FOR DISPENSING LIQUIDS. ARTHUR KLEINFELDT, New York, N. Y. Filed Jan. 23, 1901. Serial No. 44,441. (No model.)

Claim.—1. A carbonic-acid-gas reservoir provided with a neck portion whereby said reservoir may be secured to a receptacle, a passage in said neck portion providing a means for filling the reservoir and for supplying gas to the interior of the receptacle, a valve in said passage provided with a spindle engaging a yielding packing, a faucet communicating with the interior of the receptacle provided with a handle operatively engaging said spindle when the faucet is opened and closed to reciprocate the same and open and close the valve, and means for normally holding said valve closed but permitting the valve to be opened automatically by the pressure of the incoming gas when the receptacle is charged through said passage.

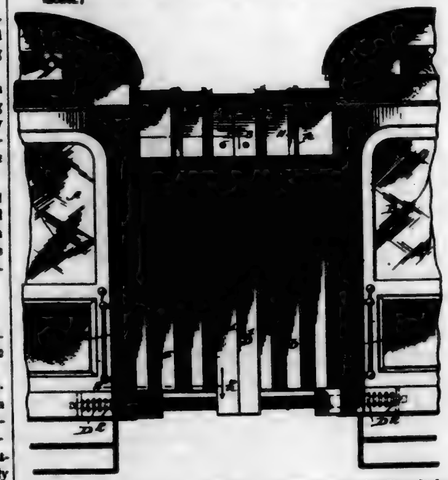
2. The combination with a receptacle, of a carbonic-acid-gas reservoir having an outlet communicating with said receptacle, a valve controlling said outlet, means for normally closing said valve, a plunger in alinement with the spindle of said valve, whereby said valve is actuated, a faucet communicating with the interior of the receptacle provided with a handle engaging with said plunger when the faucet is open to reciprocate same, and a yielding packing interposed between said plunger and valve-spindle, substantially as described.



3. The combination with a receptacle, of a carbonic-acid-gas reservoir having an outlet communicating with said receptacle, a valve controlling said outlet, a spring for holding said valve in its closed position, a plunger engaging said valve to open same against the resistance of the spring, a faucet communicating with the receptacle having a handle engaging with said plunger when the faucet is partly open to reciprocate same and open the valve, and a yielding packing interposed between said plunger and the valve-spindle, substantially as described.

4. The combination with a receptacle, of a carbonic-acid-gas reservoir having an outlet communicating with said receptacle, a valve on the interior of said receptacle for controlling said outlet, a spring for holding said valve in its closed position, a plunger arranged to actuate the spindle of said valve, a faucet communicating with the interior of the receptacle having its handle provided with an irregular cam engaging said plunger to move same varying distances, an elastic diaphragm to prevent the escape of the gas through the opening for said plunger, and a yielding packing interposed between said plunger and the valve-spindle, substantially as described.

706,424. METALLIC HOOD FOR VESTIBULES OF CARS. JAMES M. KNAUS, Sedalia, Mo. Filed Apr. 16, 1902. Serial No. 103,219. (No model.)



Claim.—1. A hood for vestibuled cars comprising a plurality of telescoping sections, a flap-plate secured to the outer section, means for holding the hood yieldingly distended, and means for securing the inner section to the vestibule with freedom to give laterally to the motion of the car, substantially as described.

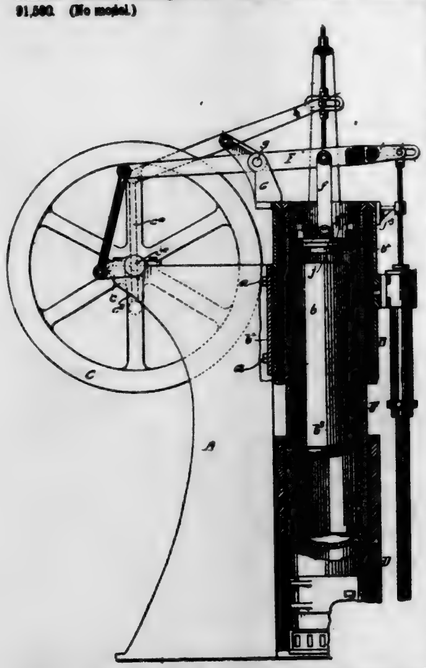
2. A hood for vestibuled cars comprising a plurality of telescoping sections, a slotted plate secured to the inner section and adapted to rest against the outside of the frame of the vestibule, cleat-plates adapted to be secured to the vestibule to overlap the edges of the slotted plate and pins adapted to be passed through the slots of the slotted plate into the frame of the vestibule, substantially as described.

3. A hood for vestibuled cars comprising a plurality of telescoping sections, the two inner sections being composed of metallic plates doubled back and under exposing only the rounded folded edge, a face-plate secured to the outer section, means for holding the sections yieldingly in their extended position, and means for limiting such outward extensions, substantially as described.

4. A hood for vestibuled cars, comprising a plurality of telescoping sections, each overlapping section consisting of a plate of metal folded back and under, the under fold being slotted longitudinally of the car, means for yieldingly maintaining the sections extended, and pins passing through the interior sections into the slots in the inner folds of the exterior sections to limit the outward movement of the sections on each other, substantially as described.

5. A hood for vestibuled cars comprising a plurality of telescoping sections, a strip of metal secured to the edge of each overlapping or exterior section, bent to form a pocket facing the interior section, and a strip of flexible material, having one edge secured in said pocket and its other edge bent outward and resting on the exterior of the interior section, substantially as described.

706,425. HOT-AIR PUMPING-ENGINE. JOHN T. LALLY and JAMES J. ENGLISH, Wilmington, Del. Filed Jan. 28, 1902. Serial No. 91,592. (No model.)



Claim.—1. In a hot-air engine, the combination of a frame, a cylinder supported thereon, having working and transfer pistons, means for heating the cylinder, a fly-wheel and a shaft therefor, with two levers connected to said shaft both pivotally supported above the top of the engine-cylinder and connected respectively to the working and to the transfer pistons, substantially as described.

2. In a hot-air engine, the combination of a frame, a cylinder supported thereon having working and transfer pistons, means for heating the cylinder, a fly-wheel and a shaft therefor, two cranks on the shaft, two levers supported over the cylinder each having a connecting-rod operatively attaching it to one of the cranks, one of the levers being connected to the transfer-piston and the other being connected to the working piston and to mechanism operated by the engine, substantially as described.

3. In a hot-air engine, the combination of a cylinder, means for heating the same, working and transfer pistons in the cylinder, a fly-wheel, a shaft therefor, two levers each connected to the fly-wheel shaft, one of the levers having a projecting portion or arm turned parallel to the body thereof and with said body connected to one of the pistons, the other lever extending between the said two parts of the first lever and being connected to the other piston, substantially as described.

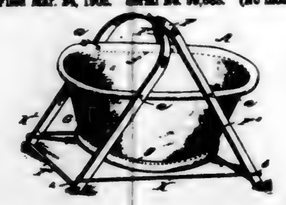
4. In a hot-air engine, the combination of a cylinder, means for heating the same, working and transfer pistons in the cylinder, a fly-wheel, a shaft therefor, two levers each connected to the fly-wheel shaft, one of the levers having a projecting portion or arm turned parallel to the body thereof, and with said body connected to one of the pistons, the other lever being also forked and having a pin extending between the arms of its forked end with a rod connected to the second piston having a slotted block in engagement with said pin, substantially as described.

5. In a hot-air engine, the combination of a cylinder means for heating the same, working and transfer pistons in the cylinder, a fly-wheel, a shaft therefor, two levers each connected to the fly-wheel shaft, means for connecting one of the levers to one of the pistons, a piston-rod attached to the other piston and provided with a slotted block, a guide supported from the cylinder-casting and in engagement with said rod, the second lever being provided with means whereby it is attached to the rod through said slotted block, substantially as described.

6. In a hot-air engine, the combination of a cylinder, means for heating the same, working and transfer pistons in the cylinder, a fly-wheel, a shaft therefor, two levers supported above the cylinder, one of the same carrying a roller, a rod attached to one of the pistons carrying a slotted block engaged by said roller, the second lever provided with a projecting arm bent parallel with the body thereof, links connecting the second piston with the said arm and body of the second lever and an extension to said lever having means whereby it may be connected to mechanism to be operated, substantially as described.

7. In a hot-air engine, the combination of a cylinder, means for heating the same, working and transfer pistons in the cylinder, a fly-wheel, a shaft therefor, two levers each connected to the fly-wheel shaft, one of the levers having means for connecting it to the transfer-piston, the other lever being connected to the working piston and provided with an extension beyond the point of said connection, a pump having a piston-rod with a slotted block operatively connected to said extension, with means for guiding said rod supported from the cylinder-casing, substantially as described.

706,426. FOLDING BASKET. THOMAS J. LANGSTON, Johnston, S. C. Filed Mar. 24, 1902. Serial No. 99,653. (No model.)



Claim.—1. The improvement in baskets herein described consisting of, the basket-body having top and bottom rim-frames, a flexible separable bottom, a free frame for said bottom having its edges secured to a rim-frame with said separable bottom adjusted inside the flexible body above its bottom rim-frame, a draw-string around the flexible body above said separable bottom, a stitched-in flexible bottom above said removable bottom, handle-frames having their side bars pivoted to the top rim-frame of basket-body and extending below the bottom of said body forming legs, cross-braces for said legs, guides on the legs for tension-lines, the tension-lines carried in and through said guides and secured at their ends to the rim-frame of the flexible bottom, and a latching device for the handle-frame consisting of a staple on one frame, a cooperating staple on the other frame, and a bolt for locking the staples together, substantially as described.

2. The combination of a flexible collapsible basket-body having top and bottom rim-frames, a removable bottom over and under a free frame with the edges of said removable bottom secured to a rim-frame, a draw-string around the flexible body above the flexible removable bottom, the handle-frames having their side bars pivoted to the top rim-frame of the basket-body and extending below the bottom of said body and forming legs, braces for said legs, guides on the legs for tension-lines, the tension-lines extending through said guides and secured at their ends to the bottom rim, substantially as described.

3. In a basket the combination of a flexible body having top and bottom rim-frames, a stitched-in flexible bottom above the bottom rim-frame, the handle-frames having their side bars pivoted to the top rim-frame of the basket-body and extending below the bottom forming legs, braces for said legs with guides for tension-lines, and tension-lines passing through said guides and secured at their ends to the bottom rim of the basket-body substantially as set forth.

4. A flexible basket-body having a top rim-frame, a pair of bow handle-frames having their side bars pivoted to said rim-frame and extending below the basket-body forming legs therefor, straps, or lines, connecting the legs and bottom of flexible basket-body, and a latching device for the crowns of the bow-handles consisting of a bolt, guides therefor and interlocking staples arranged to bolt the basket in open position, substantially as described.

5. The combination of a flexible basket-body, the rim-frames at the top and bottom thereof, a stitched-in flexible bottom above lower frame, handle-frames having their side bars pivoted to upper frame of basket-body, and extending at their lower ends below the basket-body forming legs and the latching devices for the crowns of the handle-frames substantially as described.

6. In a basket the combination with the basket-body and the handle-frames having their side bars pivoted to the basket-body and extending below the same, and provided with guides for line connections and the line connections passing through said guides and connected at their ends to the basket-body, substantially as set forth.

7. A flexible basket-body provided with a flexible bottom, and below the same with a flexible false bottom, substantially as set forth.

8. The flexible basket-body provided with a flexible removable bottom and with a frame by which the bottom is held in said body substantially as set forth.

9. The combination with a flexible basket-body having a flexible bottom, of a draw-string applied around the body adjacent to the bottom, substantially as set forth.

10. The combination of a flexible basket-body, the rim-frame at the upper and lower ends thereof, a flexible false bottom above the lower frame and a draw-string applied to the body above the false bottom, substantially as described.

11. The combination of a flexible basket-body, the rim-frames at the upper and lower ends thereof and a flexible stitched-in bottom between the upper and lower frames, and the false bottom between the stitched-in bottom and the lower free frame, substantially as set forth.

12. The combination of a flexible basket-body, having a rim-frame and a support-frame pivoted to the side bars of bow handle-frames, with said side bars of handle-frames extending below the bottom of flexible basket-body forming legs therefor, line connections between the legs and bottom of flexible basket-body, and a latching device for the crowns of the bow-handles, substantially as described.

13. The improvement in baskets herein described consisting of the basket-body having the top frame and the bottom frame and provided with the flexible bottom and with a draw-string and a casing therefor and having an extension below said bottom, the handle-frames having their side bars pivoted to the body of the basket and extending below the bottom of said body to form legs and provided with guides for the line connections, and the line connections carried through said guides and secured at their ends to the body of the basket, substantially as set forth.

14. The combination of the flexible body having a flexible bottom and an extension below the same, and a lower rim-frame and bracing or false bottom operating in connection with said lower extension substantially as set forth.

15. The combination of the flexible basket-body having a bottom and below the same an extension and the lower rim-frame held in said extension, the free frame D in said extension above the lower and rim frame, and the false bottom passed over said free frame and secured substantially as set forth.

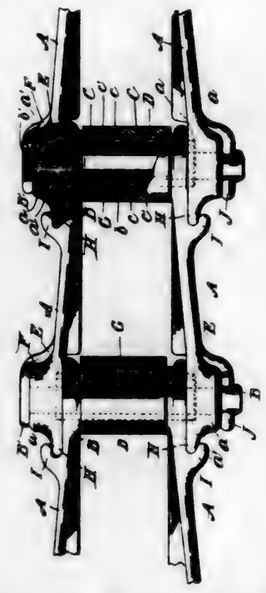
16. The combination with the flexible basket-body having a flexible bottom and an extension below the said bottom, the rim-frame held in said extension, and the flexible bracing or false bottom held to said rim-frame, substantially as and for the purposes set forth.

706,427. DRIVE-CHAIN. CHRISTOPHER W. LEVALLEY, Milwaukee, Wis. Filed June 11, 1901. Serial No. 64,157. (No model.)

Claim.—1. A chain formed of links having side bars and hollow end bars of cast metal, and interior and exterior wearing-sleeves of steel for the end bars, substantially as set forth.

2. A chain formed of links having side bars and hollow end bars of cast metal, the side bars of each link being separate from each other, and interior and exterior wearing-sleeves of steel for the end bars, substantially as set forth.

3. A chain comprising links having side bars and divided hollow end bars carried by the side bars, and tubular connecting parts having tight-fitting engagement with the divided end bars arranged to rigidly connect the opposite side bars, substantially as set forth.



4. In a chain, the combination with the side bars, the divided tubular end bars carried by the side bars, removable bushings fitting tightly within the end bars and uniting the opposite side bars and cross-bolts extending through the side bars and end bars and uniting the adjacent links, substantially as set forth.

5. In a chain, the combination with the side bars, the divided tubular end bars carried by the side bars, the removable bushings within the tubular end bars and having their ends extended outward and arranged to have interlocking engagement with the side bars, and means for preventing the side bars from spreading laterally, substantially as set forth.

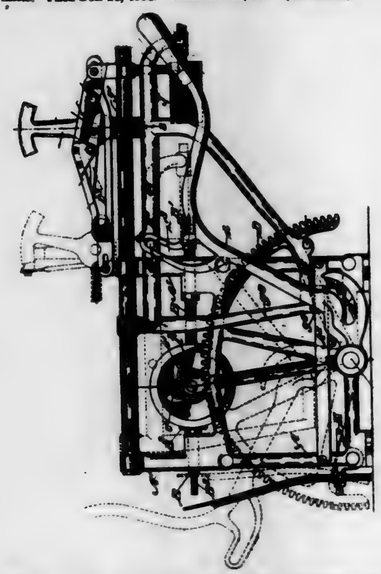
6. In a chain, the combination of the side bars, each bar being provided with an inward-extending tubular portion C, such tubular portions of the opposite side bars being arranged to be brought together, end to end, to form a hollow or tubular end bar, and a sleeve adapted to fit tightly over the said tubular portions C, and rigidly hold them together and also to constitute wearing-surfaces for the sprocket-teeth to engage with, substantially as set forth.

7. In a chain, the combination of the side bars provided with inward-extending tubular portions C, such tubular portions of the opposite side bars being arranged to be brought together, end to end, to form hollow tubular end bars, bushings fitting tightly within the said hollow end bars, and arranged to constitute internal wearing-surfaces for the end bars, and also to rigidly connect and hold together the opposite side bars, connecting bolts or pins arranged to unite adjacent links and have wearing engagement with the said bushings, and means for preventing the connecting-bolts from rotating relative to the side bars through which they pass, substantially as set forth.

8. In a chain formed of articulated links, the combination of the side bars of the links, the divided end bars carried by the side bars and formed with interlocking parts, the sleeves fitting the end bars tightly and arranged to unite and rigidly hold together the parts of the divided end bars and the opposite side bars, and means for connecting the links at the joints of the chain, substantially as set forth.

9. In a chain, the combination of the side bars each provided with an inward-extending tubular portion C, the tubular portions of opposite side bars being arranged to be brought together, end to end, to form hollow or tubular end bars, bushings D fitted tightly within the hollow end bars, sleeves G fitted tightly upon the exterior of the said end bars, the said bushing and sleeves constituting interior and exterior wearing-surfaces of the end bars, and operating to unite the opposite side bars, and connecting cross pins or bolts which pass through the side bars and the end bars and unite the links at the joints thereof, substantially as set forth.

706,428. APPLE CORER AND PARER. JOSEPH P. MASSEY, Allegan, Mich., assignor of one-half to Theodore S. Updyke, Allegan, Mich. Filed Dec. 21, 1901. Serial No. 86,815. (No model.)



Claim.—1. In an apple-parer, the combination of the fork and means for rotating it, a reciprocating frame, a vertical shaft carried by said frame, a knife-head-supporting rod suspended from said shaft, a spring for holding and drawing said rod toward the shaft, and a guide for the rod; with a crank pivoted beside the shaft, a gear on the upper end of the shaft, a sector on the upper arm of the crank meshing therewith, a pin on the short arm of the crank, and a stationary plate having a guide-slot traversed by said pin, substantially as and for the purpose described.

2. The combination of the fork and means for rotating it; with a reciprocating frame, the knife-supporting shaft carried thereby, a segment on the end of said shaft, a sector meshing with said segment, a bell-crank carrying said sector, on one arm and having a pin on its other arm, a stationary plate having a guide-slot traversed by said pin, and a cam pivoted in said guide-slot adapted to cause the proper oscillation of the crank when the frame moves toward the fork, substantially as described.

3. The combination of the rotatable tubular shaft, the core-ejector therein, the bevel-gears for rotating the tubular shaft, the sector, pinion and clutch for operating the gears, the pivoted stop for the sector, the lever attached to the stop adapted to actuate the core-ejector when the stop is struck by the sector; with a reciprocating frame, the coring-blade thereon, the knife-supporting shaft carried by said frame, a gear on the end of said shaft, a segment meshing with said gear, a bell-crank carrying said segment on one arm and having a pin on its other arm, a stationary plate having a guide-slot traversed by said pin, and a cam pivoted in said guide-slot and an oscillating lever and connections for operating the sector and said frame, all substantially as and for the purpose set forth.

4. The combination of a rotatable fork, a reciprocating frame, a cutter-head carried by said frame, means for partially turning said cutter-head during the paring operation, and for stopping its rotation on its return stroke, and a reciprocating lever and connections for operating said carriage and rotating said fork from such lever, substantially as described.

5. The combination of a rotatable fork, a reciprocating frame, a cutter-head carried by said frame, means for partially turning said cutter-head during the paring operation, and for stopping its rotation on its return stroke, and a reciprocating lever and connections for operating said carriage and rotating said fork from such lever; with a coring-knife rigidly attached to said frame in rear of the cutter-head, and adapted to core the fruit simultaneously with the paring operation, substantially as described.

6. In an apple-paring machine, the combination of the movable frame, a rotatable shaft mounted thereon, the knife-head suspended from and rotatable with the shaft, a segment on the shaft, a sector meshing with the segment, and a vibrating arm carrying the sector having a pin; with a slotted plate beside the path of the sector having a slot adapted to be traversed by said pin to rock the arm, and a cam adapted to engage the pin and rock the sector during the paring operation, substantially as described.

7. In an apple-paring machine, the combination of the rotatable shaft, the fork on one end thereof, the bevel-gear and pinion for actuating said shaft, a vibrating segment, a pinion meshing with said segment, and clutch devices between said pinion and gear; with a reciprocating frame, the paring devices thereon and a rocking lever connected to the segment having open-ended cam-slots adapted to alternately engage pins on the frame and reciprocate the latter, said slots and pins imparting different speed to the frame in its strokes, substantially as described.

8. In an apple-paring machine, the combination of the rotatable fork, a reciprocating frame, the coring and paring devices mounted thereon; a rocking lever provided with open-ended cam-slots at different distances from its pivot, and studs on the frame adapted to be respectively engaged and disengaged by the cam-slots of the lever on each stroke of the frame, for the purpose and substantially as described.

9. In an apple-parer, the combination of the sliding frame, a rotatable shaft mounted thereon, the knife-head suspended from said shaft, a segment on the shaft, a sector meshing with the segment, and a rocking arm carrying the sector on one end and having a pin on the other end; with a slotted guide-plate beside the path of the sector having a slot adapted to be traversed by said pin, and a cam-plate pivoted in the slot and adapted to engage the pin and rock the sector during the paring operation, substantially as described.

10. The combination of the rotary shaft carrying a fork, the oscillating segment and gearing for rotating said shaft, and a rocking lever for oscillating said segment provided with open-ended cam-slots at different distances from its pivot; with a reciprocating frame movable to and from the fork, provided with studs respectively adapted to be successively engaged and disengaged by the corresponding cam-slots of the lever on each stroke of the frame to impart different speeds to the latter, substantially as described.

11. The combination of the rotary shaft carrying a fork, the oscillating segment and clutch-gearing for rotating said shaft, and a rocking lever for oscillating said segment provided with upper and lower open-ended cam-slots; with a reciprocating frame movable to and from the fork, provided with upper and lower studs adapted to alternately and respectively engage and disengage the cam-slots of the lever on each stroke of the frame to impart different speeds thereto, and the paring and coring devices mounted on and movable with said frame substantially as described.

12. The combination of the rotary shaft carrying a fork, an oscillating lever having two open cam-slots at different distances from its pivot, clutch-gearing actuated by said lever for rotating said shaft, and means for ejecting the core upon the completion of the paring and coring operations; with a reciprocating frame movable to and from the fork, upper and lower studs on said frame adapted to alternately engage the slots on the lever on each stroke of the frame to impart different speeds thereto, and the paring and coring devices mounted on and movable with said frame all substantially as and for the purpose described.

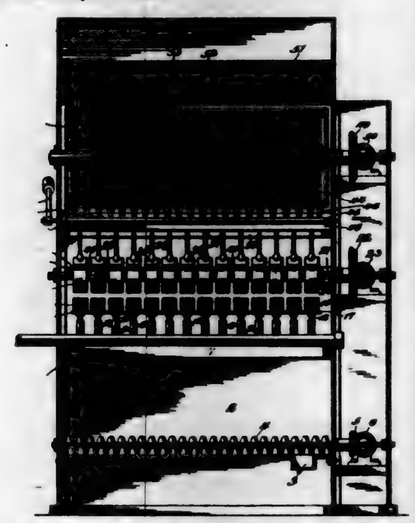
13. In an apple-parer, the combination of the fork and means for rotating it, a reciprocating frame, a vertical shaft carried by said frame, a knife-head suspended from said shaft, a controlling-spring for the knife-head, and a guide therefor, a crank pivoted beside the shaft, a sector on one end of the crank meshing a gear on the shaft, and a pin on the other arm of the crank; with a stationary plate having a guide-slot traversed by said pin and a cam pivoted in said slot, substantially as and for the purpose described.

706,429. LAMPBLACK APPARATUS. JOHN L. MANN, Smithton, W. Va., assignor to the Castle Brook Carbon Black Company, Williamsport, Pa. Filed Feb. 3, 1902. Serial No. 92,445. (No model.)

Claim.—1. In an apparatus for making carbon-black, the combination with means for producing carbon, of carbon-collecting means made up of a substantially horizontal series of members mounted to rotate in individual substantially parallel vertical planes which are separated by vertical interspaces, each member being arranged with its peripheral edge in coöperative relation with the carbon-producing means and provided with opposite flat unbroken heads or ends forming collecting-surfaces, and scrapers for the heads of the collecting members.

2. In an apparatus for making carbon-black, the combination with carbon-producing means, of carbon-collecting means made up of a substantially horizontal series of wheels mounted to rotate in individual substantially parallel vertical planes which are separated by vertical interspaces, each member being disposed above the carbon-producing means with its periphery in coöperative relation therewith, and provided with opposite flat unbroken heads or ends which are flush throughout with the respective sides of the periphery of the wheel and forming carbon-collecting surfaces, and scrapers disposed across the heads to scrape carbon therefrom.

3. In an apparatus for making carbon-black, the combination with carbon-producing means, of a plurality of vertically-disposed rotatable carbon-collecting wheels separated by vertical interspaces and having opposite flat carbon-collecting heads, and scrapers located between the carbon-collecting wheels, each scraper being in operative relation to the opposite faces of adjacent wheels.



4. In an apparatus for making carbon-black, the combination with a casing, and carbon-producing means housed thereby, of a vertically-disposed rotatable carbon-collecting wheel located above the carbon-producing means and having a flat carbon-collecting head, and a relatively fixed scraper in operative relation to the flat carbon-collecting head of the wheel and having its opposite ends supported at opposite sides of the casing.

5. In an apparatus for making carbon-black, the combination with a casing, and carbon-producing means housed therein, of a plurality of vertically-disposed rotatable carbon-collecting wheels having opposite flat carbon-collecting heads and separated by vertical interspaces, scrapers located in the interspaces in frictional engagement with the opposite heads of adjacent wheels, and scraper-supports carried by opposite sides of the casing, the opposite ends of the scrapers being carried by the respective supports.

6. In an apparatus for making carbon-black, the combination with a casing, and carbon-producing means housed therein, of a plurality of vertically-disposed rotatable carbon-collecting wheels mounted upon a common axis and provided with opposite flat carbon-collecting heads, the wheels being separated by vertical interspaces, notched supports carried by the casing and located at opposite sides of the wheels, and scrapers located in the interspaces between the wheels to scrape the heads thereof and having their opposite ends seated in the corresponding notches of the opposite supports.

7. In an apparatus for making carbon-black, the combination with carbon-producing means, of a rotatable shaft located adjacent to the same, a plurality of rotatable carbon-collecting wheels mounted upon the shaft and having their hubs projected at corresponding ends to form spacing devices for the wheels, the latter also having opposite flat carbon-collecting heads, and scrapers located in the spaces between the wheels and in operative relation to the heads thereof.

8. In an apparatus for making carbon-black, the combination with carbon-producing means, of a rotatable shaft located adjacent thereto, a plurality of hollow carbon-collecting wheels mounted thereon, each wheel having one flat integral carbon-collecting head, a hub projected beyond the opposite side of the wheel, and a separate flat carbon-collecting head applied to that side of the wheel having the projected hub portion forming a spacing device for the adjacent wheels, and scrapers situated in the spaces between the wheels and in operative relation to the adjacent heads thereof.

9. An apparatus for making carbon-black, having carbon-producing means, in combination with carbon-collecting means made up of a plurality of carbon-collecting wheels mounted to rotate in substantially parallel individual planes which are separated by interspaces, each wheel consisting of a hollow casting, and a flat unbroken head secured to one end of the wheel and forming a carbon-collecting surface.

10. In an apparatus for making carbon-black, the combination with carbon-producing means, of a hollow rotatable carbon-collecting wheel in operative relation thereto, and provided upon its inner periphery with integral ribs disposed transversely of the rim thereof, and a flat circular carbon-collecting head secured to corresponding ends of the ribs.

11. An apparatus for making carbon-black having carbon-producing means, in combination with carbon-collecting means made up of a plurality of carbon-collecting wheels mounted to rotate in substantially parallel individual planes which are separated by interspaces, each wheel consisting of a hollow cylindrical casting having one integral head, and a separate flat unbroken head secured to the opposite end of the casting, both heads forming carbon-collecting surfaces.

12. In an apparatus for making carbon-black, the combination with carbon-producing means, of a rotatable shaft located adjacent thereto, a plurality of carbon-collecting wheels mounted thereon, each wheel comprising an open-ended cylinder having one flat integral carbon-collecting head, a hub projected at the opposite side of the wheel, integral ribs upon the inner periphery of the wheel, and a flat carbon-collecting head closing the open side of the wheel and secured to the adjacent ends of the ribs, fastening means engaging the projected ends of the hubs to connect the wheels to the shaft, said projected hub portions forming spacing devices to separate the wheels, and scrapers located in the spaces between the wheels and in operative relation to the heads thereof.

13. In an apparatus for making carbon-black, the combination with a casing and carbon-producing means housed therein, of a rotatable shaft located above the carbon-producing means, a plurality of vertically-disposed carbon-collecting wheels mounted upon the shaft, each wheel having one flat integral carbon-collecting head, a hub projected at the opposite side of the wheel, the projected portion of the hub bearing against the head of the next adjacent wheel and forming a spacing device to separate the two wheels, a separate flat carbon-collecting head applied to the open side of the wheel, fastening means connecting the respective projected hub portions to the shaft, individual scrapers in operative relation to the peripheries of the respective wheels, supports carried by the frame and located at opposite sides of the shaft, and scrapers having their opposite ends carried by the supports and their intermediate portions located in the spaces between the wheels and in operative relation to the heads thereof.

14. In an apparatus for making carbon-black, the combination with a collecting-surface, of carbon-producing means embodying a burner, and flame-confining means embracing the burner and adjustable toward and away from the carbon-collecting surface independent of the burners.

15. In an apparatus for making carbon-black, the combination with a carbon-collecting surface, of a burner which is adjustable toward and away from said surface, and a flame-confining device embracing the burner and adjustable toward and away from the collecting-surface independently of the adjustment of the burner.

16. In an apparatus for making carbon-black, the combination with a collecting-surface, of a burner in coöperative relation thereto, and an open-ended flame-confining device which is adjustable toward and away from the collecting-surface.

17. In an apparatus for making carbon-black, the combination with a carbon-collecting surface, of a carbon-producing burner, and an open-ended perforate flame-confining device embracing the burner and adjustable toward and away from the collecting-surface.

18. In an apparatus for making carbon-black, the combination with a collecting-surface, of a carbon-producing burner, and a flame-confining device carried by the burner and adjustable thereon toward and away from the carbon-collecting surface.

19. In an apparatus for making carbon-black, the combination with a carbon-collecting surface, of a carbon-producing burner having a screw-threaded part, and a flame-confining device embracing the burner and connected to the screw-threaded part thereof for adjustment toward and away from the carbon-collecting surface.

20. In an apparatus for making carbon-black, the combination with a carbon-collecting surface, of a carbon-producing burner having a screw-threaded part, a nut adjustably applied to the screw-threaded part, and a flame-confining device supported upon the nut and adjustable therewith toward and away from the collecting-surface.

21. In an apparatus for making carbon-black, the combination with a carbon-collecting surface, of a carbon-producing burner having a screw-threaded part, a nut adjustably applied to said screw-threaded part, and a flame-confining device having a cross-bar which is provided with an opening receiving the burner with the cross-bar supported upon and adjustable with the nut.

22. In an apparatus for making carbon-black, the combination with a collecting-surface, of a carbon-producing burner having an intermediate tip and opposite terminal tips, the outer tips being externally screw-threaded, nuts applied to the screw-threaded tips, and a flame-confining device embracing the tips and provided with a pair of cross-bars having open-

ings receiving the terminal tips with the cross-bars supported upon and adjustable with the nuts.

23. In an apparatus for making carbon-black, the combination with a carbon-collecting surface, of a carbon-producing burner having an intermediate tip and opposite externally-screw-threaded tips, adjustable nuts upon the screw-threaded tips, and a flame-confining device comprising a skeleton frame having a pair of cross-bars provided with perforations receiving the screw-threaded tips with the cross-bars resting upon and adjustable with the nuts, and a perforate hood supported upon and rising from the frame.

24. In an apparatus for making carbon-black, the combination with a carbon-collecting surface, of a carbon-producing burner having a screw-threaded nipple, an externally-screw-threaded burner-tip adjustably fitted to the screw-threaded portion of the nipple, a nut adjustably fitted upon the screw-threaded portion of the tip, and a flame-confining device supported upon and adjustable with the nut.

25. In an apparatus for making carbon-black, the combination with a cylindrical carbon-collecting device mounted to rotate upon a horizontal axis, of a carbon-producing burner having a plurality of burner-tips disposed in the vertical plane of the cylinder, with their upper ends arranged in an arc eccentric to that of the collecting-cylinder.

26. In an apparatus for making carbon black, the combination with a vertically-disposed rotatable carbon-collecting wheel, of a carbon-producing burner having a plurality of tips aligned transversely of the burner in the vertical plane of the wheel, the outer tips being nearer to the surface of the wheel than the inner tips.

27. In an apparatus for making carbon-black, the combination with a casing, of a gas-service pipe therein, a plurality of burners carried thereby and disposed transversely thereof, each burner having a plurality of screw-threaded nipples, externally-screw-threaded burner-tips adjustably fitted to the nipples, adjustable nuts fitted upon the outermost screw-threaded tips, an open frame embracing the tips and having cross-bars provided with openings loosely receiving the outermost tips with the cross-bars supported upon and adjustable with the nuts, an upstanding foraminous hood carried by the frame, a horizontal rotatable shaft aligned longitudinally above the gas-service pipe, a plurality of rotatable carbon-collecting wheels mounted upon the shaft and separated by vertical interspaces, each wheel having opposite flat carbon-collecting heads, supports carried within the casing and at opposite sides of the shaft, scrapers lying between the respective wheels in frictional engagement with the adjacent heads thereof to scrape the carbon therefrom and having their opposite ends carried by the respective supports, and individual weighted scrapers in frictional engagement with the peripheries of the respective wheels.

28. In an apparatus for making carbon-black, the combination with carbon-producing means, of rotatable carbon-collecting wheels having opposite flat carbon-collecting heads and flat peripheries, individual scrapers engaging the periphery of each wheel, and scrapers arranged between each pair of wheels to scrape the heads.

29. In an apparatus for making carbon-black, the combination with carbon-producing means, of a rotatable shaft located adjacent thereto, a plurality of hollow carbon-collecting wheels mounted thereon, each wheel having one flat integral head, a hub projected beyond the opposite side of the wheel, and a separate flat head applied to that side of the wheel having the projected hub portion forming a spacing device for the adjacent wheels.

30. In combination with the carbon-collecting means, the carbon-producing means arranged below and spaced from the carbon-collecting means, of flame-confining means arranged in the space between the carbon-collecting means and the carbon-producing means and adjustable independently of the carbon-producing means for the purpose described.

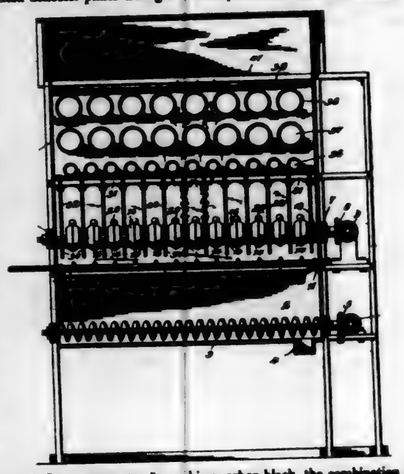
706,480. APPARATUS FOR MAKING CARBON-BLACK. JOHN H. MARS, Blandville, Pa., assignor to the Castle Brook Carbon Black Company, Williamsport, Pa. Filed Apr. 26, 1901. Serial No. 57,567. (No model.)

Claim.—1. In an apparatus for making carbon-black, carbon-producing means, a horizontally-disposed shaft, and carbon-collecting wheels carried thereby and spaced apart thereon and having wedge-shaped peripheries.

2. In an apparatus for making carbon-black, the combination with a series of gas-service burner-pipes, of a horizontally-disposed shaft, and carbon-collecting wheels carried thereby and spaced apart thereon and having wedge-shaped peripheries.

3. In an apparatus for making carbon-black, the combination with carbon-producing means, of a horizontally-disposed shaft carrying a series of vertically-disposed rotary carbon-collectors spaced apart to permit passage of air between them, and deflector-plates arranged in the spaces between the collectors.

4. In an apparatus for making carbon-black, the combination with carbon-producing means, of a series of vertically-disposed rotary carbon-collectors spaced apart to permit passage of air between them, and perforated deflector-plates arranged in the spaces between the collectors.



5. In an apparatus for making carbon-black, the combination with a series of gas-service burner-pipes, of a horizontally-disposed shaft arranged above the pipes and carrying vertically-disposed carbon-collectors spaced apart to permit passage of air between them, and deflector-plates arranged between the collectors.

6. In an apparatus for making carbon-black, the combination with carbon-producing means, of a horizontally-disposed shaft, wedge-faced carbon-collecting wheels carried by the shaft and spaced apart thereon, and scrapers coacting with the wheels.

7. In an apparatus for making carbon-black, the combination with carbon-producing means, a horizontally-disposed shaft, carbon-collecting wheels carried by the shaft and spaced apart thereon, and having wedge-shaped peripheries, and weighted scrapers having chisel scraping edges to coact with the wheels.

8. In an apparatus for making carbon-black, the combination with carbon-producing means, of a horizontally-disposed rotatable shaft, vertically-disposed carbon-collecting wheels carried by and spaced apart upon the shaft to permit a passage of air between the same, a support located adjacent to the shaft, and relatively fixed weighted scrapers independently mounted on the support in coöperative relation with the respective wheels for the purpose described.

9. In an apparatus for making carbon-black, the combination of a series of gas-service burner-pipes, a horizontally-disposed shaft carrying a series of carbon-collecting wheels arranged above said pipes and spaced apart on the shaft and having wedge-shaped peripheries, and scrapers shaped to conform to the peripheries of and to coact with the collecting-wheels.

10. In an apparatus for making carbon-black, the combination of a series of gas-service burner-pipes, a horizontally-disposed shaft carrying a series of carbon-collecting wheels arranged above said pipes and spaced apart on the shaft and having wedge-shaped peripheries, and weighted scrapers having chisel scraping edges shaped to conform to the peripheries of and to coact with the collecting-wheels.

11. In an apparatus for making carbon-black, the combination with carbon-producing means, a horizontally-disposed shaft carrying a series of carbon-collecting wheels spaced apart on the shaft to permit passage of air between them, scrapers coacting with the collecting-wheels and shaped to conform to the peripheries thereof, and perforated deflector-plates arranged in the spaces between the collecting-wheels.

12. In an apparatus for making carbon-black, the combination with carbon-producing means, of a horizontally-disposed shaft carrying a series of carbon-collecting wheels spaced apart on the shaft, deflector-plates arranged in the spaces between the wheels, and collecting-cylinders arranged above the spaces between the deflectors.

13. In an apparatus for making carbon-black, the combination of carbon-producing means, a horizontal shaft carrying carbon-collecting wheels spaced apart on the shaft to permit passage of air between them scrapers coacting with the carbon-collecting wheels, perforated deflector-plates arranged in the spaces between the collecting-wheels, and collecting-cylinders arranged above the deflector-plates.

14. In an apparatus for making carbon-black, the combination of carbon-producing means, a horizontally-disposed shaft carrying carbon-collecting wheels spaced apart thereon to permit passage of air between them, scrapers coacting with the carbon-collecting wheels, perforated deflector-plates arranged in the spaces between the said wheels, and open-ended collecting-cylinders arranged above the deflector-plates.

15. In an apparatus for making carbon-black, the combination of carbon-producing means, carbon-collecting wheels spaced apart to permit passage of air between them, scrapers coacting with the carbon-collecting wheels, perforated deflector-plates arranged in the spaces between the wheels, open-ended collecting-cylinders arranged above the deflector-plates, and a screen arranged above the upper series of collecting-cylinders.

16. In an apparatus for making carbon-black, the combination with carbon-producing means, of two shafts, each carrying a series of carbon-collecting wheels spaced apart on the shaft to permit passage of air between them, and being rotated in opposite directions, that is to say toward each other, scrapers coacting with the wheels, perforated deflector-plates arranged in the spaces between the wheels, open-ended collecting-cylinders arranged above the deflecting-cylinders, and a screen arranged above the upper series of collecting-cylinders.

17. In an apparatus for making carbon-black, a pair of substantially horizontal rotatable shafts, vertically-disposed carbon-collecting wheels carried by and rotatable with the shafts and separated by interspaces, carbon-producing burners disposed transversely of the shafts and located beneath the respective wheels, a support located between the shafts, and a series of independent weighted scrapers, one for each wheel, carried by the support and in frictional engagement with the respective wheels.

18. In an apparatus for making carbon-black, a pair of substantially horizontal rotatable shafts, carbon-collecting wheels mounted upon and rotatable with the shafts and separated by interspaces, carbon-producing burners arranged in groups transversely of the shafts and beneath the respective wheels, a support extending longitudinally between the shafts, and a series of individually-movable weighted scrapers, one for each wheel, and having their lower ends pivotally mounted upon the support and their upper portions inclined upwardly and outwardly and in frictional engagement with the respective collecting-wheels.

19. In an apparatus for making carbon-black, the combination of a series of gas-service burner-pipes suitably spaced apart, a horizontal shaft carrying a series of carbon-collecting wheels spaced apart upon the shaft, collecting-wheels arranged in the spaces between the collecting-wheels, and a plurality of series of open-ended collecting-cylinders arranged above the deflectors, the lowest series of cylinders being the smallest and constituting breakers operating initially to retard the currents of the products of combustion and then to direct such currents against the remaining series of collecting-cylinders.

20. In an apparatus for making carbon-black, the combination of a series of gas-service burner-pipes suitably spaced apart, carbon-collectors spaced apart to permit passage of air between them, perforated deflector-plates arranged on each side of the carbon-collectors, series of open-ended collecting-cylinders arranged above the deflectors, the lower series of cylinders being the smallest, and constituting breakers operating initially to retard the currents of the products of combustion and then direct them against the remaining series of collecting-cylinders, a screen arranged above the upper series of collecting-cylinders, and escape-passages arranged above the screen.

21. In an apparatus for making carbon-black, the combination with a suitably-inclosed casing, a hopper formed in the bottom thereof, a worm mounted in the lower portion of the hopper and operating to feed material to a chute arranged at one end of the hopper, carbon-collectors arranged within the casing and rotating in opposite directions, a series of gas-service burner-pipes arranged in a horizontal plane below the collectors and disposed in the arc of a circle with relation thereto, the collectors and gas-pipes being spaced apart to permit passage of air between them and also the deposition of carbon from the collectors past the pipes and into the hopper, scrapers coacting with the carbon-collectors, perforated deflector-plates arranged on each side of the carbon-collectors, a plurality of series of open-ended collecting-cylinders arranged above the deflectors, a screen arranged above the upper series of cylinders, and escape-passages formed in the roof of the casing adjacent to the screen.

22. In an apparatus for making carbon-black, a closed casing having its lower portion formed into a hopper provided at one end of the chute, a worm working in the hopper, a series of gas-service burner-pipes supported in horizontal position upon cross-sills within the casing, shafts carrying carbon-collectors spaced apart to permit passage of air between them, the actuating mechanism for the worm and for the carbon-collectors being on the exterior of the casing, thereby to protect such mechanism from an accumulation of carbon-black, scrapers coacting with the carbon-collectors, perforated deflector-plates arranged on each side of the carbon-collectors, open-ended collecting-cylinders arranged above the deflectors, a screen arranged above the upper series of the cylinders, and escape-passages formed in the roof of the casing adjacent to the screen.

23. In an apparatus for making carbon-black, the combination of carbon-producing means, and a vertically-disposed carbon-collecting wheel, the rim of which is formed with two opposite flat carbon-collecting surfaces, and a peripheral flame-dividing projection located at the junction of the carbon-collecting surfaces, the carbon-producing means being in alinement with the flame-dividing projection to direct the flame to opposite sides thereof and into coöperative relation with the carbon-collecting surfaces.

24. In an apparatus for making carbon-black, the combination with carbon-producing means, of a vertically-disposed rotatable carbon-collecting wheel, having its rim beveled inwardly from its opposite edges to provide opposite flat carbon-collecting surfaces, the pointed intersection of these faces forming a peripheral flame-dividing projection or partition.

25. In an apparatus for making carbon-black, the combination with carbon-producing means, of a plurality of vertically-disposed rotatable carbon-collecting wheels which are separated by interspaces, and partitions located in the interspaces between the carbon-collecting wheels and projected downwardly below the latter and toward the carbon-producing means, and also projected above the wheels.

26. In an apparatus for making carbon-black, the combination with carbon-producing means, of a plurality of vertically-disposed rotatable carbon-collecting wheels located above the carbon-producing means and separated by interspaces, vertical partitions in the interspaces and projected above and below the carbon-collecting wheels, and secondary carbon-collectors located above the wheels and opposite the spaces between the respective partitions.

27. In an apparatus for making carbon-black, the combination of carbon-collecting wheels which are separated by interspaces, carbon-producing means located under each wheel, scrapers for each wheel and vertical partitions situated in the interspaces and projected above and below the wheels.

28. In an apparatus for making carbon-black, the combination with carbon-producing means, of carbon-collectors located above the same and separated by interspaces, vertical partitions located in the interspaces and projected above the carbon-collectors, horizontal series of secondary carbon-collectors located transversely above the primary collectors and with one series above the other, the lowermost series having its members located opposite the space between adjacent partitions, and the members of the next-above series being staggered with respect to the members of the lowermost series.

29. In an apparatus for making carbon-black, the combination of a casing, a horizontal shaft mounted therein, a series of carbon-collecting wheels mounted thereon and spaced apart to permit the passage of air between the same, carbon-burners arranged beneath each carbon-collecting wheel, and perforated plates located between the burners and the carbon-collecting wheels to separate the wheels from each other and direct the flame thereto.

30. In an apparatus for making carbon-black, the combination with carbon-producing means, of a horizontally-disposed rotatable shaft located above said means, vertically-disposed carbon-collecting wheels carried by the shaft and having their hubs equally projected at corresponding ends to form means for regularly spacing the wheels, and independent scrapers in coöperative relation with the respective wheels.

31. In an apparatus for making carbon-black, the combination with carbon-producing means, of a horizontally-disposed shaft located above said means, vertically-disposed carbon-collecting wheels carried by the shaft and having their hubs provided with projected portions lying against the respective adjacent wheels and thereby spacing the latter, and independent scrapers in coöperative relation with the respective wheels.

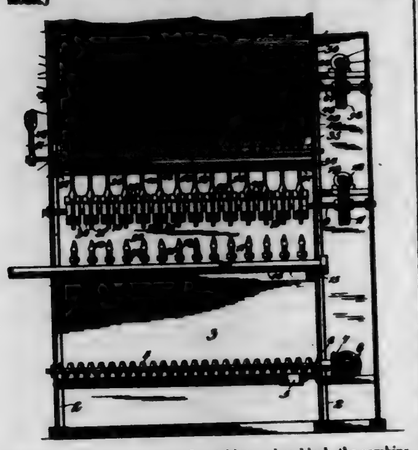
32. In an apparatus for making carbon-black, the combination with carbon-producing means, of a horizontally-disposed shaft located above said means, vertically-disposed carbon-collecting wheels carried by the shaft and having their hubs terminated flush at one end with the respective adjacent sides of the wheels, and the opposite ends of the hubs projected beyond the sides of the wheels and adapted to lie against the flush ends of the hubs to form spacing devices for the wheels, and independent scrapers in coöperative relation with the respective wheels.

33. In an apparatus for making carbon-black, the combination with carbon-producing means, of a horizontally-disposed shaft located above said means, a pair of vertically-disposed carbon-collecting wheels carried by the shaft, one of the wheels having a projected hub portion lying against the other wheel and forming a spacing device to separate the two wheels, and independent scrapers in coöperative relation with the respective wheels.

34. In an apparatus for making carbon-black, the combination with carbon-producing means, of a horizontally-disposed shaft, vertically-disposed carbon-collecting wheels carried by and spaced apart upon the shaft to permit a passage of air between the same, a support located adjacent

to the shaft, and scrapers, one for each wheel, independently mounted on the support in cooperative relation with the respective wheels, for the purpose described.

706,481. APPARATUS FOR MAKING LAMPBLACK. JOHN H. MANN, Mendville, Pa., assignor to the Castle Brook Carbon Black Company, Williamsport, Pa. Filed June 27, 1901. Serial No. 66,203. (No model.)



Claim.—1. In an apparatus for making carbon-black, the combination with carbon-producing means, of a vertically-rotatable carbon-collecting wheel having opposite flat collecting-surfaces the adjacent portions of which lie in the same plane, and flame-dividing means projecting beyond and lying between the said surfaces.

2. In an apparatus for making carbon-black, the combination with carbon-producing means, of a carbon-collecting wheel having a T-shaped collecting-face.

3. In an apparatus for making carbon-black, the combination with a carbon-collecting wheel having opposite flat collecting-surfaces and an intermediate circumferential flange located between said surfaces, of gas-burning means disposed to direct the flame against the flange.

4. In an apparatus for making carbon-black, a shaft, carbon-collecting wheels secured thereto and suitably spaced apart, each wheel being provided with opposite flat collecting-surfaces and an intermediate circumferential flange disposed at substantially right angles thereto, gas-burner pipes arranged below the said wheels and carrying tips disposed to conform to the periphery of and to impinge against the said flanges, and scraping means supported above the wheels and coacting with the collecting-surfaces.

5. In an apparatus for making carbon-black, the combination with carbon-producing means, carbon-collecting wheels, and scrapers coacting therewith, a revolvable open-work cylinder arranged above the carbon-collecting wheels, and means coacting with the cylinder to clear the same of accumulated carbon.

6. In an apparatus for making carbon-black, the combination with carbon-producing means, carbon-collecting wheels arranged above the same, scraping means coacting with the carbon-collecting wheels, an open-work cylinder above the carbon-collecting wheels, means for removing the accumulated carbon from the cylinder, and carbon-retaining means arranged above the cylinder.

7. In an apparatus for making carbon-black, the combination with suitable carbon-producing means, of an open-work carbon-collecting cylinder arranged above the same, means for removing the carbon from the cylinder, a collecting-chute arranged below the cylinder, and carbon-collecting means arranged above the cylinder.

8. In an apparatus for making carbon-black, the combination with a casing for suitable carbon-producing means, of a rotary carbon-collecting perforate cylinder arranged above the carbon-producing means, the ends of the cylinder being open, and escape-openings in the casing adjacent to the open ends of the cylinder, whereby to permit escape of heated air from the cylinder.

9. In an apparatus for making carbon-black, a casing for carbon-producing mechanism, an open-top roof, a hood so disposed over the roof as to prevent air-passages, and inclined screens connecting with the inner edges of the roof and with the top of the casing.

10. In an apparatus for making carbon-black, the combination with carbon-producing means, of a carbon-collecting wheel comprising two like portions suitably assembled, each comprising a hub portion, a plurality of arms, collecting-surfaces carried by the arms, and flanges carried by the collecting-faces.

11. In an apparatus for making carbon-black, the combination with suitable carbon-producing means, of an open-work carbon-collecting cylinder arranged above the same, a weight-controlled brush for removing the carbon from the cylinder, a collecting-chute arranged below the cylinder, and carbon-collecting means arranged above the cylinder.

12. In an apparatus for making carbon-black, the combination with suitable carbon-producing means, of an open-work carbon-collecting cylinder arranged above the same, means for removing the carbon from the cylinder, and a collecting-chute arranged below the cylinder.

13. In an apparatus for making carbon-black, the combination with carbon-producing means, of a hollow rotary perforate collecting-cylinder mounted over the carbon-producing means to collect the carbon and permit of the free escape of heated air, and a scraper in frictional engagement with the rotatable collector-cylinder.

14. In an apparatus for making carbon-black, the combination with carbon-producing means, of a hollow rotary collecting-cylinder formed of metallic netting and mounted over the carbon-producing means to collect the carbon and permit of the free escape of heated air, and a scraper in frictional engagement with the rotatable collecting-cylinder.

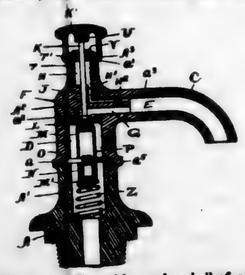
15. In an apparatus for making carbon-black, the combination with carbon-producing means, of a pair of primary carbon-collectors located above the carbon-producing means and separated by an interspace, a rotatable secondary carbon-collector located above and aligned with the interspace between the primary collectors, a scraper in frictional engagement with the lower side of the secondary collector, and a chute located between the primary and secondary collectors and constructed to receive the carbon scraped from the secondary collector and to discharge the same downwardly through the interspace between the primary collectors.

16. In an apparatus for making carbon-black, the combination with carbon-producing means, and a rotatable carbon-collector located above said means, of a support located above the carbon-collector, and a scraper having its upper end provided with a hook which is detachably engaged with the support to pivotally mount the scraper, the latter being normally in contact with the carbon-collector.

17. In an apparatus for making carbon-black, the combination of a horizontal shaft, a series of vertically-disposed carbon-collecting wheels carried thereby and separated by interspaces, and a plurality of carbon-producing burners disposed below the respective wheels, each burner having a plurality of tips which are individually adjustable in a vertical direction and disposed in an arc of a circle.

18. In an apparatus for making carbon-black, the combination of a horizontal shaft, vertically-disposed carbon-collecting wheels carried thereby and separated by interspaces, and carbon-producing burners corresponding to and located below the respective wheels, each burner having a plurality of upstanding screw-threaded nipples which increase in length outwardly from an intermediate nipple, and burner-tips fitted to and individually adjustable in a vertical direction in the screw-threaded portions of the respective nipples and disposed in the arc of a circle.

706,482. SELF-CLOSING VALVE. FREDERIC H. MASON, Spokane, Wash. Filed Dec. 13, 1901. Serial No. 40,940. (No model.)



Claim.—1. The combination with a valve-shell of a valve-closing with an opening against the fluid-pressure, and a fluid-cushion cylinder and piston within the valve-shell immersed in and its interior communicating with the fluid under pressure, one part of the cushion being connected to the shell and the other part thereof to the valve, the cylinder of said fluid-cushion being closed at both ends and having its communication with the valve-chamber at its middle portion, substantially as specified.

2. The combination with a valve-shell of a valve closing with and opening against the fluid-pressure, a fluid-cushion cylinder and piston within the valve-shell immersed in and its interior commencing with the fluid under pressure as its interior space expands or contracts in operation, one part of the cushion being connected to the shell and the other part thereof to the valve and movable therewith, said fluid-cushion cylinder being closed at both ends and having ingress and egress opening for the fluid at its middle portion, said fluid-cushion retarding and steadying the movement of the valve in both directions, substantially as specified.

3. The combination with a valve-shell of a valve closing with and opening against the fluid-pressure, and a fluid-cushion cylinder and piston within the valve-shell immersed in and its interior communicating with the fluid under pressure, one part of the cushion being connected to the shell and the other part thereof to the valve, said fluid-cushion cylinder being closed at both ends and having slots in its middle portion for the fluid to pass in and out, substantially as specified.

4. The combination with a valve-shell of a valve closing with and opening against the fluid-pressure, of a double-acting fluid-cushion piston and cylinder immersed in and its interior communicating with the fluid under pressure within the valve-shell, and connections for operating said fluid-cushion by movement of the valve in either direction, the cylinder of said fluid-cushion being closed at both ends, substantially as specified.

5. The combination with a valve of a valve-shell having two screw-threaded parts or sections, a transverse pin fitting between said sections, and a two-part fluid-cushion, one part connected to the valve-shell by said transverse pin and the other part connected to the valve, substantially as specified.

6. The combination with a valve of a valve-shell having two screw-threaded sections, a transverse pin fitting between said sections, a fluid-cushion piston secured to said pin, and a fluid-cushion cylinder connected to the valve and having slots to receive said pin, substantially as specified.

7. The combination with a valve of a valve-shell having two screw-threaded sections, a transverse pin fitting between said sections, a fluid-cushion piston secured to said pin, and a fluid-cushion cylinder connected to said valve and having slots to receive said pin, said pin having a screw-threaded connection with said fluid-cushion piston, substantially as specified.

8. The combination with a valve-shell and valve, of a fluid-cushion immersed in and its interior communicating with the fluid under pressure within said shell, and composed of two telescopic parts one connected to the valve-shell and the other to the valve, and operating to cushion and steady the movement of the valve, the outer or cylinder part of said fluid-cushion being closed at both ends, substantially as specified.

9. The combination with a valve-shell and valve, of a fluid-cushion immersed in and its interior communicating with the fluid under pressure within said shell, and composed of two telescopic parts one connected to the valve-shell and the other to the valve, and operating to cushion and steady the movement of the valve, the outer telescopic part or cylinder of said fluid-cushion being closed at both ends and having openings at its middle portion for ingress and egress of the fluid, said valve-shell having a drainage-chamber and a drainage-channel leading therefrom to the delivery chamber or orifice of the shell, said valve-shell having a contracted outlet-channel leading from said valve-chamber to said delivery-chamber and coöperating with said drainage-channel to draw or suck the liquid out of the drainage-chamber, substantially as specified.

10. The combination with a valve-shell and valve, of a fluid-cushion immersed in and its interior communicating with the fluid under pressure within said shell, and composed of two telescopic parts one connected to the valve-shell and the other to the valve, and operating to cushion and steady the movement of the valve, the outer telescopic part or cylinder of said fluid-cushion being closed at both ends and having openings at its middle portion for ingress and egress of the fluid, said valve-shell having a cushion-chamber, a valve-chamber, a delivery chamber or orifice, a contracted outlet-channel leading from said valve-chamber to said delivery-chamber, a drainage-chamber, and a drainage-channel terminating in said delivery-chamber adjacent to said outlet-channel, and having a portion parallel to said outlet-channel, the fluid flow and pressure in the contracted outlet-channel operating to draw or suck the liquid out of the drainage chamber and channel, substantially as specified.

11. The combination with a valve-shell and valve, of a fluid-cushion immersed in and its interior communicating with the fluid under pressure within said shell, and composed of two telescopic parts one connected to the valve-shell and the other to the valve, and operating to cushion and steady the movement of the valve, the outer telescopic part or cylinder of said cushion being closed at both ends and having openings at its middle portion for ingress and egress of the fluid, substantially as specified.

12. The combination with a valve-shell of a valve and valve-stem, a fluid-cushion piston and cylinder, the latter having a shouldered screw-threaded end upon which the valve is mounted and to which the valve-stem is secured, substantially as specified.

13. The combination with a valve-shell of a valve and valve-stem, a fluid-cushion piston and cylinder, the latter having a shouldered screw-threaded end upon which the valve is mounted and to which the valve-stem is secured, and said cushion-cylinder having a removable plug closing its opposite end, substantially as specified.

14. The combination with a valve and valve-stem, of a valve-shell having two sections or fittings screw-threaded together, a transverse pin fitting between the meeting ends of said sections, a fluid-cushion piston and cylinder, one secured to said transverse pin and the other slotted to reciprocate in respect thereto, substantially as specified.

15. The combination with a valve and valve-stem of a valve-shell, having two screw-threaded sections, a transverse pin between the meeting ends of said sections, a fluid-cushion piston secured thereto, a reciprocating fluid-cushion cylinder having longitudinal slots to receive said pin, and a cap on the upper end of said valve-stem, said cap and valve-shell having a longitudinal groove and pin to prevent rotation, substantially as specified.

16. The combination with a valve and valve-stem of a valve-shell, having two screw-threaded sections, a transverse pin between the meeting ends of said sections, a fluid-cushion piston secured thereto, a reciprocating fluid-cushion cylinder having longitudinal slots to receive said pin, a shouldered end to receive said valve, and screw-threads to receive the valve-stem, substantially as specified.

17. The combination with a valve and valve-stem of a valve-shell, having two screw-threaded sections, a transverse pin between the meeting ends of said sections, a fluid-cushion piston secured thereto, a reciprocating fluid-cushion cylinder having longitudinal slots to receive said pin, a shouldered end to receive said valve, screw-threads to receive the valve-stem, and a nut () to hold the valve in place, substantially as specified.

18. The combination with a valve and valve-stem of a valve-shell, having two screw-threaded sections, a transverse pin between the meeting ends of said sections, a fluid-cushion piston secured thereto, a reciprocating fluid-cushion cylinder having longitudinal slots to receive said pin, a shouldered end to receive said valve, and a removable screw-plug a its opposite end, substantially as specified.

19. The combination with a valve and valve-stem of a valve-shell, having two screw-threaded sections, a transverse pin between the meeting ends of said sections, a fluid-cushion piston secured thereto, a reciprocating fluid-cushion cylinder having longitudinal slots to receive said pin and a cap on the upper end of said valve-stem, said cap and valve-shell having a longitudinal groove and pin to prevent rotation, said longitudinal slots in the cushion-cylinder and in the valve-stem cap having transverse slots to adapt the valve to be held open, substantially as specified.

20. The combination with a valve and valve-stem, of a valve-shell having two sections or fittings screw-threaded together, a transverse pin fitting between the meeting ends of said sections, a fluid-cushion piston and cylinder, one secured to said transverse pin and the other slotted to reciprocate in respect thereto, one of said screw-threaded sections of the valve-shell having notches or recesses in its end to receive said transverse pin, substantially as specified.

21. The combination with a bowl or vessel of a valve-shell, a valve therein closing with and opening against the fluid-pressure, a horizontally-extending valve-stem having a cap or knob on its outer end, and an upright wall or slab through which the valve-stem projects and behind which the valve-shell and its supply-pipe and discharge-tube connections fit, whereby the valve is rendered less capable of being tied open, substantially as specified.

22. The combination with a bowl or vessel, a valve therein closing with and opening against the fluid-pressure, a fluid-cushion composed of two telescopic parts, one connected to the valve-shell and the other to the valve, a horizontally-extending valve-stem having a cap or knob on its outer end, and an upright wall or slab through which the valve-stem projects and behind which the valve-shell and its connections fit, whereby the valve is rendered less capable of being tied open, substantially as specified.

23. The combination with a valve of a valve-shell having two screw-threaded parts or sections, a transverse pin fitting between said sections, and a two-part fluid-cushion, one part connected to the valve-shell by said transverse pin and the other part connected to the valve, said valve-shell having a valve-seat and valve-chamber, a drainage-chamber, a delivery or discharge chamber, an escape-outlet connecting the valve-chamber and delivery-chamber, and a drainage-outlet connecting the drainage-chamber and delivery-chamber, substantially as specified.

24. The combination with a valve-shell, of a valve and a fluid-cushion immersed in the fluid under pressure in the valve-shell and composed of two telescopic parts, one connected to the valve-shell and the other to the valve, the outer or cylinder part of said fluid-cushion being closed at both ends and having an ingress and egress opening for the fluid at its middle portion, substantially as specified.

25. The combination with a valve-shell of a valve closing with and opening against the fluid-pressure, a fluid-cushion cylinder and piston within the valve-shell immersed in and its interior communicating with

the fluid under pressure, one part of the cushion being connected to the shell and the other part thereof to the valve, the outer or cylinder part of said fluid-cushion being closed at both ends and having an ingress and egress opening for the fluid at its middle portion and a supplemental means to aid the water-pressure inclosing the valve, substantially as specified.

26. The combination with a valve-shell of a valve closing with and opening against the fluid-pressure, a fluid-cushion cylinder and piston within the valve-shell immersed in and its interior communicating with the fluid under pressure, one part of the cushion being connected to the shell and the other part thereof to the valve, the outer or cylinder part of said fluid-cushion being closed at both ends and having an ingress and egress opening for the fluid at its middle portion and a spring to supplement or aid the water-pressure in closing the valve when the water-pressure is low or wanting, substantially as specified.

27. The combination with a valve-shell of a valve closing with and opening against the fluid-pressure, and a fluid-cushion cylinder and piston within the valve-shell immersed in and its interior communicating with the fluid under pressure, one part of the cushion being connected to the shell and the other part thereof to the valve, the outer telescopic part or cylinder of said fluid-cushion being closed at both ends and having openings at its middle portion for ingress and egress of the fluid, said valve-shell having a cushion-chamber D, delivery-chamber E, valve-chamber F and a comparatively small outlet-channel G connecting said chambers E and F, a drainage-chamber and drainage-channel leading into said delivery-chamber at the end of said contracted outlet-channel G to cause the flow of the liquid under pressure to draw out or suck the liquid from the drainage chamber and channel, substantially as specified.

28. The combination with a valve-shell of a valve closing with and opening against the fluid-pressure, and a fluid-cushion cylinder and piston within the valve-shell immersed in and its interior communicating with the fluid under pressure, one part of the cushion being connected to the shell and the other part thereof to the valve, the outer telescopic part or cylinder of said fluid-cushion being closed at both ends and having openings at its middle portion for ingress and egress of the fluid, said valve-shell having a delivery-chamber E, valve-chamber F and a comparatively small outlet-channel G connecting said chambers E and F, a drainage-chamber and drainage-channel leading into said delivery-chamber at the end of said contracted outlet-channel G to cause the flow of the liquid under pressure to draw out or suck the liquid from the drainage chamber and channel, substantially as specified.

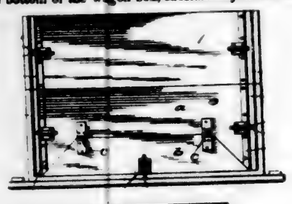
29. The combination with a valve-shell of a valve closing with and opening against the fluid-pressure, and a fluid-cushion cylinder and piston within the valve-shell immersed in and its interior communicating with the fluid under pressure, one part of the cushion being connected to the shell and the other part thereof to the valve, the outer telescopic part or cylinder of said fluid-cushion being closed at both ends and having openings at its middle portion for ingress and egress of the fluid, said valve-shell having a cushion-chamber D, delivery-chamber E, valve-chamber F, and a comparatively small outlet-channel G connecting said chambers E and F, drainage-chamber H and drainage-channels H', H^2, said channel H^2 extending parallel to said channel G, substantially as specified.

706,433. CUT-OFF DEVICE FOR TRAIN-LINES. GILBERT C. MOORE, Guntown, Miss. Filed Mar. 17, 1902. Serial No. 98,585. (No model.)

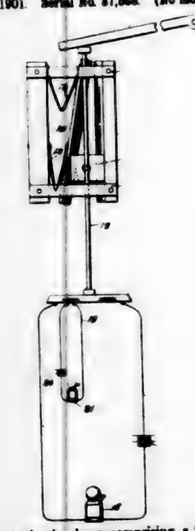
Claim.—The combination with a train-line, of a two-way cock mounted in said line and provided with a lever extending at an angle to the said train-line when the valve is open, a chain connected to said lever and bearing a snap-hook, and a chain bearing a snap engaging said first-mentioned snap and having grasping resilient jaws constructed to hold said snap until said lever is straightened out and to release said snap when the pull becomes greater and thereby avoid breaking the chains, substantially as described.

706,434. END-BOARD FOR FARM-WAGONS. CLYDE S. MOSER, Shabbona, Ill. Filed June 5, 1902. Serial No. 110,367. (No model.)

Claim.—The combination with the side-boards of a wagon, of an end-board consisting of two sections, cleats secured to the inner sides of the side-boards and provided with vertically-disposed slots and with a recess or keeper, said slots having contracted entrances, angle-plates secured to the ends of the sections of the end-board and provided with heads and shanks which correspond in shape and fit said vertical slots, one of said sections of the end-board being divided into two parts, which parts are hinged together, locks connected to the sections of the end-board and adapted to engage the keepers of the cleats, and a lock connected to the hinged part of one of the end-board sections and adapted to engage a keeper in the bottom of the wagon-box, substantially as set forth.



706,435. CIRCUIT-CLOSER. DAVID F. MULKEY, Soddy, Tenn. Filed Dec. 31, 1901. Serial No. 87,863. (No model.)



Claim.—1. A circuit-closer comprising a fixed guide, a movable guide, springs engaging near opposite ends thereof whereby it may move in angular relation to the fixed guide, a block movable along the guides, and a contact carried by the block, substantially as specified.

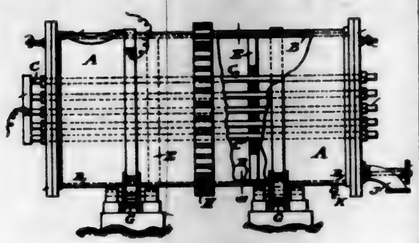
2. A circuit-closer, comprising a frame, a side member of which forms a guide, a spring-pressed guide in the frame, a block movable along said guides, a rod carried by said block, a contact connected to the rod, and means for moving the rod in one direction, substantially as specified.

3. A circuit-closer, comprising a frame, one member of which forms a guide, a movable guide in the frame, spring connections near opposite ends of said movable guide and the frame, a block movable along said guides, a rod carried by the block, a plurality of contacts carried by the rod, and a lever for moving said rod to circuit-closing position, substantially as specified.

706,436. APPARATUS FOR THE ELECTROLYTICAL TREATMENT OF ORES OR SLIMES. FRANK T. MUNFORD, Kalgoorlie, Western Australia, Australia. Filed Sept. 30, 1901. Serial No. 77,077. (No model.)

Claim.—1. An apparatus for the extraction of metals from their ores and slimes, comprising a metallic drum, a copper lining therein, means to maintain said lining continually amalgamated, a trailing electrical contact for the drum, a plurality of conductive bars passing longitudinally through the drum and insulated therefrom, and means to rotate said drum substantially as described.

2. An apparatus for the extraction of metals from their ores and slimes, comprising a rotatable cylindrical metallic drum, a copper lining therein, a body of mercury in the drum to maintain the lining amalgamated, a valve-controlled inlet and outlet, and a relief-valve at one end, a plurality of conductive rods insulated from and passing longitudinally through the drum, a metallic ring connecting the bars, trailing electrical contact for the drum and one for said ring, substantially as described.



706,487. MACHINE FOR HANDLING VEHICLES. GEORGE R. MYERS and JESSE S. MYERS, St. Joseph, Mo. Filed Feb. 5, 1901. Serial No. 46,142. (No model.)

Claim.—1. The improved apparatus for the use specified, comprising parallel tracks which gradually increase in elevation from front to rear, two separate trucks, adapted to run on said tracks one immediately in front of the other, side supports for wheels of vehicles to be run on the said tracks, each supports being lower than the highest elevation of said tracks, and the trucks having top portions with which the vehicle-axles come into contact as the vehicle is pushed over the tracks, substantially as shown and described.

2. An apparatus for handling and cleaning vehicles, comprising tracks resting upon ground or floor, two separate sets of tracks, each set bearing a framework of its own, the one set of tracks running on the tracks immediately in front of the other set, and unconnected with each other in any way, and having inclined top portions as described, whereby vehicles of different lengths may be elevated as and for the purpose specified.

3. An apparatus for handling and cleaning vehicles consisting of track and front and rear trucks, the upper framework of rear truck being stationary or fixed, and inclined with lower end to front of track adapted for having vehicles whose rear axles may be of different heights readily accommodated thereon, substantially as described.

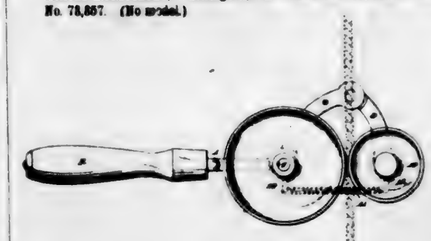
4. An apparatus for handling and cleaning vehicles consisting of track and front and rear trucks, the one set of trucks immediately in front of the other, the front truck so constructed, that the framework forming the upper part thereof is free to move up and down at rear end, and is provided with suitable contrivances for raising and lowering and holding in place, and adapted for collapsing so as to allow the rear axle of vehicle to clear it and to be raised to allow front axle to rest thereon and held there while vehicle is being handled, substantially as shown and for the purpose specified.

5. An apparatus for handling and cleaning vehicles consisting of track and trucks, the one set of trucks immediately in front of the other, and the front set being provided with an automatic release, adapted for tripping and causing the upper framework of front truck, when elevated at rear end to collapse, thereby releasing front axle of vehicle and allowing rear axle to pass over front truck unobstructed, substantially as shown and for the purpose specified.

6. In an apparatus for the purpose specified, the combination, with a track gradually increasing in height, of a truck adapted to run thereon and having a hinged top portion which is vertically adjustable at one end, a ratchet-bar pendent from the latter, a pivoted lever having a pawl adapted to engage said ratchet-bar, and a releasing device or trip pivoted to the truck and having a projecting arm, and a fixed obstruction on the track with which the trip comes in contact in the manner described.

7. In an apparatus for the purpose specified, the truck having a hinged top which is free at one end, a ratchet and pawl for locking the same in different elevations, and a pivoted lever one end of which is adapted to engage said free end of the adjustable top, for raising it, as shown and described.

706,438. MEASURING DEVICE FOR ARTESIAN WELLS. SAMUEL MCCAVERTEY, Washington, Pa. Filed Oct. 16, 1901. Serial No. 78,857. (No model.)



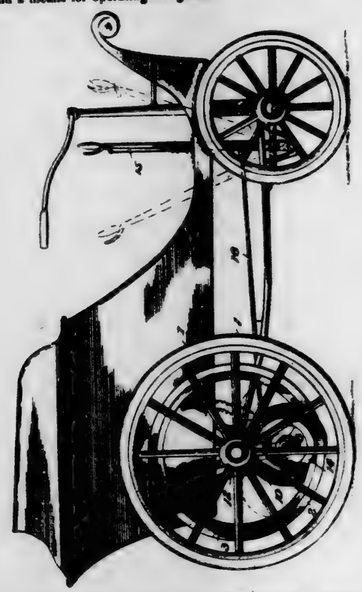
Claim.—1. In a device for measuring the depth of wells, a frame having a handle secured to one end thereof and a shaft journaled in the other end, one end of said shaft extending into the casing of a register for the purpose of operating the register, a drive-wheel rigidly mounted on said shaft, an upwardly-extending arm secured to the frame, a downwardly-extending bracket-arm pivotally secured to the upper end of said first-named arm, a pulley journaled in the lower extremity of said bracket-arm between which and said drive-wheel the rope passes, and a spring connected to said bracket-arm for normally holding the rope in engagement with the drive-wheel, substantially as described.

2. In a device for measuring the depths of wells, a frame having a handle secured to one end thereof, a hub carried by the other end of the frame and having a shaft journaled therein, a drive-wheel having a milled periphery secured to one end of said shaft, the other end of said shaft extending into the casing of the register, for the purpose of operating the register, an arm carried by the hub and extending above said drive-wheel, a bracket-arm pivotally secured to said arm and carrying a revolnble pulley in alinement with said drive-wheel, lugs carried by the hub and the bracket-arm, and a spring connected to said lugs for holding the rope between said drive-wheel and pulley, substantially as described.

706,439. MOTOR-VEHICLE. HARRY M. MCCALL, Pittsburg, Pa., assignor of five-eighths to James Rees Sons' Company, Pittsburg, Pa. Filed Mar. 7, 1902. Serial No. 97,077. (No model.)

Claim.—1. A motor-vehicle consisting of a traction-wheel having a track concentrically located thereon, a motor-shaft having a disk adapted to engage said track, and a suitable guide for the motor-shaft, whereby the said shaft may be moved in the arc of a circle about the center of the traction-wheel, a means for operating the guide, a motor mounted on said shaft, the weight of the motor, the shaft and their attachments being borne by the said track.

2. A motor-vehicle consisting of a traction-wheel, a track concentrically arranged upon said traction-wheel, a motor having its armature fixed to a motor-shaft, said motor-shaft having at its end a disk adapted to engage said track, a guide adapted to move said shaft and its attachments in the arc of a circle, a means for supporting the field of the motor and hold it against revolution, but permit it to rotate in the arc of a circle and a means for operating the guide.



3. A motor-vehicle consisting of a traction-wheel, a track concentrically arranged on said traction-wheel, a motor consisting of an armature and a field, a support for said field adapted to retain it against revolution, but permit it to rotate in the arc of a circle, a motor-shaft fixed to said armature, a disk carried by said motor-shaft and adapted to engage said track, a guide adapted to move said shaft and its attachments in the arc of a circle, and a means for operating said guide.

4. A motor-vehicle consisting of a traction-wheel, a track concentrically arranged upon said traction-wheel, a motor-shaft, a disk arranged on said shaft and adapted to engage said track a guide adapted to rotate said shaft in the arc of a circle, said guide having at its lower end an elongated opening receiving said motor-shaft and a means for operating the motor-shaft and said guide.

5. A motor-vehicle consisting of a traction-wheel, a track concentrically arranged upon said traction-wheel, a motor-shaft adapted to rotate in the arc of a circle, a disk attached to said shaft and adapted to engage said track, a guide having an elongated opening, a sliding box carried by said opening, said motor-shaft being journaled in said box, and a means for operating the motor-shaft and the guide.

6. A motor-vehicle consisting of a traction-wheel, a track concentrically arranged upon said wheel, a motor consisting of an armature and a field, a motor-shaft fixed to said armature, a disk carried by said motor-shaft, said disk adapted to engage said track, a guide adapted to move said motor-shaft and its attachments in the arc of a circle, a means for operating said guide, guides for the motor-field, said guides being so constructed, arranged and connected with the motor-field whereby the same is held from rotation, but permitted to move in the arc of a circle.

706,440. COMBINED DEFLECTOR AND SCREEN. CHARLES R. MCCLURE, Chicago, Ill., assignor of one-half to Charles F. Quiney, Chicago, Ill. Filed Jan. 13, 1902. Serial No. 89,569. (No model.)

Claim.—1. The combination with a removable window-screen for car-windows, of a deflector pivotally secured thereto at the end thereof toward the direction of movement of the car, and a spring interposed between said screen and said deflector tending to maintain the deflector in a plane at substantially right angles to said screen, but permitting said deflector to fold against the screen.

2. The combination with a removable window-screen comprising hinged sections adapted to be folded upon each other when the screen is removed from the window, of a deflector pivotally secured to an end of one section of said screen, and means for normally maintaining said deflector in a plane transverse to that of the screen, said deflector being of a length less than that of the sections of the screen and thereby adapted to lie between said sections when they are removed from the window and folded together.

3. The combination with a removable window-screen for car-windows, of a deflector pivotally secured thereto, lugs projecting from said screen, and a spring interposed between said screen and said deflector tending to retain the deflector in contact with said lugs, but permitting the deflector to fold against the screen.

4. The combination with a removable window-screen, of a deflector, hinges pivotally securing said deflector to said screen, integral lugs on said hinges projecting at substantially right angles to the plane of the screen, and a spring interposed between said screen and said deflector tending to retain the deflector in contact with said lugs, but permitting the deflector to fold against the screen.

5. The combination with a window-screen, of a deflector, brackets secured to said screen, integral lugs projecting from said brackets, a rod supported by said brackets around which portions of the deflector are bent, a spring surrounding said rod and engaging said deflector and said screen whereby the former is maintained in contact with said lugs.

706,441. PULP-SEPARATOR. JEREMIAH K. MCLAUGHLIN, Au Sable Forks, N. Y. Filed Oct. 4, 1901. Serial No. 77,564. (No model.)

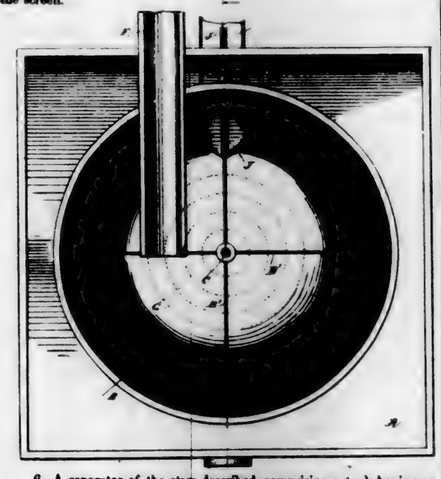
Claim.—1. In a separator of the class described, the combination of a vertical shaft, a funnel-shaped screen revoluble with said shaft, and successively smaller deflectors carried by said shaft within said screen and having working surfaces inclined oppositely to the taper of said screen.

2. In a separator of the class described, the combination of a vertical shaft having jet-openings, a screen, and hollow conical deflectors carried by the shaft and having their inner surfaces opposite to said jet-openings, said conical deflectors having their active surfaces inclined to the active surface of said screen.

3. In a separator of the class described, the combination of a vertical shaft having jet-openings, a revoluble screen, means for feeding pulp to the upper end of the screen, and a series of conical deflectors mounted on the shaft and disposed in the path of the pulp discharged by the feed mechanism, said deflectors adapted to be flushed by jets from the shaft-openings.

4. A separator of the class described, comprising a tank having an acid-outlet, a funnel-shaped screen mounted to rotate on a vertical axis, an outlet communicating with the apex end of said screen, and a plurality of conical deflectors arranged within said screen and having their active surfaces inclined in opposite directions to the taper of the screen.

5. A separator of the class described, comprising a tank having an acid-outlet, a funnel-shaped screen mounted within said tank and adapted to rotate on a vertical axis, a pulp-outlet connected with the apex end of the screen, means for feeding pulp to the upper end of said screen, and deflectors mounted within and revolvable with said screen, said deflectors having their active surfaces inclined in opposite directions to the taper of the screen.



6. A separator of the class described, comprising a tank having an acid-outlet, a funnel-shaped screen mounted to rotate on a vertical axis and within said tank, a pipe provided with a head which communicates with the apex end of said screen, a cap fitted to the apex end of the screen and extending over the open end of said head, and a series of conical deflectors mounted within said screen and having their active surfaces inclined in an opposite direction to the taper of the screen.

7. A separator of the class described, comprising a tank, a vertical hollow shaft provided with jet-openings, a funnel-shaped screen revolvable on a vertical axis, and conical deflectors carried by said shaft and disposed adjacent to said jet-openings, said deflectors having their active surfaces inclined inwardly from the surface of the screen.

8. A separator of the class described, comprising a perforated vertical shaft, a funnel-shaped screen mounted on said shaft, and conical deflectors mounted within the screen and disposed in the path of the jets from said perforated shaft, said deflectors having their active surfaces inclined in opposite directions to the taper of the screen.

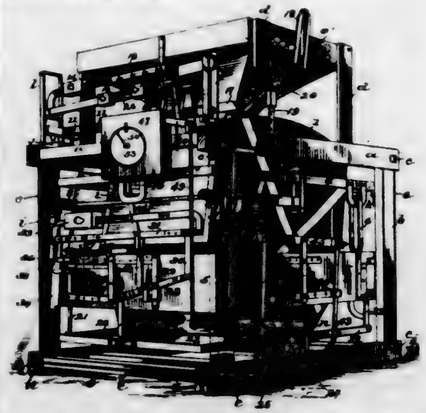
9. A separator of the class described, comprising a tank, a funnel-shaped screen mounted to rotate on a vertical axis and within said tank, means for feeding pulp at the foot of the screen, a series of conical deflectors disposed within the screen and having their active surfaces inclined in opposite directions to the taper of the screen, and an inclined perforated pipe disposed outside of the screen and adjacent to the surface thereof, as and for the purpose described.

706,442. AUTOMATIC GRAIN-WEIGHER. ANDREW MCLEOD and JOHN H. MCLEOD, Marietta, Kans. Filed Aug. 17, 1901. Serial No. 72,375. (No model.)

Claim.—1. In a weighing-machine, the combination, with a fixed supporting-frame, a movable lever-supported frame, a weighing-hopper pivoted in the latter, and a weighing-beam connected with the levers supporting said movable frame, of a lever, pivoted at one end below the said frame and extending alongside the lower portion of the hopper, and a device which pivotally connects such lever and the lower end of the hopper, and locks the latter in position for receiving a load, and then shifts to a new locking position when a portion of the load has been received by the hopper, substantially as shown and described.

2. In a weighing-machine, the combination, with a fixed supporting-frame, a weighing-beam, a tiltable weighing-hopper, and a supporting-frame for the latter, of a lever pivoted at one end to bars pendent from the hopper-supporting frame, and a toggle-bar, which is pivoted to both lever and hopper, and normally assumes an inclined position and supports the said lever until the load is received in the hopper, when it releases the latter, to allow discharge of the load, substantially as shown and described.

3. In a weighing-machine, the combination, with a tiltable, weighing-hopper, a frame in which it is suspended, a weighing-beam, and intermediate levers connected with said beam and hopper, of a lever pivotally connected with the hopper-supporting frame, a device attached to the lower end of the hopper and connected with the said lever at a point removed from its fulcrum, means for locking the said lever temporarily when raised to a certain position by a partial load in the hopper, and means connected with the weighing mechanism whereby the locking means is tripped when the full load is received in the hopper, and whereby the hopper is released and allowed to shift for discharging the load, substantially as shown and described.



4. In a weighing-machine, the combination, with a tiltable hopper, a frame in which it is hung, weighing-beam, and levers supporting the hopper and connected with said beam, of a lever, 22, pivotally connected at its fulcrum end with the hopper-supporting frame, a vertical slidable stop, and lever connected with the same, means for connecting said lever with the aforesaid lever 22, and a locking device connecting the latter with the hopper, said device being so arranged that the lever 22 is elevated when the hopper receives its load and the stop is released, substantially as shown and described.

5. In a weighing-machine, the combination with a weighing-beam, a tiltable weighing-hopper, and levers supporting the latter and connected with said beam, of devices connected with the lower portion of the hopper for locking it in position to receive a load, means operatively connecting such locking devices with the hopper-supporting levers, whereby said devices are tripped to allow automatic release of the hopper when loaded as shown and described.

6. In a weighing-machine, the combination, with the tiltable weighing-hopper, a frame in which said hopper is hung, the weighing-beam, and interposed levers connected with the latter and supporting the hopper, of a lever 22 pivotally connected with the hopper-supporting frame, toggle-bars pivoted to said lever and the lower portion of the hopper, and normally assuming an inclined position when the hopper is in position to receive the load, a vertical slidable bar provided with a shoulder, a fixed stop engaged by said shoulder, means for holding the said bar normally engaged with the stop, a lever pivotally connected with the bar and supporting the same, means for connecting such lever with the lever to which the toggle-bar is attached, and a device connected with the intermediate weighing-levers for tripping the locking-bar, to allow the hopper to shift when the load is complete, substantially as shown and described.

7. In a weighing-machine, the combination, with a tiltable weighing-hopper, weighing-beam, and levers suspending the hopper, of a stop-bar, and lever mechanism connecting it with the hopper, whereby the latter is held in normal position, a toggle-lever for holding said stop-bar in locking position, the said lever mechanism having a contact-piece suitably arranged for depressing the toggle-lever and forcing it back to place after the hopper has made its complete shifting movement, as shown and described.

8. In a weighing-machine, the combination, with the tiltable hopper, the weighing-beam, and weighing-levers interposed and supporting the hopper, of a slidable bar having a shoulder adapted to engage a fixed stop, a toggle-lever and a movable device to which said lever is attached for holding the locking-bar fixed in normal position, a lever to which said bar is pivoted and by which it is supported, means connecting said lever with the lower portion of the hopper whereby the latter is held locked in position to receive the load, and a trip device connected with the weighing mechanism, and which, when the hopper is loaded, descends and trips the toggle-lever and thereby releases the locking device, substantially as shown and described.

9. In a weighing-machine, the combination, with the tiltable weigh-

ing-hopper, a weighing-lever and interposed levers from which the hopper is suspended, of a lever 22 pivoted at one end, a toggle-bar, or lever, connecting the lever 22 with the lower portion of the hopper, whereby when the load is nearly sufficient the toggle is shifted and lever 22 is raised, a registering mechanism, and a lever connected therewith, and arranged in position to be acted upon when the said lever 22 is raised, substantially as shown and described.

10. In a weighing-machine, the combination, with a receiving-hopper, the weighing-hopper, the weighing-beam, and levers interposed between it and the weighing-hopper, and supporting the latter, of a cut-off for the receiving-hopper; means for suspending it whereby it is adapted to swing beneath the said hopper, weighted levers connected with the cut-off, a lever pivoted at one end and arranged adjacent to the lower portion of the hopper and a toggle-bar connecting said lever with the hopper, whereby the weighted levers are released and allowed to shift the cut-off beneath the discharge of the receiving-hopper when the weighing-hopper has received a portion of its load, substantially as shown and described.
